LEVITICUS, in the Bible, the third book of the Pentateuch. The name is derived from that of the Septuagint version (τῆ Ληβίτικος, though the English form is due to the Latin rendering, Leviticus (sc. liber). By the Jews the book is called Wawjirêh (אֲוֹיִרְוֹה) from the first word of the Hebrew text; it is also referred to (in the Talmud and Masorah) as Tsêrath Kôdêhîm (טַרְתִּחְוָה קַוְדֶה, law of the priests), Sêpher Kôdêhîm (םְפָר קַוְדֶה, book of the priests), and Sêpher Korâhîm (םְפָר קָוָה, book of offerings). As a descriptive title Leviticus, "the Levitical book," is not inappropriate to the contents of the book, which exhibits an important system of sacrificial worship. In this connexion, however, the term "Levitical" is used in a perfectly general sense, since there is no reference in the book itself to the Levites or their institutions.

The book of Leviticus presents a marked contrast to the two preceding books of the Hexateuch in that it is derived from one document only, viz., the Priestly Code (P), and contains no trace of the other documents from which the Hexateuch has been compiled. Hence the dominant interest is a priestly one, while the contents are almost entirely legislative as opposed to historical.

But though the book as a whole is assigned to a single document, its contents are by no means homogeneous: in fact, the critical problem presented by the legislative portions of Leviticus, though more limited in scope, is very similar to that of the other books of the Hexateuch. Here, too, the occurrence of repetitions and divergencies, the variations of standpoint and practice, and, at times, the linguistic peculiarities point no less clearly to diversity of origin.

The historical narrative, with which P connects his account of the history of the Israelites, is restricted to that period of the Israelites in which they had not suffered the destruction of the Temple. The fourfold division of offerings corresponding to the rank of the offender, (3) is quite capable of being distinguished from sin offering (vv. 6, 7), his guilt-offering (v. 8, 9) contains the sense of the solemn consecration of the priest, by which we read הַלְוָיָה "his oblation" in each case; cf. v. 11, iv. 21. Verses 7-13, on the other hand, form a suitable continuation of iv., though probably they are secondary in character. Chap. 14 presents a priestly legislation, seemingly introduced at a later period compared with Exod. xxiii, Lev. vii. ix.). Chap. v. 1-13 have usually been regarded as an appendix to iv., setting forth (a) a number of typical cases for which a sin-offering is required (v. 1-6), and (b) certain consequences for those who, who could not afford the expense (v. 7-13). But vv. 1-6, which are not homogeneous (vv. 2 and 3 treating of another question and interrupting iv. 1, 4, 5 f.), cannot be ascribed to the same author as iv.; for (1) it presents a different historical viewpoint, and (2) the sin-offering, though it is more than once employed in the new context (v. 5, 6, 7). The idea of the sin-offering is thus introduced as (2) in the middle section (vv. 1-8), which presents the regulations for the priest, in the case of which the distinctive character of that offering is clearly brought out. The cases cited in iv. 1-7 (Heb. v. 20-26) are clearly analogous to those in v. 14-16, from which they are at present separated by v. 8-10. These latter pass a priestly offering for two cases, the same case for which in iv. 22, if a sin-offering is required: it is noticeable also that no restitution, the characteristic feature of the ḥašām, is prescribed. It is hardly doubtful that these verses are derived from a different source to that of their immediate context, possibly the same vv 1-6. The subscription (vii. 37, 38) is our chief guide to determining the original extent of the second group of laws (vii. 8 [Heb. vi. 7]-vii. 36). From it we infer that originally the collection only dealt with the five chief sacrifices (vv. 8; 13-14; 24, 25, 27-30; vii. 1-6; 11-21), already discussed in iv.-v., since only these are referred to in the edification where they are given in the same order (the consecration-offering is put first). The idea of the sin-offering is introduced in the gloss "in the day when he is anointed," in v. 20. Of the remaining sections vii. 19-23 (Heb. 12-16), the daily meal-offering (of the high priest), is secondary origin by its absence from the work of the priests (cf. vii. 18). The daily meal-offering (vii. 26 [Heb. 19]) and vii. 7 assigns the offering to the officiating priest in contrast to vii. 18 (Heb. 11), 29 (Heb. 22), vii. 6 ("every male among the priests"), and possibly belongs, together with vii. 8-10, to a separate collection which dealt especially with priestly dues. Chap. vii. 22-27, which prohibit the eating of fat and blood, are addressed to the community at large, and were, doubtless, inserted here in connexion with the sacrificial meal which formed
the usual accompaniment of the peace-offering. Chap. vii. 28-34 are also addressed to the people, and cannot therefore have formed part of the original priestly manual; v. 33 betrays the same hand as vi. 26 (Heb. 19) and vii. 7, and with 35a may be assigned to the same collection. It is therefore necessary to make v. 32 (a doublet of v. 33) 34, 35b and 36.

Chaps. viii.-x. As stated, these chapters form the original sequel to Exod. xl. They describe (a) the consecration of Aaron and his sons, a chief event of the day (on the eighth day, at which the sacrifice of the first fruit had been offered); (b) the inauguration of the tabernacle on the eighth day, at which Aaron and his sons officiated for the first time as priests (ix.); then follow (c) an account of the death of Nadab and Abihu for offering strange fire (x. 1-5); (d) various regulations for the priests (x. 6-20); (e) an explanation, in narrative form, of the departure in x. 15 from the rules for the sin-offering given in 30 (v. 16-20).

According to Exod. xl. 1-15 Moses was commanded to set up the Tabernacle and to consecrate the priests. The events of the succeeding days (16-18) describe how the former command was carried out. The execution of the second command, however, is first described in Lev. viii., and since the intervening chapters exhibit obvious traces of foreign composition, it is assumed that Lev. viii. formed the immediate continuation of Exod. xl. in the original narrative of P. But it has already been pointed out (see Exodus) that Exod. xxxv.-xl. belong to a later stratum of P, and it is, therefore, probable that Lev. viii.-xiv. have superseded an earlier and shorter account of the fulfilment of the commandments in Exod. xxv.-xxix.

If this be the case, we should naturally expect to find that Lev. viii., which bears the same relation to Exod. xxix. 1-35 as Exod. xxxv. ff. to Exod. xxix. 35-46 (though v. 2 v. 11, the anointing of the altar and the laver were obviously both from the way in which they interrupt the context and also from their contents, are (1), v. 10, the anointing of the Tabernacle in accordance with Exod. xxxv. 26 ff: it is not enjoined in Exod. xxvii. 1 ff.), only mentions one altar, and that in its present form the chapter exhibits marks of later authorship, these marks form no part of the original account, but are clearly the work of a later editor, and characterize the document which has been copied into the present form. The account of the consecration of Aaron and his sons consists of (a) the offerings for Aaron, and (b) those for the congregation; (c) the offering of the first fruit; (d) the consecration of Aaron and his sons; (e) the consecration of the altar. It is evident that the present arrangement is an attempt to represent the story as it happened, as far as possible, and to follow the last two verses, which are identical with those of Chapter vii. 26 ff. The second passage, 9, 9, which prohibits the use of wine and strong drink to the priest when on duty, is added later, and the connexion between these verses and the preceding ones is entirely different (cf. xii. 47), the latter verses must be regarded as a clear example of a later addition. Verses 12-15 relate to the portions of the meal- and peace-offerings which fell to the lot of the priests, and correspond, therefore, with chap. ix. 4: possibly they were wrongly transferred from that chapter. In the remaining part of the chapter, x. 16-20, we have an interesting example of the later type of additions to the Hexateuch. According to x. 15 (cf. n. 11) the priests had burnt the flesh of the offering which had been offered on the altar, and have thereforeinated the altar, 16, 17, was in direct contradiction to the ritual of vi. 24., which states that the flesh of the offering, together with its entrails, was to be burnt. This breach of a ritual on the part of Aaron and his sons seemed to a later editor to demand an explanation, and this is furnished in the present section.

11. The Laws of Purification.... Chaps. xi.-xxvi. This collection of laws comprises four main sections relating to (1) clean and unclean beasts (xli), (2) childbirth (xlii.), (3) leprosy (xliii., iv.), and (4) certain natural sectioons (xv.). These laws, or theâ€”are so closely allied to each other by the nature of their contents and their literary form (cf. especially the recurring formula "This is the law of..."); the sequence is "the eleven days after the first day, and the eleventh day they must again have been offered a single collection. The collection however, has clearly undergone more than one redaction before reaching its final form. This is made evident not only by the present position of chap. xii., which in v. p. presupposes the existence of a similar document to xiv. 1-7, as well as the addition of this last chapter, but also by the contents of the different sections, which exhibit clear traces of repeated revision. At the same time it seems, like chaps. i.-vii., xvii.-xxvi., to have been formed independently of P and to have been added to that document by a later editor; for in its present position it interrupts the main thread of P's narrative, chap. xvi., forming the natural continuation of chap. x.; and, further, the inclusion of Aaron as well as Moses in the formula of address (xi. 1, xiii. 1, xiv. 33, xv. 1) is contrary to the usage of P.
The multiplication of sacrifices and the minute regulations with regard to the blood and oil. The succeeding section (xxviii. 32—xxx.) enjoins special modifications for those who cannot afford the more costly offerings of xxviii. 9-20, and like v. 7-13, xlii. 8 is clearly a later addition; there is a very close connexion between the two, and the whole is closely alluded to xlii. 47-59, though probably later in date: the concluding verses (48-53), in which the same rites are prescribed for the purification of a house as are ordained for a person in chap. xliii. 1-11, are probably an independent expansion.

Chap. xlii. deals with the rites of purification rendered necessary by various natural occurrences, and is therefore closely related to chap. xlii. On the analogy of the other laws it is probable that the last chapter forms the basis of the chaps. as has been already shown. The regulations have been subsequently expanded, but except in the colophon (xxvi. 32-33), which displays marks of later redaction, there is nothing to guide us in separating the additional matter.

Chap. xliii. verse 10 as certain that this chapter consists of three main elements only one of which was originally connected with the ceremonial of the Day of Atonement, and that it has passed through more than one stage of revision. Since the acceptance of Benzing's (2) analysis, certain criticisms in the main have accepted the division of the chapter into three independent sections: (1) vv. 1-4. 6, 12, 13, 34ff. (probably vv. 23, 24 also form part of this section); regulations to be observed by Aaron whenever he might enter the holy place within the veil. These regulations are to be natural outcomes of the deposition of Nadab and Abihu (x. 1-5), and their object is to guard Aaron from a similar fate; the section thus forms the direct continuation of chap. x. (2) vv. 29-34a, rules for the observance of a yearly festival for the purification of the sanctuary and of the people; (3) vv. 5, 7-10, 14-22, a later expansion of the blood ritual to be performed by the high-priest when he enters the Holy of Holies, with which is connected the strange ceremony of the gift of the firstfruits, etc. The connexion of the latter with the former and with the sacrifice of x. 29-34a, is to be primarily considered; the second section belongs to a later stage of development and was added at a later date by (a) the incongruity of vv. 14ff. with vv. 6-9; (b) according to the latter the purification of Aaron is a preliminary condition to the entrance in the Holy of Holies; (c) undoubtedly the regulations in connexion with the sprinkling of the blood. The first section, doubtless, belongs to the main narrative of P; it connects directly with chap. x. and presupposes only one altar (cf. v. 12. Exod. xxviii. 1-10). The second and third sections, however, must be assigned to the later stratum of P, if only because they appear to have been unknown to Ezra (Neh. ix. 1); the fact that Ezra's fast day took place on the twenty-fourth day of the seventh month (as opposed to Lev. xvi. 29ff. and xxviii. 1-10) is an absolute argument against a date to the time of Ezra for these laws, while the regulations of Neh. ix. 1 into an annual ceremony: in any case directions as to the annual performance of the rite must originally have preceded vv. 29f. Possibly the omission of this introduction is due to the re-former's wish to combine (a) many of the words and phrases occurring rarely, if ever, in P (for a list of characteristic phrases cf. Driver, L.O.T., p.49). Further, the structure of these chapters, which closely resembles that of the other two Hexateuchal codes (Exod. xx. 22-xxiii. and Deut. xix.-xxviii.), may reasonably be adduced in support of their independent origin. All three codes contain a somewhat miscellaneous collection of laws; all alike commence with regulations as to the place of sacrifice and close with an exhortation. Lastly, some of the laws treat of subjects which have been already dealt with in Deut. 10-14 and vii. 6 ff. (Lev. xvi. 6-8 and xvii. 15-18).

It is hardly to be doubted that the group of laws, which form the basis of the chaps. xvi.—xxvii., besides being independent of P, represent an earlier stage of legislation than that of Deut. For the sacrificial system in Deut. xxii. 17 and Lev. xvi. 24ff. is not generally paralleled in the Codes, and in particular shows no knowledge of the sin- and trespass-offerings; the high priest is only primus inter pares among his brethren, xvi. 10 (cf. Lev. x. 6, where the same prohibition is extolled to all the priests). It is possible that the regulations of xvi. 10-16, as the original body of xvi. 10-16, of which xvi. 10-16 is a later addition. It cannot be denied, however, that the chaps. xvi.—xxvii. present many points of resemblance with P, both in language and thought. But those points of agreement which are not due to contact are seen to be easily separable from the main body of the legislation. It is highly probable, therefore, that these marks of P are to be assigned to the compiler who combined H with P. But though it may be regarded as certain that H existed as an independent code, it cannot be maintained that the laws which it contains are all of the same origin or belong to the same age. The evidence rather shows that they were first collected by an editor before they were incorporated in P. Thus there is a marked difference in style between the laws themselves and the paraenetic setting in which they are embedded; and it is not unnatural to conjecture that this setting is the work of the first editor.

The connexion with H are of considerable importance: (a) the possibility of other remains of H, and (b) its relation to Deuteronomy and Ezekiel.

(a) It is generally recognized that H, in its present form, is considerably compiled from H. It is therefore possible that other subjects now passed over in silence. These, however, were compiled by the compiler of P, because they had already been dealt with elsewhere, or they may have been transferred to other compositions. Several scholars, who have accordingly claimed many other passages of P as parts of H. We have already accepted xi. 34 ff. as an undoubted excerpt from H, but, with the exception of Num. xxi. 37—41 (on which see xxvii. 35), it is probable that all passages of P attributed to H do not furnish sufficient evidence to justify us in assigning them to that collection. (b) The exact relation of H to Deuteronomy and Ezekiel is hard to determine. Like Deuteronomy, Ezekiel cannot be denied. Like D, they lay great stress on the duties of humanity and charity both to the Israelite and to the stranger (Deut. xxiii.; Lev. xix.); compare also laws affecting the status of the land and the people of H, e.g., xxiii. 21-25. H appears to reflect a more advanced stage than that of D, e.g., the rules for the priesthood (chap. xxiii.), the feasts (xxiii. 9-20, 39-43), the Sabbatical year (xxiv. 17-22), weights and measures (xxv. 35). Laws of H must, therefore, have been passed through more than one stage of revision and that the original regulations have been much obscured by later glosses and additions; it is therefore somewhat hazardous to base any argument on their present form. The mutual independence of the two (e.g., xxxvi. 10 is almost solitary in its unwarranted assumption that all the fragments of Israelite legislation which have been preserved lie in one serial development (Moore, Ency. Bibl. col. 2790). The legislation of H is remarkably close, the resemblances between the two being so striking that many writers have regarded Ezekiel as the author of H. Such a theory, however, is excluded by the existence of even greater differences of style and matter, so that it must be postulated that Ezekiel is no later than P, or even prior to H or vice versa. The main arguments brought forward by those who maintain the priority of Ezekiel are (1) the fact that H makes mention of a high priest, whereas Ezekiel betrays no knowledge of such a person; and (2) the fact that Ezekiel ascribes a condition of exile and looks forward to a restoration from it. Too much weight, however, must not be attached to these points; for (1) the phrase used in Lev. xxi. 10 literally, "he who is greater than I," and the phrase used in Ezek. xlvii. 21 literally, "the chief priest of P, and is rather comparable with the usage of 2 Kings xxii. 4 ff. xxiv. 18 ("the chief priest"). (2) The "priest" in xl. 9 ff. xvi. 10 ff.; (2) the phrase used in xxvi. 10 of the idea of the "chief priest" is, as pointed out by the editor, a translation of the original Hebrew, which, as the editor, states, is not a significant point in the stand-points of the writer, are just those which, on other grounds, show signs of later interpolation. The following considerations undoubtedly suggest the priority of H: (1) there is no trace in H of the distinction between priests and Levites first introduced by Ezekiel; (2) Ezekiel xviii. xxvi. xxvi. appears to presuppose the laws of Leviticus.
Lev. xviii.-xx.; (3) the calendar of Lev. xxi.ii. represents an earlier stage of development than the fixed days and months of Ezek. xiv.; (4) the meal and trespass-offerings are not mentioned in H (cf. Ezek. xli.); (5) H, according to the statement of R, was told to H. These points are found especially in Lev. xvi., xix., xx., i., include both the parameters setting the laws and the laws; and lastly, (6) a comparison of Lev. xxvii., with its two stages of development, shows that the earlier stage is clearly later than Ezekiel, while the second is the main in the prior to that author. The arguments which he adduces in favour of the three stages are not sufficient to outweigh the general impression of unity which the code presents.

Chap. xxiii. comprises four main sections which are clearly marked off by similar introductory and closing formulae: (1) vv. 1-3. Prohibitions of the eating of domestic animals, under the rubric "sacrifice," presented to Yahweh; (2) v. 8, 9, sacrifices to be offered to Yahweh; (3) vv. 10-12, the prohibition of the eating of blood; (4) v. 13, 14, the blood of animals not used in sacrifice to be poured on the ground. The chapter as a whole is to be assigned to the second part of the Pentateuch ("Ye shall be holy." The various laws are clearly defined by the formula "I am Yahweh, or "I am Yahweh your God," phrases which are especially characteristic of chaps. xviii.-x. The first group of the two main laws of the deaconage, while vv. 11-18 are analogous to the second table; vv. 5-8 (on peace-offerings) are obviously out of place here, and are possibly to be regarded as an interpolation. The tabernacle provisions of v. 9 and 10 (cf. xxii. 21, 22) have no connexion with the immediate context; similarly v. 20 (to which a later redactor has added v. 21, 22, in accordance with vi. 6.) appears to belong to a different part of the chapter, and has possibly been introduced from xx. 2-5, the chapter itself changes the art of the chapter, and is a comparison of the laws concerning miscellaneous laws, partly moral, partly religious, of which the fundamental principle is stated in v. 3, "Ye shall be holy." These laws are clearly defined by the formula "I am Yahweh, or "I am Yahweh your God," phrases which are especially characteristic of chapters xviii.-xx. It differs from that chapter, however, in prescribing the death penalty in each case for disobedience. Owing to the close resemblance between the two chapters, many critics have assumed that they are derived from the same source and that the latter chapter was added for the purpose of supplying the penalties. This view, however, is not borne out by a comparison of the two chapters, for four of the cases mentioned in chap. xxi. (vv. 7, 10, 17, 18) are ignored in chap. xx., while the order of the laws is somewhat different; it is difficult on this view to explain why the two chapters are separated by chap. xx. A more probable explanation is that the compiler of H has preserved two parallel, but independent, sources. Signs of revision are not lacking, especially in re-2-5, where they have added later intention to reconcile the incoherency of v. 2 with v. 3 (Rv. v. 6, which is closely connected with xix. 31, appears to be lexicographical, and has been added to the same hand as v. 3; v. 9 can hardly be in its original context; it is, however, suitable after xxvii. 15). The paraenetic setting (v. 7-8 and 22-24) is to be assigned to the compiler of H, who doubtless predated the parallelism of the Laws of Holiness (cf. 4-6). Verses 25-26 apparently formed the conclusion of a law on clean and unclean animals similar to that of chap. xx., and very probably mark the place where H's regulations on that subject originally stood.

Chap. xxiv. comprises laws of the priests and offerings, viz. (1) regulations respecting the holiness of (a) ordinary priests, xx. 1-9, and (b) the chief priest, vv. 10-15; (2) a list of physical defects which exclude a priest from exercising his office, vv. 16-24; (3) the enjoyment of sacred offerings limited to (a) priests, if they are ceremonially clean, xxi. 1-9, and (b) members of a priestly family, vv. 10-16; (4) animals offered in sacrifice must not be blemished, xvii. 25; (f) further regulations with regard to sacrifices, xxvii. 26-30, which are found especially in Ezek. xxxvii., xxxix. 1, include both the parameters setting the laws and the laws; and lastly, (6) a comparison of Lev. xxvii., with its two stages of development, shows that the earlier stage is clearly later than Ezekiel, while the second is the main in the prior to that author. The arguments which he adduces in favour of the three stages are not sufficient to outweigh the general impression of unity which the code presents.

These chapters present considerable difficulty to the literary critic; for while they clearly illustrate the application of the principle of the law to the case, the character of the phenomena is such that it is not clear which process of exegesis is involved. The nature of the laws with which they deal is one that naturally appealed to the priestly school, and owing to this fact the laws were especially liable to modification and expansion. The compiler has been studied to bring them into conformity with later usage. Signs of such revision may be traced back to the compiler of H, but the evidence shows that the process must have been continued down to the latest stages of editing. These phenomena may be best explained by the hypothesis that the compiler of H is the same as the compiler of Ezekiel, and that the later strata of P, which have been closely interwoven into the original laws. These phenomena may be best explained by the hypothesis that the compiler of H is the same as the compiler of Ezekiel, and that the later strata of P, which have been closely interwoven into the original laws. These phenomena may be best explained by the hypothesis that the compiler of H is the same as the compiler of Ezekiel, and that the later strata of P, which have been closely interwoven into the original laws.
underlying the regulations for the year of Jubilee was originally extended to persons in the earlier code. For it is difficult to harmonize the laws as to the release of Hebrew slaves with the other legislation on the same subject (Exod. xxi. 2-6; Deut. xv.), while both points of position which they occupy in this chapter and the more elaborate and formal character point to a later origin for vv. 35-55. Hence these verses in the main must be assigned to Rv. In this connection it is noticeable that vv. 35-38, 39-40, 43: 47, 53, 55, which show the characteristic marks of H, bear no special relation to the Jubilee law, or more generally to the moral-treatment of those Israelites who are compelled by circumstances to sell themselves either to their brethren or to strangers. It is probable, therefore, that they form no part of the original legislation of the year of Jubilee, but have been incorporated in the same pericope. The present form of vv. 24-34 is largely due to Rv, who has certainly added vv. 32-34 (cities of the Levites) and probably vv. 29-31.

Chap. xxvi. The concluding exhortation. After reiterating commands for the observance of holy days and to observe them strictly, chap. i. 12, the chapter sets forth (a) the rewards of obedience, vv. 3-13, and (b) the penalties incurred by disobedience to the preceding laws, vv. 14-16. The discourse, which is spoken throughout in the name of Yahweh, is similar in character to Exod. xxviii. 20-33 and Deut. xvii., more especially to the latter. That it forms an integral part of H is shown both by the recurrence of the same distinctive phraseology and by the emphasis laid on the same motives. At the same time it is hardly doubtful that the original discourse has been considerably modified by the hand of the priestly redactor, especially in the concluding eluding passages. Thus vv. 34, 35, which refer back to xxv. 2 ff., interrupt the connexion and must be assigned to the priestly redactor, while vv. 40-45 display obvious signs of interpolation. With regard to the authenticity of this chapter, it is admitted that Ezekiel presents many striking parallels, and in particular makes use, in common with chap. xxvi., of several expressions which do not occur elsewhere in the Old Testament. But there are also points of difference both as regards phraseology and subject-matter, and in view of these latter it is impossible to hold that Ezekiel was either the author or compiler of this chapter. 

Chap. xxviii. On the commutation of vows and tithes. The chapter as a whole must be assigned to the later strata of H, while vv. 2-25 (on vows) presuppose the year of Jubilee, the section on tithes, vv. 30-33, marks a later stage of development than Num. xviii. 21 ff. (P); vv. 26-29 (on firstlings and devoted things) are supplementary to vv. 2-25, etc.

Literature.—Commentaries: Dillmann-Russel Die Bücher Exodus and Leviticus (1897); Driver and White, SBOT, Leviticus (English, 1898); B. Baetsch, Exod. Lev. v. Num. (1900); Bertholet, Leviticus (KH, 1901). On Leviticus: The Introductions to the Old Testament must be assigned to the later strata of H, while xxv. 2-25 (on vows) presuppose the year of Jubilee, the section on tithes, vv. 30-33, marks a later stage of development than Num. xviii. 21 ff. (P); vv. 26-29 (on firstlings and devoted things) are supplementary to xxv. 2-25, etc.

LEVY, A.—LEWANICA

He wrote Structures et classification des roches éruptives (1889), but his more elaborate studies were carried on with F. Fouqué. Together they wrote on the artificial production of felspar, nepheline and other minerals, and also of meteorites, and produced Mineralogie micrographique (1879) and Synthèse des minéraux et des roches (1882). Levy also collaborated with A. Lacroix in Les Minéraux des roches (1888) and Tableau des minéraux des roches (1888).

LEVY (Fr. leule, from lever, Lat. levare, to lift, raise), the raising of money by the collection of an assessment, &c., a tax or compulsory contribution; also the collection of a body of men for military or other purposes. When all the able-bodied men of a nation are enrolled for service, the French term levée en masse, levy in mass, is frequently used.

LEWALD, FANNY (1811-1888), German author, was born at Königsberg in East Prussia on the 24th of March 1811, of Jewish parentage. When seventeen years of age she embraced Christianity, and after travelling in Germany, France and Italy, settled in 1843 at Berlin. Here, in 1854, she married the author, Adolf Wilhelm Theodor Stahr (1805-1876), and removed after his death in 1886 to Dresden, where she resided, engaged in literary work, until her death on the 5th of August 1886. Fanny Lewald is less remarkable for her writings, which are mostly sober, matter-of-fact works, though displaying considerable talent and culture, than for her championship of “women’s rights,” a question which she was practically the first German woman to take up, and for her scathing satire on the sentimentalism of the Gräfin Hahn Hahn. This authoress she ruthlessly attacked in the exquisite parody (Diogen, Roman von Iwdna Gréßen II . . . . . . . . . . (2nd ed., 1847). Among the best known of her novels are Klementine (1842); Prinz Louis Ferdinand (1849; 2nd ed., 1859); Das Mädchen von Hela (1860); Von Geschlecht zu Geschlecht (8 vols., 1863-1865); Benvenuto (1873), and Stella (1883; English by B. Marshall, 1884). Of her writings in defence of the emancipation of women Osterbrie für die Frauen (1868) and Für und wider die Frauen (1870) are conspicuous. Her autobiography, Meine Lebensgeschichte (6 vols., 1861-1862), is briefly written and affords interesting glimpses of the literary life of her time.

A selection of her works was published under the title Gesammelte Schriften in 12 vols. (1870-1874). Cf. K. Frenzel, Erinnerungen (1889).

LEWANICA (c. 1860—), paramount chief of the Barotse and subject tribes occupying the greater part of the upper Zambezi basin, was the twenty-second of a long line of rulers, whose founder invaded the Barotse valley about the beginning of the 17th century, and according to tradition was the son of a woman named Buya Mambo by a god. The graves of successive ruling chiefs are to this day respected and objects of pilgrimage for purposes of ancestor worship. Lewanika was born on the upper Kabompo in troublous times, where his father—Letia, a son of a former ruler—lived in exile during the interregnum of a foreign dynasty (Makololo), which remained in possession from about 1830 to 1865, when the Makololo were practically exterminated in a night by a well-organized revolt. One of the master intellects of the Barotse nation, he invited Nyanza, a nephew, to rule over them. Eleven years of brutality and licence resulted in the tyrant’s expulsion and subsequent assassination, his place being taken by Ngwana-Wina, a nephew. Within a year abuse of power brought about this chief’s downfall (1877), and he was succeeded by Lobosi, who assumed the name of Lewanika in 1885. The early years of his reign were also stained by many acts of blood, until in 1884 the torture and murder of his own brother led to open rebellion, and it was only through extreme presence of mind that the chief escaped with his life into exile. His cousin, Akufuna or Tatela, was then proclaimed chief. It was during this brief reign that François Coillard, the eminent missionary, arrived at Lialui, the capital. The following year Lewanika, having collected his partisans, deposed the usurper and re-established his power. Ruthless revenge not unmixed with treachery characterized his return to power, but gradually the strong
LEWES, C. L.—LEWES, G. H.

personality of the high-minded François Coillard so far influenced him for good that from about 1857 onward he ruled tolerantly and showed a consistent desire to benefit the condition of his people. The same was with Lewanika, who two years previously had proposed to place himself under the protection of Great Britain, concluded a treaty with the British South Africa Company, acknowledging its supremacy and conceding to it certain mineral rights. In 1897 Mr R. T. Coryndon took up his position at Lialui as British agent, and the country to the east of 25° E. was thrown open to settlers, that to the west being reserved to the Barotse chief. In 1905 the king of Italy’s award in the Barotse boundary dispute with Portugal deprived Lewanika of half of his dominions, much of which had been ruled by his ancestors for many generations. In 1902 Lewanika attended the coronation of Edward VII, as a guest of the nation. His recognized heir was his eldest son Letia.

See BAROTSE, and the works there cited, especially On the Threshold of Central Africa (London, 1897), by François Coillard (A. St. H. G.)

LEWES, CHARLES LEE (1740-1804), English actor, was the son of a hosier in London. After attending a school at Ambleside he went to London, where he found employment as a postman; but about 1760 he went on the stage in the provinces, and some three years later began to appear in minor parts at Covent Garden Theatre. His first rôle of importance was that of "Young Marlow" in She Stoops to Conquer, at its production of that comedy in 1773, when he delivered an epilogue specially written for him by Goldsmith. He remained a member of the Covent Garden company till 1783, appearing in many parts, among which were "Fag" in The Rivals, which he "created," and "Sir Anthony Absolute" in the same comedy. In 1783 he removed to Drury Lane, where he assumed the Shakespearean rôles of "Touchstone," "Lucio," and "Falstaff." In 1787 he left London for Edinburgh, where he gave recitations, including Cowper’s "John Gilpin." For a short time in 1792 Lewes assisted Stephen Kemble in the management of the Drury Lane Theatre; in the following year he went to Dublin, but he was financially unsuccessful and suffered imprisonment for debt. He employed his time in compiling his Memoirs, a worthless production published after his death by his son. He was also the author of some poor dramatic sketches. Lewes died on the 23rd of July 1803. He was three times married; the philosopher, George Henry Lewes, was his grandson.

See John Genest, Some Account of the English Stage (Bath, 1832).

LEWES, GEORGE HENRY (1817-1878), British philosopher and literary critic, was born in London in 1817. He was a grandson of Charles Lee Lewes, the actor. He was educated in London, Jersey, Brittany, and finally at Dr Burney’s school in Greenwich. Having abandoned successively a commercial and a medical career, he seriously thought of becoming an actor, and between 1831 and 1836 appeared several times on the stage. Finally he devoted himself to literature, science and philosophy. As early as 1836 he belonged to a club formed for the study of philosophy, and had sketched out a physiological treatment of the philosophy of the Scottish school. Two years later he went to Germany, probably with the intention of studying philosophy. In 1840 he married a daughter of the Rev. Stephen Lewes (1785-1873), and during the next ten years supported himself by contributing to the quarterly and other reviews. These articles discuss a wide variety of subject, and, though often characterized by hasty impulse and imperfect study, betray a singularly acute critical judgment, enlightened by philosophic study. The most valuable are those on the drama, afterwards republished under the title Actors and Acting (1875). With this may be taken the volume on The Spanish Drama (1846). The combination of wide scholarship, philosophic culture and practical acquaintance with the theatre gives these essays a high place among the best efforts in English dramatic criticism. In 1845-1846 he published The Biographical History of Philosophy, an attempt to depict the life of philosophers as an ever-renewed fruitless labour to attain the unattainable. In 1847-1848 he made two attempts in the field of fiction—Ran thrope, and Rose, Blanche and Violet—which, though displaying considerable skill both in plot, construction and characterization, have taken no permanent place in literature. The same is to be said of an ingenious attempt to rehabilitate Robespierre (1849). In 1850 he collaborated with Thornton Leigh Hunt in the foundation of the Leader, of which he was the literary editor. In 1853 he republished under the title of Comte’s Philosophy of the Sciences a series of papers which had appeared in that journal. In 1851 he became acquainted with Miss Evans (George Elliot) and in 1854 left his wife. Subsequently he lived with Miss Evans as her husband (see Elliot, George).

The culmination of Lewes’s work in prose literature is the Life of Goethe (1853), probably the best known of his writings. Lewes’s many-sidedness of mind, and his combination of scientific with literary tastes, eminently fitted him to appreciate the large nature and the wide-ranging activity of the German poet. The high position this work has taken in Germany itself, notwithstanding the boldness of its criticism and the unpopularity of some of its views (e.g. on the relation of the second to the first part of Faust), is a sufficient testimony to its general excellence. From about 1853 Lewes’s writings showed that he was occupying himself with scientific and more particularly biological work. He may be said to have always manifested a distinctly scientific bent in his writings, and his closer devotion to science was but the following out of early impulses. Considering that he had not had the usual course of technical training, these studies are a remarkable testimony to the penetration of his intellect. The most important of these essays are collected in the volumes Seaside Studies (1858), Physiology of Common Life (1859), Studies in Animal Life (1862), and Aristotle, a Chapter from the History of Science (1864). They are much more than popular expositions of accepted scientific truths. They contain able criticisms of authorized ideas, and embody the results of individual research and individual reflection. He made a number of impressive suggestions, some of which have since been accepted by physiologists. Of these the most valuable is that now known as the doctrine of the functional indifferentials of the nerves—those specific energies of the optic, auditory and other nerves are simply differences in their mode of action due to the differences of the peripheral structures or sense-organs with which they are connected. This idea was subsequently arrived at independently by Wundt (Physiologische Psychologie, 2nd ed., p. 321). In 1865, on the starting of the Fortnightly Review, Lewes became its editor, but he retained the post for less than two years, when he was succeeded by John Morley. This date marks the transition from more strictly scientific to philosophic work. He had from early youth cherished a strong liking for philosophic studies; one of his earliest essays was an appreciative account of Hegel’s Ästhetics. Coming under the influence of positivism as unfolded both in Comte’s own works and in J. S. Mill’s System of Logic, he abandoned all faith in the possibility of metaphysic, and recorded this abandonment in the above-mentioned History of Philosophy. Yet he did not at any time give an unqualified adhesion to Comte’s teachings, and with wider reading and reflection he maintained away from the positivist standpoint. In the preface to the third edition of his History of Philosophy he avowed a change in this direction, and this movement is still more plainly discernible in subsequent editions of the work. The final outcome of this intellectual progress is given to us in The Problems of Life and Mind, which may be regarded as the crowning work of his life. His sudden death on the 28th of November 1878 cut short the work, yet it is complete enough to allow us to judge of the author’s matured conceptions on biological, psychological and metaphysical problems. Of his three sons only one, Charles (1843-1861), survived him; in the first London County Council Election (1888) he was elected for St Pancras; he was also much interested in the Hampstead Heath extension.

Philosophy.—The first two volumes on The Foundations of a Creed lay down what Lewes regarded as the true principles of philosophizing. He here seeks to effect a rapprochement between metaphysic and science. He is still so far a positivist as to pronounce all inquiry into the ultimate nature of things fruitless. What matter, form, spirit are
in themselves is a futile question that belongs to the sterile region of "meteirnics." But philosophical questions may be so stated as to be susceptible of a precise solution by scientific method. Thus, since the relation of subject to object falls within our experience, it is a proper philosophical method to examine the philosophical question of whether Lewes is right in thus identifying the methods of science and philosophy. Philosophy is not a mere extension of scientific knowledge; it is an investigation of the nature and validity of the knowing process itself. In any case Lewes cannot be said to have answered the question of whether he is the subject or object of philosophical questions. His whole treatment of the question of the relation of subject to object is vitiated by a confusion between the scientific truth that mind and body exist in the living organism and the philosophic truth that knowing and its object are distinct.

In other words, to use Shawdworth Hodgson's phrase, he mixes up the question of the genesis of mental forms with the question of their nature (see Philosophy of Reflection, ii. 40-58). Thus he reaches the same conclusion and makes the same mistake of different aspects of the same existence by attending simply to the parallelism between psychical and physical processes given as a fact (or as a probable fact) of our experience, and by leaving out of account their relation as subject and object in the cognitive act. His identification of the two alternative phases of one existence is open to criticism, not only from the point of view of philosophy, but from that of science. In his treatment of such ideas as "sensibility," "sentience," and the like, he does not always show whether he is speaking of physical or of psychical, of organic or of mechanical, processes. The questions discussed in these two volumes the nature of the casual relation is perhaps the one which is handled with most freshness and suggestiveness. The third volume, The Physical Basis of Mind, further develops his views on organic activity as a whole. He insists strongly on the radical distinction between organic and inorganic processes, and on the impossibility of ever explaining the former by purely mechanical principles. With respect to the nervous system and the brain he advances the same arguments on organic activity as a whole. He insists strongly on the radical distinction between organic and inorganic processes, and on the impossibility of ever explaining the former by purely mechanical principles. With respect to the nervous system and the brain he advances the same arguments on organic activity as a whole.

LEWES, a market-town and municipal borough and the county town of Sussex, England, in the Lewes parliamentary division, 50 m. S. from London by the London, Brighton & South Coast railway. Pop. (1901) 11,249. It is picturesquely situated on the slope of a chalk down falling to the river Ouse. Ruins of the old castle, supposed to have been founded by King Alfred and rebuilt by William de Warrely shortly after the Conquest, rise from the height. There are two mounds which bore keeps, an uncommon feature. The castle guarded the pass through the downs formed by the valley of the Ouse. In one of the towers is the collection of the Sussex Archaeological Society. St Michael's church is without architectural merit, but contains old brasses and monuments; St Anne's church is a transitional Norman structure; St Thomas-at-Cliffe is Perpendicular; St John's, Southover, of mixed architecture, preserves some early Norman portions, and has some relics of the Warenne family. In the grounds of the Cluniac priory of St Pancras, founded in 1278, the leaden coffin of William de Warenne and Gundred his wife were dug up during an excavation for the railway in 1845. There is a grammar school dating from 1512, and among the other public buildings are the town hall and corn exchange, county hall, prison, and the Custom House, and the manufacture of agricultural implements, brewing, tanning, and iron and brass founding. The municipal borough is under a mayor, 6 aldermen and 18 councillors. Area, 1242 acres.

The many neolithic and bronze implements that have been discovered, and the numerous tumuli and earthworks which surround Lewes, indicate its remote origin. The town Lewes (Loewas, Loewen, Leswa, Laquis, Latisaquessin) was in the royal demesne of the Saxon kings, from whom it received the privilege of a market. Æthelstan established two royal mints there, and by the reign of Edward the Confessor, and probably before, Lewes was certainly a borough. William I. granted the whole barony of Lewes, including the revenue arising from the town, to William de Warenne, who converted an already existing fortification into a place of residence. His descendants continued to hold the barony until the beginning of the 14th century. In default of male issue, it then passed to the earl of Arundel, with whose descendants it remained until 1439, when it was divided between the Normans, Dorsets and Abergavennis. By 1886 the borough was sold to the borough of Lewes, the beginning of the reign of the 13th century, and its importance as a port and market-town is evident from Domesday. A guild merchant seems to have existed at an early date. The first mention of it is in a charter of Reginald de Warenne, about 1148, by which he restored to the burgesses the privileges they had enjoyed in the time of his grandfather and father, but of which they had been deprived. In 1593 a "Fellowship" took the place of the old guild and in conjunction with two constables governed the town until the beginning of the 18th century. The borough seal probably dates from the 14th century. Lewes was incorporated by royal charter in 1881.

The town returned two representatives to parliament from 1295 until deprived of one member in 1867. It was disfranchised in 1885. Earl Warenne and his descendants held the fairs and markets from 1066. In 1372 the fair days were the 6th of May, Whit-Tuesday, the 26th of July (for wool), and the 2nd of October. The market-day was Saturday. Fairs are now held on the 6th of May for horses and cattle, the 26th of July for wool, and the 21st and 28th of September for Southdown sheep. A corn-market is held every Tuesday, and a stock-market every Monday. The trade in wool has been important since the 14th century.

Lewes was the scene of the battle fought on the 14th of May 1264 between Henry III. and Simon de Montfort, earl of Leicester. Led by the king and his son, the future king Edward I., the royalists left Oxford, took Northampton and drove Montfort from Rochester into London. Then, harassed on the route by their foes, they marched through Kent into Sussex and took up their quarters at Lewes, a stronghold of the royalist Earl Warenne. Meanwhile, reinforced by a number of Londoners, Earl Simon left London and reached Fletching, about 9 m. north of Lewes,

(J.S.; X.)
on the 13th of May. Efforts at reconciliation having failed he led his army against the town, which he hoped to surprise, early on the following day. His plan was to direct his main attack against the priory of St Pancras, which sheltered the king and his brother Richard, earl of Cornwall, king of the Romans, while causing the enemy to believe that his principal objective was the castle, where Prince Edward was. But the surprise was not complete and the royalists rushed from the town to meet the enemy in the open field. Edward led his followers against the Londoners, who were gathered around the standard of Montfort, put them to flight, pursued them for several miles, and killed a great number of them. Montfort's ruse, however, had been successful. He was not with his standard as his foes thought, but with the pick of his men he attacked Henry's followers and took prisoner both the king and his brother. Before Edward returned from his chase the earl was in possession of the town. In its streets the prince strove to retrieve his fortunes, but in vain. Many of his men perished in the river, but others escaped, one band, consisting of Earl Wareme and others, taking refuge in Pevensive Castle. Edward himself took sanctuary and on the following day peace was made between the king and the earl.

LEWES, a town in Sussex county, Delaware, U.S.A., in the S.E. part of the state, on Delaware Bay. Pop. (1910), 21,586. Lewes is served by the Philadelphia, Baltimore & Washington (Pennsylvania System), and the Maryland, Delaware & Virginia railroads. Its harbour is formed by the Delaware Breakwater, built by the national government and completed in 1866, and 23 m. above it another breakwater was completed in December 1901 by the government. The cove between them forms a harbour of refuge of about 550 acres. At the mouth of Delaware Bay, about 2 m. below Lewes, is the Henlopen Light, one of the oldest lighthouses in America. The Delaware Bay pilots make their headquarters at Lewes. Lewes has a large trade with northern cities in fruits and vegetables, and is a suburb of entry of the Wilmington Customs District. The first settlement on Delaware soil by Europeans was made near here in 1631 by Dutch colonists, sent by a company organized in Holland in the previous year by Samuel Blommaert, Killian von Rensselaer, David Pietersen de Vries and others. The settlers called the place Zwanendael, valley of swans. The settlement was soon entirely destroyed by the Indians, and a second body of settlers whom de Vries, who had been made director of the colony, brought in 1632 remained for only two years. The fact of the settlement is important; because of it the English did not unite the Delaware country with Maryland, for the Maryland Charter of 1632 restricted colonization to land within the prescribed boundaries, uncultivated and either uninhabited or inhabited only by Indians. In 1658 the Dutch established an Indian trading post, and in 1659 erected a fort at Zwanendael. After the annexation of the Delaware counties to Pennsylvania in 1682, its name was changed to Lewes, after the town of that name in Sussex, England. It was pillaged by French pirates in 1688. One of the last naval battles of the War of Independence was fought in the bay near Lewes on the 8th of April 1782, when the American privateer "Hyder Ally" (16), commanded by Captain Joshua Barnes (1759-1818), defeated and captured the British sloop "General Monk" (20), which had been an American privateer, the "General Washington," had been captured by Admiral Arbuthnot's squadron in 1780, and was now purchased by the United States government and, as the "General Washington," was commanded by Captain Barnes in 1782-1784. In March 1813 the town was bombarded by a British frigate.

LEWIS, SIR GEORGE CORNEWALL, Bart. (1806-1863). English statesman and man of letters, was born in London on the 21st of April 1806. His father, Thomas F. Lewis, of Harpton Court, Radnorshire, after holding subordinate office in various administrations, became a poor-law commissioner, and was made a baronet in 1846. Young Lewis was educated at Eton and at Christ Church, Oxford, where in 1828 he took a first-class in classics and a second-class in mathematics. He then entered the Middle Temple, and was called to the bar in 1831. In 1833 he undertook his first public work as one of the commissioners to inquire into the condition of the poor Irish residents in the United Kingdom.1 In 1834 Lord Althorp included him in the commission to inquire into the state of church property and church affairs generally in Ireland. To this fact we owe his work on Local Disturbances in Ireland, and the Irish Church Question (London, 1836), in which he condemned the existing connexion between church and state, proposed a state provision for the Catholic clergy, and maintained the necessity of an efficient workhouse organization. During this period Lewis's mind was much occupied with the study of language. Before leaving college he had published some observations on Whatley's doctrine of the predilecables, and soon afterwards he assisted Thriftwell and Hare in starting the Philological Museum. Its successor, the Classical Museum, he also supported by occasional contributions. In 1835 he published an Essay on the Origin and Formation of the Romance Languages (re-edited in 1862), the first effective criticism in England of Raynouard's theory of a uniform romance tongue, represented by the poetry of the troubadours. He also compiled a glossary of provincial words used in Herefordshire and the adjoining counties. But the most important work of this earlier period was one to which his logical and philological tastes contributed. The Remarks on the Use and Abuse of some Political Terms (London, 1832) may have been suggested by Bentham's Book of Parliamentary Follacies, but it shows all that power of clear sober original thinking which marks his larger and later political works. Moreover, he translated Boeckh's Public Economy of Athens and Müller's History of Greek Literature, and he assisted Tufnell in the translation of Müller's Dorians. Some time afterwards he edited a text of the Fables of Babrius. While his friend Hayward conducted the Law Magazine, he wrote in it frequently on such subjects as secondary punishments and the penitentiary system. In 1836, at the request of Lord Glemelg, he accompanied John Austin to Malta, where they spent nearly two years reporting on the condition of the island and framing a new code of laws. One leading object of both commissioners was to associate the Maltese in the responsible government of the island. On his return to England Lewis succeeded his father as one of the principal poor-law commissioners. In 1841 appeared the Essay on the Government of Dependencies, a systematic statement and discussion of the various relations in which colonies may stand towards the mother country. In 1844 Lewis married Lady Maria Theresa Lister, sister of Lord Clarendon, and a lady of literary tastes. Much of their married life was spent in Knightsbridge, Knightsbridge. They had no children. In 1847 Lewis resigned his office. He was then returned for the county of Hereford, and Lord John Russell appointed him secretary to the Board of Control, but a few months afterwards he became under-secretary to the Home Office. In this capacity he introduced two important bills, one for the abolition of turnpike trusts and the management of highways by a mixed county board, the other for the purpose of defining and regulating the law of parochial assessment. In 1850 he succeeded Hayter as financial secretary to the treasury. About this time, also, appeared his Essay on the Influence of Authority in Matters of Opinion. On the dissolution of parliament which followed the resignation of Lord John Russell's ministry in 1852, Lewis was defeated for Herefordshire and then for Peterborough. Excluded from parliament he accepted the editorship of the Edinburgh Review, and remained editor until 1855. During this period he served on the Oxford commission, and on the commission to inquire into the government of London. But his chief fruits were the Treatise on the Methods of Observation and Reasoning in Politics, and the Enquiry into the Credibility of the Early Roman History,2 in which he vigorously attacked

2 Translated into German by Liebrecht (Hanover, 1898).
LEWIS, H. C.—LEWIS, M.

the theory of epic lays and other theories on which Niebuhr's reconstruction of that history had proceeded. In 1855 Lewis succeeded his father in the baronety. He was at once elected member for the Radnor boroughs, and Lord Palmerston made him chancellor of the exchequer. He had a war loan to contract and heavy additional taxation to impose, but his industry, method and clear vision carried him safely through. After the change of ministry in 1859 Sir George became home secretary under Lord Palmerston, and in 1861, much against his wish, he succeeded Sidney Herbert (Lord Herbert of Lea) at the War Office. The closing years of his life were marked by increasing intellectual vigour. In 1859 he published an able Essay on Foreign Jurisdiction and the Extradition of Criminals, a subject to which the attempt on Napoleon's life, the discussions on the Conspiracy Bill, and the trial of Bernard, had drawn general attention. He advocated the extension of extradition treaties, and condemned the principal idea of Weltrichtsordnung which Mohl of Heidelberg had proposed. His two latest works were the Survey of the Astronomy of the Ancients, in which, without professing any knowledge of Oriental languages, he applied a sceptical analysis to the ambitious Egyptology of Bunsen; and the Dialogue on the Best Form of Government, in which, under the name of Critor, the author points out to the supporters of the various systems that there is no one abstract government which is the best possible for all times and places. An essay on the Characteristics of Federal, National, Provincial and Municipal Government does not seem to have been published.

Sir George died in April 1863. A marble bust by Weekes stands in Westminster Abbey.

Lewis was a man of mild and affectionate disposition, much beloved by a large circle of friends, among whom were Sir E. Head, the Grotes, the Austins, Lord Stanhope, J. S. Mill, Dean Milman, the Duff Gordons. In public life he was distinguished, as Lewis said, for "the love of truth," he had a passion for the systematic acquirement of knowledge, and a keen and sound critical faculty. His name has gone down to history as that of a many-sided man, sound in judgment, unselfish in political life, and abounding in practical good sense.

A reprint from the Edinburgh Review of his long series of papers on the Administration of Great Britain appeared in 1864, and his Letters to various Friends (1870) were edited by his brother Gilbert, who succeeded him in the baronety.

LEWIS, HENRY CARVILL (1835-1888), American geologist, was born in Philadelphia on the 16th of November 1835. Educated in the university of Pennsylvania he took the degree of M.A. in 1856. He became attached to the Geological Survey of Pennsylvania in 1879, serving for three years as a volunteer member, and during this term he became greatly interested in the study of glacial phenomena. In 1880 he was chosen professor of mineralogy in the Philadelphia academy of natural sciences, and in 1883 he was appointed to the chair of geology in Haverford College, Pennsylvania. During the winters of 1885 to 1887 he studied petrology under H. F. Rosenbusch at Heidelberg, and during the summers he investigated the glacial geology of northern Europe and the British Islands. His observations in North America, where he had studied under Professor G. F. Wright, Professor T. C. Chamberlin and Warren Upham, had demonstrated the former extension of land-ice, and the existence of great terminal moraines. In 1884 his Report on the Terminal Moraine in Pennsylvania and New York was published: a work containing much information on the limits of the North American ice-sheet. In Britain he sought to trace in like manner the southern extent of the terminal moraines formed by British ice-sheets, but before his conclusions were matured he died at Manchester on the 21st of July 1888. The results of his observations were published in 1894 entitled Papers and Notes on the Glacial Geology of Great Britain and Ireland, edited by Dr H. W. Crosskey.

LEWIS, JOHN FREDERICK (1805-1876), British painter, son of F. C. Lewis, engraver, was born in London. He was elected in 1827 associate of the Society of Painters in Water Colours, of which he became full member in 1829 and president in 1855; he resigned in 1858, and was made associate of the Royal Academy in 1859 and academician in 1865. Much of his earlier life was spent in Spain, Italy and the East, but he returned to England in 1851 and for the remainder of his career devoted himself almost exclusively to Eastern subjects, which he treated with extraordinary care and minuteness of finish, and with much beauty of technical method. He is represented by a picture, "Edfu: Upper Egypt," in the National Gallery of British Art. He achieved equal eminence in both oil and water-colour painting.

LEWIS, MATTHEW GREGORY (1775-1818), English romance-writer and dramatist, often referred to as "Monk," Lewis, was born in London on the 9th of July 1775. He was educated for a diplomatic career at Westminster school and at Christ Church, Oxford, spending most of his vacations abroad in the study of modern languages; and in 1794 he proceeded to the Hague as attaché to the British embassy. His stay there lasted only a few months, but was marked by the composition, in ten weeks, of his romance Ambrosio, or the Monk, which was published in the summer of the following year. It immediately achieved celebrity; but some passages it contained were of such a nature that about a year after its appearance an injunction to restrain its sale was moved for and a rule nisi obtained. Lewis published a second edition from which he had expunged, as he thought, all the objectionable passages, but the work still remains of such a character as almost to justify the severe language in which Byron in English Bards and Scotch Reviewers addresses—

"Wonder working Lewis, Monk or Bard.
Who fain would make Parnassus a churchyard:
Even Satan's self with thee might dread to dwell,
And in thy skull discern a deeper hell."

Whatever its demerits, ethical or aesthetic, may have been, The Monk did not interfere with the reception of Lewis into the best English society; he was favourably noticed at court, and almost as soon as he came of age he obtained a seat in the House of Commons as member for Hindon, Wilt. After some years, however, during which he never addressed the House, he finally withdrew from a parliamentary career. His tastes lay wholly in the direction of literature, and The Castle Spectre (1796), a musical drama of no great literary merit, but which enjoyed a long popularity on the stage, The Minister (a translation from Schiller's Kabale u. Liebe), Kolla (1797, a translation from Kotzebue), with numerous other operatic and tragic pieces, appeared in rapid succession. The Bravo of Venice, a romance translated from the German, was published in 1804; next to The Monk it is the best known work of Lewis. By the death of his father he succeeded to a large fortune, and in 1815 embarked for the West Indies to visit his estates; in the course of this tour, which lasted four months, the Journal of a West Indian Proprieter, published posthumously in 1833, was written. A second visit to Jamaica was undertaken in 1817, in order that he might become further acquainted with, and able to ameliorate, the condition of the slave population; the fatigue to which he exposed himself in the tropical climate brought on a fever which terminated fatally on the homeward voyage on the 14th of May 1818.

The Life and Correspondence of M. G. Lewis, in two volumes, was published in 1839.

LEWIS, MERIWETHER (1774-1809), American explorer, was born near Charlotteville, Virginia, on the 18th of August 1774. In 1794 he volunteered with the Virginia troops called out to suppress the "Whisky Insurrection," was commissioned as ensign in the regular United States army in 1795, served with distinction under General Anthony Wayne in the campaigns against the Indians, and attained the rank of captain in 1797. From 1801 to 1803 he was the private secretary of President Jefferson. On the 18th of January 1803 Jefferson sent a confidential message to Congress urging the development of trade with the Indians of the Missouri Valley and recommending that an exploring party be sent into this region, notwithstanding
The fact that it was then held by Spain and owned by France. Congress appropriated funds for the expedition, and the president instructed Lewis to proceed to the head-waters of the Missouri river and thence across the mountains to the Pacific Ocean.

When Jefferson's consent Lewis chose as a companion Lieut. William Clark, an old friend and army comrade. The preparations were made under the orders of the War Department, and, until the news arrived that France had sold Louisiana to the United States, they were conducted in secrecy. Lewis spent some time in Philadelphia, gaining additional knowledge of the natural sciences and learning the use of instruments for determining positions; and late in 1803 he and Clark, with twenty-nine men from the army, went into winter quarters near St. Louis, where the men were subjected to rigid training. On the 14th of May 1804 the party, with sixteen additional members, who, however, were to go only a part of the way, started up the Missouri river in three boats, and by the 2nd of November had made the difficult ascent of the stream as far as 47° 21' N. lat., near the site of the present Bismarck, North Dakota, where, among the Mandan Indians, they passed the second winter. Early in April 1805 the ascent of the Missouri was continued as far as the three forks of the river, which were named the Jefferson, the Gallatin and the Madison. The Jefferson was then followed to its source in the south-western part of what is now the state of Montana. Procuring a guide and horses from the Shoshone Indians, the party pushed westward through the Rocky Mountains in September, and on the 7th of October embarked in canoes on a tributary of the Columbia river, the mouth of which they reached on the 15th of November. They had travelled upwards of 4000 m. from their starting point, had encountered various Indian tribes never before seen by whites, had made valuable scientific collections and observations, and were the first explorers to reach the Pacific by crossing the continent north of Mexico. After spending the winter on the Pacific coast they started on the 23rd of March 1806 on their return journey, and, after crossing the divide, Lewis with one party explored Maria's river, and Clark with another the Yellowstone. On the 12th of August the two explorers reunited near the junction of the Yellowstone and the Missouri, and on the 23rd of September reached St. Louis. In spite of exposure, hardship and peril only one member of the party died; and only one deserted. No later feat of exploration, perhaps, in any quarter of the globe has exceeded this in romantic interest. The expedition was commemorated by the Lewis and Clark Centennial Exposition at Portland, Oregon, in 1905. The leaders and men of the exploring party were rewarded with liberal grants of land from the public domain, Lewis receiving 500 acres; and in 1807 the state of Missouri granted members of the immediate party of the territory obtained from France in 1803, which has since been organized as the Louisiana Territory. He performed the duties of this office with great efficiency, but it is said that in the unwonted quiet of his new duties, his mind, always subject to melancholy, became unbalanced, and that while on his way to Washington he committed suicide about 60 m. south-west of Nashville, Tennessee, on the 11th of October 1806. It is not definitely known, however, whether he actually committed suicide or was murdered.

Bibliography.—Jefferson's Message from the President of the United States, Communicating Discoveries made in Exploring the Missouri, Red River and Waskita by Captains Lewis and Clark, Dr. Sibley and Mr. Dunbar (Washington, 1806, and subsequent editions) is the earliest account, containing the reports sent back by the explorers in the winter of 1804-1805. Patrick Gass's Journal of the Voyage of Lewis and Clark, Corps of Discoveries (ed. by C. Merriam, 1885) is an account of a sergeant in the party. Biddle and Allen's History of the Expedition under the Command of Capt. Lewis and Capt. Clark (Pittsburg, 1857) is the account of a participant in the party. Biddle and Allen's History of the Expedition under the Command of Captains Lewis and Clark (2 vols., Philadelphia, 1840) is a full account of the original text. The reprints of this work, the best being that of Elliott Colvett (4 vols., New York, 1893), which contains additions from the original manuscript and a new chapter, in the style of Biddle, inserted as though a part of the original text. As a final authority consult R. C. Thwaites (ed.), The Original Journals of the Lewis and Clark Expedition (8 vols., New York, 1903-1905), containing all the known literary records of the expedition. For popular accounts see W. R.

Lewisburg, a borough and the county-seat of Union county, Pennsylvania, U.S.A., on the W. bank of West Branch of the Susquehanna river, about 50 m. N. of Harrisburg. Pop. (1900) 3457 (60 foreign-born); (1901) 3585. It is served by the University of Lewisburg and the Philadelphia & Reading railways. It is the seat of Bucknell University (coeducational), opened in 1846 as the University of Lewisburg and renamed in 1886 in honour of William Bucknell (1809-1890), a liberal benefactor. The university comprises a College of Liberal Arts, an Academy for Young Men, an Institute for Young Women, and a School of Music, and in 1808-1900 had 50 instructors and 777 students, of whom 54 were in the College of Liberal Arts. The city is situated in a farming region, and has various manufactures, including flour, lumber, furniture, woolens, nails, foundry products and carriages. Lewisburg (until about 1805 called Derrstown) was founded and laid out in 1785 by Ludwig Derr, a German, and was chartered as a borough in 1812.

Lewisham, a southern metropolitan borough of London, England, bounded N.W. by Deptford, N.E. by Greenwich, E. by Woolwich, and W. by Camberwell, and extending S. to the boundary of the county of London. Pop. (1901) 127,405. Its area is for the most part occupied by villas. It includes the districts of Blackheath and Lee in the north, Hither Green, Catford and Brockley in the central parts, and Forest Hill and part of Sydenham in the south-west. In the district last named well-wooded hills rise above 300 ft., and this is an especially favoured residential quarter, its popularity being formerly increased by the presence of medicinal springs, discovered in 1640, on Sydenham Common. Towards the south, in spite of the constant extension of building, there are considerable tracts of ground uncovered, apart from public grounds. In the north the borough includes the greater part of Blackheath (q.v.), an open common of considerable historical interest. The other principal pleasure grounds are Hilly Fields (46 acres) and Ladywell Recreation Grounds (46 acres) in the north-west part of the borough; and at Sydenham (but outside the boundary of the county of London) is the Crystal Palace. Among institutions are the Horniman Museum, Forest Hill (1901); Morden College, on the south of Blackheath, founded at the close of the 17th century by Sir John Morden for Turkey merchants who were received as pensioners, and subsequently extended in scope; numerous schools in the same locality; and the Park Fever Hospital, Hither Green. The parliament for the borough of Lewisham returns one member. The borough council consists of a mayor, 7 aldermen and 42 councillors. Area, 7074.4 acres.

Leiston, a city of Androscoigan county, Maine, U.S.A., on the Androscoigan river, opposite Auburn, with which it is connected by four steel bridges, and about 36 m. N.E. of Portland. Pop. (1900) 23,761, of whom 9316 were foreign-born; (1910) 26,247. It is served by the Maine Central, the Grand Trunk, the Portland & Rumford Falls and the Leiston, Augusta & Waterville (electric) railways. The surrounding country is hilly and the river is picturesque; in the vicinity there are many lakes and ponds abounding in salmon and trout. The Maine fish hatchery is on Lake Auburn, 3 m. above the city. Leiston is the seat of Bates College, a non-sectarian institution, which grew out of the Maine State Seminary (chartered in 1884), and was chartered in 1854 under its present name, adopted in honour of Benjamin E. Bates (d. 1877), a liberal benefactor. In 1808-1810 the college had 25 instructors and 440 students, and its library contained 34,000 volumes. The campus of the college is about 1 m. from the business portion of Leiston and covers 50 acres; among the college buildings are an auditorium (1900) given by W. Scott Libbey of Leiston, and the Libbey Forum for the use of the three literary societies and the two Christian associations of the college. The literary societies give excellent training in forensics. The matriculation pledge requires from male students total abstinence from intoxicants.
as a condition of membership. There are no secret fraternities. From the beginning women have been admitted on the same terms as men. The Cobb Divinity School (Free Baptist), which was founded at Parsonfield, Maine, in 1840 as a department of Parsonfield Seminary, and was situated in 1842–1844 at Dracut, Massachusetts, in 1844–1854 at Whitestown, New York, and in 1854–1870 at New Hampton, New Hampshire, was removed to Lewiston in 1870 and became a department (known as Bates Theological Seminary until 1888) of Bates College, with which it was merged in 1908. Lewiston has a fine city hall, a Carnegie library and a public park of 103 acres, with a bronze soldiers’ monument by Franklin Simmons, who was born in 1830 at Webster near Lewiston, and is known for his statues of Roger Williams, William King, Francis H. Pierpont and U. S. Grant in the national Capitol, and for ‘“Grief’’ and ‘“History’’ on the Peace Monument at Washington. In Lewiston are the Central Maine General Hospital (1888), the Sisters’ Hospital (1888), under the charge of the French Catholic Sisters of Charity, a home for aged women, a young women’s home and the Hesley Asylum for boys. The Shrine Building (Kora Temple), dedicated in 1900, is the headquarters of the Shriners of the state. The river at Lewiston breaks over a ledge of mica-schist and gneiss, the natural fall of 40 ft. having been increased to more than 50 ft. by a strong granite dam; and 3 m. above the city at Deer Rips a cement dam furnishes 10,000 horse-power. The water-power thus obtained is distributed by canals from the nearer dam and transmitted by wire from the upper dam. The manufacture of cotton goods is the principal industry, and in 1905 the product of the state’s cotton mills was valued at about one-third of that of the mills of the whole state. Among other industries are the manufacture of woollen goods, shirts, dry-plates, carriages, spools and bobbins, and boots and shoes, and the dyeing and finishing of textiles. The total factory product in 1905 was valued at $8,537,649. The municipality owns its water works and electric lighting plant. Lewiston was settled in 1770, incorporated as a township in 1795 and charted as a city in 1861. It was the home of Nelson Dingley (1832–1889), who from 1836 until his death controlled the Lewiston Journal. He was governor of the state in 1874–1876, Republican representative in Congress in 1881–1889, and the drafter of the Dingley Tariff Bill (1897).

LEWIS-WITH-HARRIS, the most northerly island of the Outer Hebrides, Scotland. It is sometimes called the Long Island and is 24 m. from the nearest point of the mainland, from which it is separated by the strait called The Minch. It is 60 m. long and has an extreme breadth of 30 m., its average breadth being 15 m. It is divided into two portions by a line running from Cabeg to between Loch Resort on the west and Loch Sannorth on the east, of which the larger or more northerly portion, known as Lewis (pron. Lewis), belongs to the county of Ross and Cromarty and the lesser, known as Harris, to Inverness-shire. The area of the whole island is 492,800 acres, or 779 sq. m., of which 368,000 acres belong to Lewis. In 1891 the population of Lewis was 27,045, of Harris 3681; in 1901 the population of Lewis was 28,537, of Harris 3803, or 32,160 for the island, of whom 17,175 were females, 11,209 spoke Gaelic only, and 17,685 both Gaelic and English. There is communication with certain ports of the Western Highlands by steamer via Stornoway every week—often during the tourist and special seasons—the steamers frequently calling at Loch Erisort, Loch Seilg, Ardtourlie, Tarbert, Ardve, Rodel and The Obe. The coast is indented to a remarkable degree, the principal sea-locks in Harris being East and West Loch Tarbert; and in Lewis, Loch Seilgforth, Loch Erisort, and Broad Bay. The extreme districts of Harris are on the east coast and Loch Roag and Loch Resort on the west. The mainland is dotted with innumerable fresh-water lakes. The island is composed of gneiss rocks, excepting a patch of granite near Carloway, small bands of intrusive basalt at Gress and in Eyre Peninsula and some Torridonian sandstone at Stornoway, Tong, Vatskirk and Carloway. Most of Harris is mountainous, there being more than thirty peaks exceeding 1000 ft. high. Lewis is comparatively flat, save in the south-east, where Ben More reaches 1784 ft., and in the south-west, where Meallabhal (1888) is the highest point; but in this division there are only eleven peaks exceeding 1000 ft. in height. The rivers are small and unimportant. The principal capes are the Butt of Lewis, in the extreme north, where the cliffs are nearly 150 ft. high and crowned with a lighthouse, the light of which is visible for 10 m.; Tolsta Head, Triumpan Head and Cabag Head, on the east; Renish Point, in the extreme south; and, on the west, Toe Head and Gallon Head. The following inhabited islands in the Inverness-shire division belong to the parish of Harris: off the S.W. coast, Bernera (pop. 524), Ensay, Kislay and Pabbay; off the W. coast, Scarp (160), Soay and Tallnessy (72); off the E. coast, Scalp (387) and Scottasa. Belonging to the county of Ross and Cromarty are Great Bernera (389) to the W. of Lewis, in the parish of Uig, and the Shiant Isles, about 21 m. S. of Stornoway, in the parish of Lochs, so named from the number of its sea lochs and fresh-water lakes. The south-easterly base of Broad Bay is furnished by the peninsula of Eye, attached to the main mass by so slender a neck as seemingly to be on the point of becoming itself an island. Much of the surface of both Lewis and Harris is composed of peat and swamp; there are scanty fragments of an ancient forest. The rainfall for the year averages 41.7 in., autumn and winter being very wet. Owing to the influence of the Gulf Stream, however, the temperature is fairly high, averaging for the year 46° F., for January 39° F. and for August 53° F.

The economic conditions of the island correspond with its physical conditions. The amount of cultivable land is small and poor. Sir James Matheson (1796–1878), who purchased the island in 1844, is said to have spent nearly £35,000 in reclamation and improvements. Barley and potatoes are the chief crops. A large number of black cattle are reared and some sheep-farming is carried on in Harris. Kelp-making, once important, has been extinct for many years. Harris has obtained great reputation for tweeds. The cloth has an aroma of heather and peat, and is made in the dwellings of the crofters, who use dyes of long-established excellence. The fisheries are the principal mainstay of the people. In spite of the very considerable reductions in rent effected by the Crofters’ Commission (appointed in 1886) and the sums expended by government, most of the crofters still live in poor huts amid dismal surroundings. The island affords good sporting facilities. Many of the streams abound with salmon and trout; otters and seals are plentiful, and deer and hares common; while bird life includes grous, ptarmigan, woodcock, snipe, heron, widgeon, teal, eider duck, swan and varieties of geese and gulls. There are many antiquarian remains, including duns, megaliths, ruined towers and chapels and the like. At Roatz, in the extreme north of Harris, is a church, all that is left of an Augustinian monastery. The foundation is Norman and the superstructure Early English. On the towers are curious carved figures and in the interior several tombs of the Macleods, the most remarkable being that of Alastair (Alexander), son of William Macleod of Dunvegan, dated 1528. The monument, a full-length recumbent effigy of a knight in armour, lies at the base of a tablet in the shape of an arch divided into compartments, in which are carved in bas-relief, besides the armorial bearings of the deceased and a rendering of Dunvegan castle, several symbolical scenes, one of which exhibits Satan weighing in the balance the good and evil deeds of Alastair Macleod, the good obviously preponderating. Stornoway, the chief town (pop. 3852) is treated under a separate heading. At Callernish, 23 m. due W. of Stornoway, are several stone circles, the one of which is probably the most perfect on the west coast and is known as the ‘‘Druidical’’ structures in the British Isles. In this specimen the stones are huge, moss-covered, undressed blocks of gneiss. Twelve of such monoliths constitute the circle, in the centre of which stands a pillar 17 ft. high. From the circle there runs northwards an avenue of stones, comprising on the right-hand side nine blocks and on the left-hand ten. There also branch off from the circle, on the east and west, a single line of four stones and, on the south, a single line of five stones. From the extreme point of the circle south to the farther
end of the avenue on the north is a distance of 127 yds. and the width from tip to tip of the east and west arms is 41 yds. Viewed from the north end of the avenue, the design is that of a cross. The most important fishery centre on the west coast is Carlaway, where there is the best example of a broch, or fort, in the Hebrides. Rory, the blind harper who translated the Psalms into Gaelic, was born in the village. Tarbert, at the head of East Loch Tarbert, is a neat, clean village, in communication by mail-car with Stornoway. At Coll, a few miles N. by E. of Stornoway, is a mussel cave; and at Gress, 2 m. or so beyond in the same direction, there is a famous seals' cave, adorned with fine stalactites. Port of Ness, where there is a harbour, is the headquarters of the fishing industry. Loch Seafarth gave the title of earl to a branch of the Mackenzies, but in 1716 the 5th earl was also created Lord Jacobitism and the title forfeited. In 1797 Francis Humberston Mackenzie (1754-1815), chief of the Clan Mackenzie, was created Lord Seaforth and Baron Mackenzie of Kintail, and made colonel of the 2nd battalion of the North British Militia, afterwards the 3rd battalion of the Seaforth Highlanders. The 2nd battalion of the Seaforth Highlanders was formerly the Ross-shire Buffs, which was raised in 1772.

LEXICON, a dictionary (q.v.). The word is the Latinized form of Gr. λεξικόν, sc. βιβλιαριον, a word-book (λέξις, word, λεξιον, to speak). Lexicon, rather than dictionary, is used of word-books of the Greek language, and sometimes of Arabic and Hebrew.

LEXINGTON, BARON, a title borne in the English family of Sutton from 1645 to 1723. Robert Sutton (1590-1668), son of Sir William Sutton of Averham, Nottinghamshire, was a member of parliament for his native county in 1625 and again in 1640. He served Charles I. during the Civil War, making great monetary sacrifices for the royal cause, and in 1645 the king created him Baron Lexington, this being a variant of the name of the Nottinghamshire village of Laxton. His estate suffered during the time of the Commonwealth, but some money was returned to him by Charles II. He died on 13th of October 1668. His only son, Robert, the 2nd baron (1661-1723), supported in the House of Lords the elevation of William of Orange to the throne, and was employed by that king at court and on diplomatic business. He also served as a soldier, but he is chiefly known as the British envoy at Vienna during the conclusion of the treaty of Ryswick, and at Madrid during the negotiations which led to the treaty of Utrecht. He died on the 10th of September 1723. His letters from Vienna, selected and edited by the Hon. H. M. Sutton, were published as the Lexinton Papers (1831). Lexington's barony became extinct on his death, but his estates descended to the younger sons of his daughter Bridget (d. 1734), the wife of John Manners, 3rd. Duke of Rutland. George Manners, who inherited these estates in 1762, is the ancestor of the family of Manners-Sutton. An earlier member of this family is Oliver Sutton, bishop of Lincoln from 1280 to 1290.

LEXINGTON, a city and the county-seat of Fayette county, Kentucky, U.S.A., about 75 m. S. of Cincinnati. Pop. (1900) 26,360, of whom 10,130 were negroes and 224 were foreign-born; (1910 census), 35,069. It is served by the Louisville & Nashville, the Southern, the Chesapeake & Ohio, the Cincinnati, New Orleans & Texas Pacific, the Lexington & Eastern, and electric railways. The city, which lies at an altitude of about 930 ft., is situated near the centre of the celebrated "blue grass" region, into which extend a number of turnpike roads. Its public buildings include the court house and the federal building, both built of Bowling Green oolitic limestone. Among the public institutions are two general hospitals—St Joseph's (Roman Catholic) and Good Samaritan (controlled by the Protestant churches of the city)—the Eastern Lunatic Asylum (1815, a state institution since 1824), with 250 acres of grounds; a state House of Reform for Girls and a state House of Reform for Boys (both at Greendale, a suburb); an orphan industrial school (for negroes); and two Widows' and Orphans' Homes, one established by the Odd Fellows of Kentucky and the other by the Knights of Pythias of the state. Lexington is the seat of Transylvania University (non-sectarian; coeducational), formerly Kentucky University (Disciples of Christ), which grew out of Bacon College (opened at Georgetown, Ky., in 1836), was chartered in 1858 as Kentucky University, and was opened at Harrodsburg, Ky., in 1859, whence after a fire in 1864 it removed to Lexington in 1865. At Lexington it was consolidated with the old Transylvania University, a well-known institution which had been chartered as Transylvania Seminary in 1785, was opened near Danville, Ky., in 1785, was removed to Lexington in 1789, was re-chartered as Transylvania University in 1798, and virtually ceased to exist in 1850. In 1907 Lexington University resumed the old name, Transylvania University. It has a college of Liberal Arts, a College of Law, a Preparatory School, a Junior College for Women, and Hamilton College for women (founded in 1869 as Hocker Female College), over which the university assumed control in 1903, and a College of the Bible, organized in 1865 as one of the colleges of the university, but now under independent control. In 1907-1908 Transylvania University, including the College of the Bible, had 1129 students. At Lexington are the State University, two colleges for girls—the Campbell-Hagerman College and Sayre College—and St Catherine's Academy (Roman Catholic). The city is the meeting-place of a Chatauqua Assembly, and has a library. The State University was founded (under the Federal Land Grant Act of 1862) in 1865 as the State Agricultural and Mechanical College, was opened in 1866, and was a college of Kentucky University until 1878. In 1890 the college received a second Federal appropriation, and it received various grants from the state legislature, which in 1880 imposed a state tax of one-half of 1% for its support. In connexion with it an Agricultural Experiment Station was established in 1885. In 1908 its title became, by act of Legislature, the State University. The university has a College of Agriculture, a College of Arts and Science, a College of Law, a School of Civil Engineering, a School of Mechanical and Electrical Engineering; and a School of mining and Metallurgical Engineering. The university campus is the former City Park, in the southern part of the city. In 1907-1908 the university had 1664 students. The city is the see of a Protestant Episcopal bishopric.

Lexington was the home of Henry Clay from 1797 until his death in 1852, and in his memory a monument has been erected, consisting of a magnesian-limestone column (about 120 ft.) in the Corinthian style and surmounted by a statue of Clay, the head of which was torn off in 1902 by a thunderbolt. Clay's estate, "Ashland," is now one of the best known of the stock-farms in the vicinity; the present house is a replica of Clay's home. The finest and most extensive of these stock-farms, and probably the finest in the world, is "Elmendorf," 6 m. from the city. On these farms many famous trotting and running horses have been raised. There are two race-tracks in Lexington, and annual running and trotting race meetings attract large crowds. The city's industries consist chiefly in a large trade in tobacco, hemp, grain and live stock—there are large semi-annual horse sales—and in the manufacture of "bourbon" whisky, tobacco, flour, dressed flax and hemp, carriages, harness and saddles. The total value of the city's factory products in 1905 was $7,77,439 (46-0% more than in 1900).

Lexington was named from Lexington, Massachusetts, in 1775 by a party of hunters who were encamped here when they received the news of the battle of Lexington; the permanent settlement dates from 1779. It was laid out in 1781, incorporated as a town in 1782, and chartered as a city in 1832. The first newspaper published west of the Allegheny Mountains, the Kentucky Gazette, was established here in 1787, to promote the separation of Kentucky from Virginia. The first state legislature met here in 1792, but later in the same year Frankfort became the state capital. Until 1907, when the city was enlarged by 50%, its limits remained as they were first laid out, a circle with a radius of 1 m., the court house being its centre.

C. W. Ranck, History of Lexington, Kentucky (Cincinnati, 1872).
LEXINGTON. a township of Middlesex county, Massachusetts, U.S.A., about 11 m. N.W. of Boston. Pop. (1900) 4190. (1910 U.S. census) 4018. It is traversed by the Boston & Maine railroad and by the Lowell & Boston electric railway. Its area is about 17 sq. m., and it contains three villages—Lexington, East Lexington and North Lexington. Agriculture is virtually the only industry. Owing to its historic interest the village of Lexington is visited by thousands of persons annually, for it was on or near this common of the village that the first armed conflict of the American War of Independence occurred. On the green a monument erected by the state in 1799 to the memory of the minute-men who fell in that engagement, a drinking fountain surmounted by a bronze statue (1900, by Henry Hudson Kitson) of Captain John Parker, who was in command of the minute-men, and a large boulder, which marks the position of the minute-men when they were fired upon by the British. Near the green, in the old burying-ground, are the graves of Captain Parker and other American patriots—the oldest gravestone is dated 1696. The Hancock-Clarke House (built in part in 1689) is now owned by the Lexington Historical Society and contains a museum of revolutionary and other relics, which were formerly exhibited in the Town Hall. The Buckman Tavern (built about 1690), the rendezvous of the minute-men, and the Munroe Tavern (1695), the headquarters of the British, are still standing, and two other houses, on the common, antedate the War of Independence. The Cary Library in this village, with 25,000 volumes (1908), was founded in 1868, and was housed in the Town Hall from 1871 until 1906, when it was removed to the Cary Memorial Library building. In the library are portraits of Paul Revere, William Dawes and Lord Percy. The Town Hall (1871) contains statues of John Hancock (by Thomas R. Gould) and Samuel Adams (by Martin Millmore), of the "Minute-Man of 1775" and the "Soldier of 1861," and a painting by Henry Sandham, "The Battle of Lexington."

Lexington was settled as a part of Cambridge as early as 1642.

It was organized as a parish in 1661 and was made a township (probably named in honour of Lord Lexington) in 1713. In the evening of the 18th of April 1775 a British force of about 800 men under Lieut.-Colonel Francis Smith and Major John Pitcairn was sent by General Thomas Gage from Boston to destroy military stores collected by the colonists at Concord, and to seize John Hancock and Samuel Adams, then at Parson Clarke's house (now known as the Hancock-Clarke House) in Lexington. Although the British had tried to keep this movement a secret, Dr Joseph Warren discovered their plans and sent out Paul Revere and William Dawes to give warning of their approach. The expedition had not proceeded far when Smith, discovering that the country was aroused, despatched an express to Boston for reinforcements and ordered Pitcairn to hasten forward with a detachment of light infantry. Early in the morning of the 19th Pitcairn arrived at the green in the village of Lexington, and there found between sixty and seventy minute-men under Captain John Parker drawn up in a brisk line of battle, while the order of march was in disorder on their refusal to do so his men fired a volley. Whether a stray shot preceded the first volley, and from which side it came, are questions which have never been determined. After a second volley the British, Parker ordered his men to withdraw. The engagement lasted only a few minutes, but eight Americans were killed and nine wounded; not more than two or three of the British were wounded. Hancock and Adams had escaped before the British troops reached Lexington. The British proceeded from Lexington to Concord (q.v.). On their return they were continually fired upon by Americans from behind trees, rocks, buildings and other defences, and were threatened with complete destruction until they were rescued at Lexington by a force of 1000 men under Lord Hugh Percy (later, 1786, duke of Northumberland). Percy received the fugitives within a hollow square, checked the onslaught for a time with two field-pieces, used the Munroe Tavern for a hospital, and later in the day carried his command with little further injury back to Boston. The British losses for the entire day were 73 killed, 174 wounded and 5 missing; the American losses were 49 killed, 39 wounded and 5 missing.

In 1839 a state normal school for women (the first in Massachusetts and the first public training school for teachers in the United States) was opened at Lexington; it was transferred to West Newton in 1844 and to Framingham in 1853.

See Charles Hudson, History of the Town of Lexington (Boston, 1868), and the publications of the Lexington Historical Society, (1890 seq.).

LEXINGTON, a city and the county-seat of Lafayette county, Missouri, U.S.A., situated on the S. bank of the Missouri river, about 40 m. E. of Kansas City. Pop. (1900) 4190, including 1170 negroes and 283 foreign-born; (1910) 5242. It is served by the Atchison, Topeka & Santa Fé, the Wabash (at Lexington Junction, 4 m. N.W.), and the Missouri Pacific railway systems. The city lies for the most part on high ground at the summit of the river bluffs, but in part upon their face. Lexington is the seat of the Lexington College for Young Women (Baptist, established 1855), the Central College for Women (Methodist Episcopal, South; opened 1860), and the Wentworth Military Academy (1886). There are steam flour mills, furniture factories and various other small manufactories; but the main economic interest of the city is in brickyards and coal-mines in its immediate vicinity. It is one of the principal coal centres of the state. Lexington was founded in 1819, was laid out in 1832, and, with various additions, was chartered as a city in 1845. A new charter was received in 1870. Lexington succeeded Sibley as the eastern terminus of the Santa Fé trade, and was in turn displaced by Independence; it long owed its prosperity to the freighting trade up the Missouri, and at the opening of the Civil War it was the most important river town between St Louis and St Joseph and commanded the approach by water to Fort Leavenworth.

After the Confederate success at Wilson's Creek (Aug. 10, 1861), General Price advanced northward, and with about 15,000 men arrived in the vicinity of Lexington on the 12th of September. Here he found a Federal force of about 3800 men under Colonel James A. Mulligan (1830-1864) throwing up intrenchments on Masonic College Hill, an eminence adjoining Lexington on the N.E. An attack was made on the same day and the Federals were driven within their defences, but at night General Price withdrew to the Fair-grounds not far away and remained there five days waiting for his wagon train and for reinforcements. On the 18th the assault was renewed, and on the 20th the Confederates, advancing behind movable breastworks of water-soaked bales of hemp, forced the besieged, now long without water, to surrender. The losses were: Confederate, 25 killed and 75 wounded; Federal, 39 killed and 120 wounded. At the end of September General Price withdrew, leaving a guard of only a few hundred in the town, and on the 16th of the next month a party of 220 Federal scouts under Major Frank J. White (1837-1875) surprised this guard, released about 13 prisoners, and captured 6 firearms and 6 more Confederates. Another Federal raid on the town was made in December of the same year by General John Pope's cavalry. Again, during General Price's Missouri expedition in 1864, a Federal force entered Lexington on the 16th of October, and three days later there was some fighting about 4 m. S. of the town.

LEXINGTON, a town and the county-seat of Rockbridge county, Virginia, U.S.A., on the North river (a branch of the James), about 30 m. N.N.W. of Lynchburg. Pop. (1900) 3203 (1257 negroes); (1910) 3293. It is served by the Chesapeake & Ohio and the Baltimore & Ohio railways. The famous Natural Bridge is about 16 m. S.W., and there are mineral springs in the vicinity—at Rockbridge Baths, 10 m. N., at Wilson's Springs, 13 m. N., and at Rockbridge Alum Springs, 17 m. N. Lexington is best known as the seat of Washington and Lee University, and of the Virginia Military Institute. The former grew out of Augusta Academy, which was established in 1740 in Augusta county, about 15 m. S.W. of what is now the city of Staunton, was renamed Liberty Hall and was established near
LEYDEN in 1780, and was chartered as Liberty Hall Academy in 1782. In 1785 its name was changed to Washington Academy, in recognition of a gift from George Washington of some shares of canal stock, which he refused to receive from the Virginia legislature. In 1802 the Virginia branch of the Society of the Cincinnati disbanded and turned over to the academy its funds, about $25,000; in 1813 the academy took the name Washington College; and in 1871 its corporate name was changed to Washington and Lee University, the addition to the name being made in honour of General Robert E. Lee, who was the president of the college from August 1865 until his death in 1870. He was succeeded by his son, General George Washington Custis Lee (b. 1820), president from 1871 to 1897, and Dr William Lyne Wilson (1843-1900), the eminent political leader and educator, was president from 1897 to 1900. In 1908-1909 the university comprised a college, a school of commerce, a school of engineering and a school of law, and had a library of 47,000 volumes, 23 instructors and 563 students. In the Lee Memorial chapel, on the campus, General Robert E. Lee is buried, and over his grave is a notable recumbent statue of him by Edward Virgil Anderson (1858-1911). The Virginia Military Institute was established in March 1929, when its cadet corps supplanted the company of soldiers maintained by the state to garrison the Western Arsenal at Lexington. The first superintendent (1810-1810) was General Francis Henney Smith (1812-1890), a graduate (1835) of the United States Military Academy; and from 1831 until the outbreak of the Civil War "Stonewall" Jackson was a professor in the Institute—he is buried in the Lexington cemetery and his grave is marked by a monument. On the campus of the institute is a fine statue, "Virginia Mourning Her Dead," by Moses Ezekiel (b. 1824), which commemorates the gallantry of a battalion of 250 cadets from the institute, more than 50 of whom were killed or wounded during the engagement at New Market on the 15th of May 1864. In 1908-1909 the institute had 27 instructors and 330 cadets. Flour is manufactured in Lexington and lime in the vicinity. The town owns and operates its water-works. The first settlers of Rockbridge County established themselves in 1737 near the North river, a short distance below Lexington. The first permanent settlement on the present site was made about 1778. On the 11th of June 1864, during the occupation of the town by Federal troops under General David Hunter, most of the buildings in the town and those of the university were damaged and all those of the institute, except the superintendent’s headquarters, were burned.

LEYDEN, JOHN (1775-1811), British orientalist and man of letters, was born on the 8th of September 1775 at Denholm on the Teviot, not far from Hawick. Leyden's father was a shepherd, but contrived to send his son to Edinburgh University to study for the ministry. Leyden was a diligent but somewhat miscellaneous student, reading everything apparently, except theology, for which he seems to have had no taste. Though he completed his divinity course, and in 1798 received licence to preach from the presbytery of St Andrews, it soon became clear that the pupil was not his vocation. In 1794 Leyden had formed the acquaintance of Dr Robert Anderson, editor of The British Poets, and of The Literary Magazine. It was Anderson who introduced him to Dr Alexander Murray, and Murray probably who led him to the study of Eastern languages. They became warm friends and generous rivals, though Leyden excelled, perhaps, in the rapid acquisition of new tongues and acquaintance with their literature, while Murray was the more scientific philologist. Through Anderson also he came to know Richard Heber, by whom he was brought under the notice of Sir Walter Scott, who was then collecting materials for his Minstries of the Scottish Border. Leyden was admirably fitted for helping in this kind of work, for he was a borderer himself, and an enthusiastic lover of old ballads and folk-lore. Scott tells how, on one occasion, Leyden walked 40 m. to get the last two verses of a ballad, and returned at midnight, singing it all the way with his loud, harsh voice, to the wonder and consternation of the poet and his household.

Leyden meanwhile compiled a work on the Discoveries and Settlements of Europeans in Northern and Western Africa, suggested by Mungo Park’s travels, edited The Complaint of Scotland, printed a volume of Scottish descriptive poems, and nearly finished his Scenes of Infancy, a diffuse poem based on border scenes and traditions. He also made some translations from Eastern poetry, Persian and Arabic. At last his friends got him an appointment in India on the medical staff, for which he qualified by a year’s hard work. In 1803 he sailed for Madras, and took his place in the general hospital there. He was promoted to be naturalist to the commissioners going to survey Mysore, and in 1807 his knowledge of the languages of India procured him an appointment as professor of Hindustani at Calcutta; this he soon after resigned for a judgeship, and that again to be a commissioner in the court of requests in 1809, a post which required a familiarity with several Eastern tongues. In 1811 he joined Lord Minto in the expedition to Java. Having entered a library which was said to contain many Eastern MSS, without having the place aired, he was seized with Batavian fever, and died, after three days’ illness, on the 28th of August 1811.

LEYDEN JAR, or CONDENSER, an electrical appliance consisting in one form of a thin glass jar partly coated inside and outside with tin foil, or in another of a number of glass plates similarly coated. When the two metal surfaces are connected for a short time with the terminals of some source of electro motive force, such as an electric machine, an induction coil or a voltaic battery, electric energy is stored up in the condenser in the form of electric strain in the glass, and can be recovered again in the form of an electric discharge.

The earliest form of Leyden jar consisted of a glass vial or thin Florence flask, partly full of water, having a metallic nail inserted through the cork which touched the water. The bottle was held in the hand, and the nail presented to the prime conductor of an electrical machine. If the person holding the bottle subsequently touched the nail, he experienced an electric shock. This experiment was first made by E. G. von Kleist of Kamnin in Pomerania in 1745, and it was described in another form in 1746 by Cunaeus and P. van Mussenbroek, of the university of Leyden (Leiden), whence the term Leyden jar. 1 J. H. Winkler discovered that an iron chain wound round the bottle could be substituted for the hand, and Sir William Watson in England shortly afterward showed that iron filings or mercury could replace the water within the jar. Dr John Bevis of London suggested, in 1746, the use of sheet lead coatings within and without the jar, and subsequently the use of tin foil or silver leaf made closely adherent to the glass. Benjamin Franklin and Bevis devised independently the form of condenser known as a Franklin or Leyden pane, which consists of a sheet of glass, partly coated on both sides with tin foil or silver leaf, a margin of glass all round being left to insulate the two tin foils from each other. Franklin in 1747 and 1748 made numerous investigations on the Leyden jar, and devised a method of charging jars in series as well as in parallel. In the former method, now commonly known as charging in cascade, the jars are insulated and the outside coating of one jar is connected to the inside coating of the next and so on for a whole series, the inside coating of the first jar and the outside coating of the last jar being the terminals of the condenser. For charging in parallel a number of jars are collected in a box, and all the outside coatings are connected together metallically and all the inside coatings brought to one common terminal. This arrangement is commonly called a battery of Leyden jars. To Franklin also we owe the important knowledge that the electric charge resides really in the glass and not in the metal coatings, and that when a condenser has been charged the metallic coatings can be exchanged for fresh ones and yet the electric charge of the condenser remains.

In its modern form the Leyden jar consists of a wide mouthed bottle of thin English flint glass of uniform thickness, 1 Park Benjamin. The Intellectual Rise in Electricity. p. 512. 2 Ibid. p. 519.
free from flaws. About half the outside and half the inside surface is coated smoothly with tin foil, and the remainder of the glazed surface is painted with shellac varnish. A wooden stopper closes the mouth of the jar, and through it a brass rod passes which terminates in a chain, or better still, three elastic brass springs, which make good contact with the inner coating. The rod terminates externally in a knob or screw terminal. The jar has a certain capacity C which is best expressed in microfarads or electrostatic units (see ELECTROSTATICS), and is determined by the surface of the tin foil and thickness and quality of the glass. The jar can be charged so that a certain potential difference V, reckoned in volts, exists between the two coatings. If a certain critical potential is exceeded, the glass gives way under the electric strain and is pierced. The safe voltage for most glass jars is about 20,000 volts for glass $\frac{2}{3}$ths in. in thickness; this corresponds with an electric spark of about 7 millimetres in length.

When the jar is charged, it is usually discharged through a metallic arc called the discharging tongs, and this discharge is in the form of an oscillatory current (see ELECTROKINETICS). The energy stored up in the jar in joules is expressed by the value of $\frac{1}{2} CV^2$, where C is the capacity measured in farads and V the potential difference of the coatings in volts. If the capacity C is reckoned in microfarads then the energy storage is equal to $\frac{1}{2} CV^2 \times 10^{-9}$ joules or $\frac{1}{2} CV^2 \times 10^{-6}$ foot-pounds. The size of jar commonly known as a quart size may have a capacity from $\frac{1}{2}$ to $\frac{1}{4}$ of a microfarad, and if charged to 20,000 volts stores up energy from a quarter to half a joule or from $\frac{1}{6}$ to $\frac{1}{4}$ of a foot-pound.

Leyden jars are now much employed for the production of the high frequency electric currents used in wireless telegraphy (see TELEGRAPHY, WIRELESS). For this purpose they are made by Moserick in the form of glass tubes partly coated by silver chemically deposited on the glass on the inner and outer surfaces. The tubes have walls thicker at the ends than in the middle, as the tendency to puncture the glass is greatest at the edges of the coatings. In other cases, Leyden jars or condensers take the form of sheets of mica or micalet or ebonite partly coated with tin foil or silver leaf on both sides; or a pile of sheets of alternate tin foil and mica may be built up, the tin foil sheets having lugs projecting out first on one side and then on the other. All the lugs on one side are connected together, and so also are all the lugs on the other side, and the two sets of tin foil separated by sheets of mica constitute the two metallic surfaces of the Leyden jar condenser. For the purposes of wireless telegraphy, when large condensers are required, the ordinary Leyden jar occupies too much space in comparison with its electrical capacity, and hence the best form of condenser consists of a number of sheets of crown glass, each partly coated on both sides with tin foil. The tin foil sheets have lugs attached which project beyond the glass. The plates are placed in a vessel full of insulating oil which prevents the glow or brush discharge taking place over their edges. All the tin foils on one side of the glass plates are connected together and all the tin foils on the opposite sides, so as to construct a condenser of any required capacity. The box should be of glass or stoneware or other non-conducting material. When glass tubes are used it is better to employ tubes thicker at the ends than in the middle, as it has been found that when the safe voltage is exceeded and the glass gives way under electric strain, the piercing of the glass nearly always takes place at the edges of the tin foil.

Glass is still commonly used as a dielectric because of its cheapness, high dielectric strength or resistance to electric puncture, and its high dielectric constant (see ELECTROSTATICS). It has been found, however, that very efficient condensers can be made with compressed air as dielectric. If a number of metal plates separated by small distance pieces are enclosed in an iron box which is pumped full of air to a pressure, say, of 100 lb. to 1 sq. in., the dielectric strength of the air is greatly increased, and the plates may therefore be brought very near to one another without causing a spark to pass under such voltage as would cause discharge in air at normal pressures. Condensers of this kind have been employed by R. A. Fessenden in wireless telegraphy, and they form a very excellent arrangement for standard condensers with which to compare the capacity of other Leyden jars. Owing to the variation in the value of the dielectric constant of glass with the temperature and with the frequency of the applied electromotive force, and also owing to electric glow discharge from the edges of the tin foil coatings, the capacity of an ordinary Leyden jar is not an absolutely fixed quantity, but its numerical value varies somewhat with the method by which it is measured, and with the other circumstances above mentioned. For the purpose of a standard condenser a number of concentric metal tubes may be arranged on an insulating stand, alternate tubes being connected together. One coating of the condenser is formed by one set of tubes and the other by the other set, the air between being the dielectric. Paraffin oil or any liquid dielectric of constant inductivity may replace the air.

LEYS, HENDRIK, BARON (1815-1866), Belgian painter, was born at Antwerp on the 18th of February 1815. He studied under Wappers at the Antwerp Academy. In 1833 he painted "Combat d'un grenadier et d'un cosaque," and in the following year "Combat de Bourguignons et Flamands." In 1835 he went to Paris where he was influenced by the Romantic movement. Examples of this period of his painting are "Massacre des échevins de Louvain," "Mariage flamand," "Le Roi des arbalétriers" and other works. Leys was an imitative painter in whose works may rapidly be detected the schools which he had been studying before he painted them. Thus after his visit to Holland in 1839 he reproduced many of the characteristics of the Dutch genre painters in such works as "Franz Floris se rendant à une fête" (1843) and "Service divin en Hollande" (1850). So too the methods of Quentin Matsys impressed themselves upon him after he had travelled in Germany in 1852. In 1862 Leys was created a baron. At the time of his death, which occurred in August 1860, he was engaged in decorating with fresco the large hall of the Antwerp Hôtel de Ville.

LEYTON, an urban district forming one of the north-eastern suburbs of London, England, in the Walthamstow (S.W.) parliamentary division of Essex. Pop. (1891) 63,166; (1901) 98,912. It lies on the east (left) bank of the Lea, along the flat open valley of which runs the boundary between Essex and the county of London. The church of St Mary, a brick reconstruction, contains several interesting memorials, including one to William Bowyer the printer (d. 1737), erected by his son and namesake, more famous in the same trade. Here is also buried John Strype the historian and biographer (d. 1737), who held the position of curate and lecturer at this church. Leyton is in the main a residential district as distinct from a manufacturing locality. Its name is properly Low Leyton, and the parish included the district of Leytonstone to the east. Roman remains have been discovered here, but no identification with a Roman station by name has been made with certainty. The ground of the Essex County Cricket Club is at Leyton.

LHASA (Lhasa, Lassa, "God's ground"), the capital of Tibet. It lies in 29° 39' N., 91° 5' E., 11,830 ft. above sea-level. Owing to the inaccessibility of Tibet and the political and religious exclusiveness of the lamas, Lhasa was long closed to European travellers, all of whom during the latter half of the 19th century were stopped in their attempts to reach it. It was popularly known as the "Forbidden City." But its chief features were known by the accounts of the earlier Romish missionaries who visited it and by the investigations, in modern times, of native Indian secret explorers, and others, and the British armed mission of 1904 (see Tibet).

Site and General Aspect.—The city stands in a tolerably level plain, which is surrounded on all sides by hills. Along its
southern side, about ¾ m. south of Lhasa, runs a considerable river called the Kyichu (Ki-chu) or Kyi, flowing here from E.N.E., and joining the great Tsangpo (or upper course of the Brahmaputra) some 35 m. to the south-west. The hills round the city are barren. The plain, however, is fertile, though in parts marshy. There are gardens scattered over it round the city, and these are planted with fine trees. The city is screened from view from the west by a rocky ridge, lofty and narrow, with summits at the north and south, the one flanked and crowned by the majestic buildings of Potala, the chief residence of the Dalai Lama, the other by the temple of medicine. Groves, gardens and open ground intervene between this ridge and the city itself for a distance of about 1 m. A gate through the centre of the ridge gives access from the west; the road thence to the north part of the city throws off a branch to the Yutok sampa or turquoise-tiled covered bridge, one of the noted features of Lhasa, which crosses a former channel of the Kyi, and carries the road to the centre of the town.

The city is nearly circular in form, and less than 1 m. in diameter. It was walled in the latter part of the 17th century, but the walls were destroyed during the Chinese occupation in 1722. The chief streets are fairly straight, but generally of no great width. There is no paving or metal, nor any drainage system, so that the streets are dirty and in parts often flooded. The inferior quarters are unspeakably filthy, and are rife with evil smells and large mangy dogs and pigs. Many of the houses are of clay and sun-dried brick, but those of the richer people are of stone and brick. All are frequently white-washed, the doors and windows being framed in bands of red and yellow. In the suburbs there are houses entirely built of the horns of sheep and oxen set in clay mortar. This construction is in some cases very roughly carried out, but in others it is solid and highly picturesque. Some of the inferior huts of this type are inhabited by the Bagyaba or scavengers, whose chief occupation is that of disposing of corpses according to the practice of cutting and exposing them to the dogs and birds of prey. The houses generally are of two or three storeys. Externally the lower part generally presents dead walls (the ground floor being occupied by small shops or apartments); above these rise tiers of large windows with or without projecting balconies, and over all flat broad-eaved roofs at varying levels. In the better houses there are often spacious and well-finished apartments, and the principal halls, the verandahs and terraces are often highly ornamented in brilliant colours. In every house there is a kind of chapel or shrine, carved and gilt, on which are set images and sacred books.

Temples and Monasteries.—In the centre of the city is an open square which forms the chief market-place. Here is the great temple of the chief Lama of Lhasa. It is believed to have been founded by the Tibetan Constantine, Srong-tsan-gampo, in 625, as the shrine of one of those two very sacred Buddhist images which were associated with his conversion and with the foundation of the civilized monarchy in Tibet. The temple is not so great in size as that at Samtse, but it is little above the level of other buildings which closely surround it, and the effect of its characteristic gilt roof, though conspicuous and striking from afar, is lost close at hand.

The temple is three storeys high. The entrance consists of a portico supported on timber columns, carved and gilt, while the walls are enwrought with Chinese, Mongolian and Tibetan characters, and a great prayer-wheel stands on one side. Mangy dogs and small monkeys often crowd near the altar for an annah, and from this second gate opens into a courtyard surrounded by a verandah with many pillars and chapels, and frescoes on its walls. On the left is the throne of the great lama, laid with cushions, together with the seats of other ecclesiastics variously elevated according to the rank of their occupants. An inner door with enclosed vestibule gives access to the quadrangular choir or chancel, as it may be called, though its centre is open to the sky. On either side of it are three chapels, and at the extremity is the peculiar "holy of holies," flanked by two gilt images of the coming Buddha, and screened by lattice-work. In it is the shrine on which sits the great image of Sakyamuni, set about with small figures, lamps and a variety of offerings, and richly jewelled, though the workmanship of the whole is crude. In the second and third storeys of the temple are shrines and representations of a number of gods and goddesses. The temple contains a vast accumulation of sacred relics, women and children, and horses and camels. The temple is surrounded by a strangelike brick wall, and adorned with a magnificent arch of nearly 40 m. long. The entrance was found by the members of the British mission who visited it to be exceedingly dirty, and the atmosphere was foul with the fumes of butter-lamps.

In the convent-cells, halls of study and magazines of precious lumber, buildings grouped about the Jokhang are occupied by the civil administration, e.g. as treasuries, customs office, courts of justice, &c., and there are also private apartments for the grand lama and other high functionaries. No woman is permitted to pass close to the temple within the precinct.

In front of the main entrance to the Jokhang, in the shadow of a sacred willow tree, stands a famous monument, the During monolith, which bears the inscribed record of a treaty of peace concluded in 807 B.C. between the king of Tibet and the emperor of China. Before this monument the apodase from Lamaisim, Langtha, brother and successor of the last-named king, is said to have been standing when a fanatic recluse, who had seen visions, was avenged by a vision to his persecuted faith, assassination him.

The famous Potala hill, covered by the palace of the Dalai lama, forms a majestic mountain of buildings; with its vast inward-sloping sides and its varied features, it is well known only in China.

The Jokhang, the temple of the great ceremonial of the Lamas, houses the sacred likeness of Buddha, which has been the object of veneration from ages. This central member of Potala is called the red palace from its crimson colour, which distinguishes it from the rest. It contains the principal halls and chapels and shrines of past Dalai lamas. The temple must also be noted for the work of sculpture, carving and other ornament, but the interior of Potala as a whole cannot compare in magnificence with the exterior. Among the numerous other buildings of note or near Potala hill, one is distinguished by the Chinese as one of the principal beauties of Lhasa. This is a temple not far from the base of the hill, in the middle of a lake which is surrounded by trees and shrubberies. This temple, called Lu-kang, is circular in form, with a loggia or porch round it, and is called the "serpent house," comes from the tradition of a serpent or dragon, which dwelt here and must be propitiated lest it should cause the waters to rise and flood Lhasa.

Another great and ancient temple called Ramo-che, at the north side of the city. This is also regarded as a foundation of Srong-tsan-gampo, and is said to contain the body of his Chinese wife and the second of the primeval pallada, the image that she brought with her to the Snow-lan mountain whence it is known as the small Jokhang. This temple is noted for the practice of magical arts. Its buildings are in a neglected condition.

Another monastery within the city is that of Moru, also on the north side, remarkable for its external order and cleanliness. Though facing the school of the lamas, it has but a plain but printing house in the convent garden. This convent was the temporary residence of the regent during the visit of the British mission in 1904. Other monasteries in or near the city are the Tsamling Ling or Gom-pa, the first having two large smoke chimneys, with the second at the west of the city; the Kundli Ling or Kundeling about 1 m. west of the city, at the foot of a low isolated hill called Chapo-chi. Three miles south, beyond the river, is the Tsemchog Ling or Tseochen Ling, and another great convent called Trilok. From these, as well as the lamas of the capital possess the sacred images of Buddha. Among the great lamas of the city, Jackom’s lama, is said to be above the rest. He is associated with the Dalai Lama’s regent, during his minority, was formerly chosen. The temple of medicine, as already stated, crowns the summit (Chagpa) at the end of the ridge west of the city, opposite to the headquarters of the convent associated with Losang. From this, as well as the lamas of the country possessing a religious system like that of Tibet the medical profession should form a branch of the priesthood. The treatment of disease, though based in some measure upon a judicious use of the common herbage and such like medicines, is not as well understood as superstition in a people, saturated with absurdity " (Waddell, Lhasa and Its Mysteries).

The three great monasteries in the vicinity of Lhasa, all claiming to be foundations of Tsongkhapa (1356-1418), the medieval reformer and organizer of the modern orthodox Lama Church, "the yellow caps," are the following:

1. Debng (written Brae spungs) is 6 m. west of Lhasa at the foot
of the hills which flank the plain on the north. It is one of the largest monasteries in the world, having some 8000 monks. In the middle of the convent buildings rises a kind of pavilion, brilliant with colours and gilding, which is occupied by the Dalai Lama when he visits Dalai on his summer and winter residence. The palace is the residence of the Mongol students who come to Lhasa to graduate, and is known in the country as the Mongol convent; it has also become the seat of political intrigue. Near it is the seat of the chief magician of Tibet, the Naching Cho-k'yon, a building picturesque in itself and in situation.

2. Sera is 3 m. north of the city on the activity of the hills and cliff. Below the pilgrimage to the monastery, the Nalchungu Monastery, the distance the crowd of buildings and temples, rising in amphitheatre against a background of rocky mountains, forms a pleasing picture. In the recesses of the hill, high above the convent, are scattered cells or private earthen tombs, each containing a relic or image, and celebrated as the resting-place of a famous Dorje, i.e. the Vajra or Thunderbolt of Jupiter, the symbol of the strong and indestructible, which the priest grasps and waves in various ways during prayer. The emblem is a bronze instrument, shaped much like a dumbbell with pointed ends, and it is carried solemnly in procession to the Jokhang during the New Year’s festival.

The hill adjoining Sera is believed to be rich in silver ore, but it is not allowed to be worked. On the summit is a spring and a holy place of the Lhasa Mahommedans, who resort thither. Near the monastery there is said to be gold, which is worked by the monks.

Saway is another famous convent intimately connected with Lhasa, being said to be used as a treasury by the government, but it lies some 36 m.-south-east on the left bank of the great Tsangpo. It was founded in 770, and is the oldest extant monastery in Tibet. It consists of a very high circular stone wall, 12 m. in circumference, with gates at the four points of the compass. On the north wall Nain Singh, who was here on his journey in 1874, counted 1030 votive piles of brick. One very large temple occupies the centre, and round it are four smaller but still large temples. Many of the idols are said to be of pure gold, and the wealth is very great. The interiors of the temples are covered with beautiful writing in enormous characters, which the vulgar believe to be the writing of Sakya himself.

Population and Trade.—The total population of Lhasa, including the lamas in the city and vicinity, is probably about 30,000; a census in 1854 made the figure 42,000, but it is known to have greatly decreased since. There are only some 1500 resident Tibetan laymen and about 5500 Tibetan women. The permanent population embraces, besides Tibetans, settled families of Chinese (about 2000 persons), as well as people from Nepal, from Ladak, and a few from Bhotan and Mongolia. The Ladakis and some of the other foreigners are Mahommedans, and much of the trade is in their hands. Desideri (1716) speaks also of Armenians and even "Muscovites." The Chinese have a crowded burial-ground at Lhasa, tended carefully after their manner. The Nepalese (about 800) supply the mechanics and menial labor. There are among them excellent gold- and silversmiths; and they make the huge gilded canopies crowning the temples. The chief industries are the weaving of a great variety of stuffs from the fine Tibetan wool; the making of earthenware and of the wooden porringers (varying immensely in elaboration and price) of which every Tibetan carries one about with him; also the making of certain fragrant sticks of incense much valued in China and elsewhere.

As Lhasa is not only the nucleus of a cluster of vast monastic establishments, which attract students and aspirants to the religious life from all parts of Tibet and Mongolia, but is also a great place of pilgrimage, the streets and public places swarm with visitors from every part of the Himalayan plateau, and from all the steppes of Asia between Manchuria and the Balkhash Lake. Naturally a great traffic arises quite apart from the

1 Among articles sold in the Lhasa bazaars are fossil bones, called by the people "lightning bones," and believed to have healing virtues.

LHASA 531

pilgrimage. The city thus swarms with crowds attracted by devotion and the love of gain, and presents a great diversity of language, costume and physiognomy; though, in regard to the last point, varieties of the broad face and narrow eye greatly predominate. Much of the retail trade of the place is in the hands of the women. The curious practice of the women in plastering their faces with a dark-coloured pigment is less common in Lhasa than in the provinces.

During December especially traders arrive from western China by way of Tachienlu bringing every variety of silk-stuffs, carpets, china-ware and tea; from Siningfu come silk, gold lace, Russian goods, carpets of a superior kind, semi-precious stones, horse furniture, horses. and a very large breed of fat-tailed sheep; also from Mongolia. Tibet finds its way to Europe through Nepal; from Bhotan and Sikkim, rice; from Sikkim also tobacco; besides a variety of Indian and European goods from Nepal and Darjeeling, and choras (resinous exudation of hemp) and saffron from Ladak and Kashmir. The merchants leave Lhasa in March, before the setting in of the rains renders the rivers impassable.

The tea importation from China is considerable, for tea is an absolute necessary to the Tibetan. The tea is of various qualities, from the coarsest, used only for "buttered" tea (a sort of broth), to the fine quality drunk by the wealthy. This is pressed into bricks or cakes weighing about 35 lb., and often passes as currency.

The quantity that pays duty at Tachienlu is about 10,000,000 lb., besides some amount smuggled. No doubt a large part of this comes to Lhasa.

Lhasa Festivities.—The greatest of these is at the new year. This lasts from three to five days, and is characterized by great displays of fireworks, and more or less by feasting, feasting, feasting, and every kind of display. There are plenty of shows and jugglers' performances. On one day a great pilgrimage to the Jokhang takes place. A long cable, twisted of leather thongs, is stretched from a high point in the battlements of Potula slanting down to the plain, where it is strongly moored. Two men slide from top to bottom of this huge unquestionable, sometimes lying on the chest (which is protected by a breast-plate of strong leather), spreading their arms as if to swim, and descending with the rapidity of an arrow-flight. Occasionally they are lashed with oxen, and sometimes they are shot with the arrows of the gods; but the survivors are rewarded by the court, and the Grand Lama himself is always a witness of it. This practice occurs more or less over the Himalayan plateau, and is known in the neighbouring countries of the Great Mogul, as well as in others of the world, and is a general custom on occasions of greatest reverence in cases of pestilence and the like. Exactly the same performance is described as having been exhibited in St Paul's Churchyard before King Edward VI., and again before Philip of Spain, as well as, about 1750, at Hertford and other places in England (see Strutt's 'Sports, &c.,' 2nd ed., p. 198).

The most remarkable celebration of the new year's festivities is the great jubilee of the Monlam (Mon-lam, "prayer"), instituted by Mongolpasa himself in 1408. Lamas from all parts of the country, chiefly from the great monasteries in the neighbourhood, flock to Lhasa, and every road leading thither is thronged with troops of monks on their way to the festival. In the convents near Lhasa, and in the country, the Tibetans exchange early visits, with their breviaries and their cooking-pots. Those who cannot find lodging bivouac in the streets and squares, or pitch their little black tents in the plain. The festival lasts six days, during which there reigns a great merriment. The first day is set apart to the Sublime Buddha, while gangs of lamas parade the streets, shouting, singing and coming to blows. The object of this gathering is, however, supposed to be devotional. Vast processions take place, with mystic offerings and large music, to the Jokhang and Maru convents; the Grand Lama himself assists at the festival, and from an elevated throne beside the Jokhang receives the offerings of the multitude and bestows his benediction.

On the 15th of the month multitudes of torches are kept ablaze, which light up the city to a great distance, whilst the interior of the Jokhang is illuminated throughout the night by innumerable lanterns shedding light on coloured figures in bas-relief, the worship of which takes place throughout the month. The growth of the history of Buddha and other subjects, all modelled in butter. The figures are executed on a large scale, and, as described by Huc, who witnessed the festival at Kunhum on the frontier of China, with extraordinary truth and skill. These singular works of art occupy some months in preparation, and on the morrow are shown
The holy Drepung is carried in solemn procession from Sera to the Jokhang, and to the presence of the lama at Potala.

Of other great annual feasts, one, in the fourth month, is assigned to the monastery of Sera, which is on the 18th of the month. The Omen is conducted by the king, and appears to connect itself with the old nature-feast of the entering of spring, and to be more or less identical with the Habb of India. A second, the consecration of the waters, in September–October, appears, on the confines of India, to be the same as the Dascha.

On the 30th day of the second month there takes place a strange ceremony, akin to that of the scapegoat, (which is not known in India). It is called the driving out of the demon. A man is hired to perform the part of a demon, (or victim rather), a part which sometimes ends fatally. He is fantastically dressed, his face mottled with white and black, and is then brought forth from the Jokhang to engage in quasi-religious controversy with one who represents the Grand Lama. It is a custom of this kind to connect with a certain curiosity by the name of Lord Miracle, who exercises arbitrary authority during that time for his own benefit, levying taxes and capricious fines upon the citizens.

History.—The seat of the princes whose family raised Tibet to a position among the powers of Asia was originally on the Ya-lung river, in the extreme east of the region now occupied by Tibetan tribes. It was transplanted to Lhasa in the 7th or 8th century by the king Srong-tsan-gampo, conqueror, civilization and proselytizer, the founder of Buddhism in Tibet, the introducer of the Indian alphabet. On the three-peaked crag now the ancient foundation of home, and King is said to have established his fortress, while he founded in the plain below temples to receive the sacred images, brought respectively from Nepal and from China by the princes to whom his own conversion is attributed.

Tibet endured as a conquering power some two centuries, and the more famous among the descendants of the founder added to the city. This Iong-de-tsang (who reigned 740–758) is said to have erected a great temple-palace of which the ancient followed the Tibetan style, the middle storey the Chinese, and the upper storey the Indian—a combination which would aptly symbolize the elements that have moulded the culture of Lhasa. His son, the last of the great orthodox kings, in the next century, is said to have summoned artists from Nepal and India, and among many splendid foundations that have erected a sanctuary (at Samyé) of vast height, which had nine storeys, the three lower of stone, the three middle of brick, the three uppermost of timber. With this king the glory of Tibet and of ancient Lhasa reached its zenith, and in 822, a monument recording his treaty on equal terms with the Great T'ang emperor of China was erected in the city. There followed dark days for Lhasa and the Buddhist church in the accession of this king's brother Lang-dharma, who has been called the Julian of the lamassus. This king rejected the doctrine, persecuted, and scattered its ministers, and threw down its temples, convents and images. It was more than a century before Buddhism recovered its hold and its convents were rehabilitated over Tibet. The country was then split into an infinity of petty states, many of them ruled from the convents by warlike ecclesiastics; but, though the old monarchy never recovered, Lhasa still retained something of its importance, and probably never lost its claim to be the chief city of that congeries of principalities, with a common faith and a common language, which was called Tibet.

The Arab geographers of the 10th century speak of Tibet, but without real knowledge, and none speaks of any city that we can identify with Lhasa. The first passage in any Western author in which such identification can be probably traced occurs in the narrative of Friar Odoric of Pordenone (c. 1320).

This remarkable traveller's route from Europe to India, and thence by sea to China, can be traced satisfactorily, but of his journey homeward through Asia the indications are very fragmentary. He speaks, however, on this return journey of the realm of Tibet, which lay on the confines of India proper:

"The king of that country dwells in tents made of black felt. But the chief and royal city is all built with walls of blue and white, and all its streets are very well paved. In this city no one shall dare to shed the blood of any, whether man or beast, for the reverence they bear a certain idol that is there worshipped. In that city dwelteth the Abassi, i.e. in their tongue the pole, who is the head of all the idolaters, and has the disposal of all their benefices such as they are after their manner."

We know that Kublai Khan had constituted a young prince of the Lama Church, Mati Dhawaja, as head of that body, and tributary ruler of Tibet, but besides this all is obscure for a century. This passage of Odoric shows that such authority continued under Kublai's descendants, and that some foreshadow of the position since occupied by the Dalai Lama already existed. But it was not till a century after Odoric that the strange heredity of the dynasty of the Dalai Lamas of Lhasa actually began. In the first two centuries of its existence the residence of these pontiffs was rather at Debung or Sera than at Lhasa itself, though the latter was the centre of devout resort. A great event for Lhasa was the conversion, or reconversion, of the Mongols to Lamaism (c. 1257), which made the city the focus of sanctity and pilgrimage to so vast a tract of Asia. It was in the middle of the 17th century that Lhasa became the residence of the Dalai Lama. A native prince, known as the Tsangpo, with his seat at Shigatse, had made himself master of southern Tibet, and threatened to absorb the whole. The fifth Dalai Lama, Nagwang Lobzang, called in the aid of a kalmuck prince, Gushi Khan, from the neighbour of the Koko-nor, who defeated and slew the Tsangpo and made over full dominion in Tibet to the lama (1641). The latter now established his court and built his palace on the rock-site of the fortress of the ancient monachy, which apparently had fallen into ruin, and to this he gave the name of Potala.

The founder of Potala died in 1681. He had appointed as a "regent" or civil administrator (Deisri, or Deba) one supposed to be his own natural son. This remarkable personage, Sangye Gyanmotso, of great ambition and accomplishment, still renowned in Tibet as the author of some of the most valued works of the native literature, concealed the death of his master, asserting that the latter had retired, in mystic meditation or trance, to the upper chambers of the palace. The government continued to be carried on in the lama's name by the regent, who engaged with Galdan Khan of Manzur against the Chinese (Manchu) power. It was not till the great emperor Kang-hi was marching on Tibet that the death of the lama, sixteen years before, was admitted. A solemn funeral was then performed, at which 108,000 lamas assisted, and a new incarnation was set up in the person of a youth of fifteen, Tsangs-yang Gyanmotso. This young man was the scandal of the Lamaiist Church in every kind of evil living and debauchery, so that he was deposed and assassinated in 1701. But it was under him and the regent Sangye Gyanmotso that the Potala palace attained its present scale of grandeur, and that most of the other great buildings of Lhasa were extended and embellished.

For further history and bibliography, see TIBET. Consult also LAMAISM.

L'HÔPITAL (or L'HOSPI). MICHEL DE (c. 1595–1733), French statesman, was born near Aigueperse in Auvergne (now near-le-Dôme). His father, who was physician to the constable Charles de Bourbon, sent him to study at Toulouse, where, at the age of eighteen he was driven, a consequence of the evil fortunes of the family patron, to Padua, where he studied law and letters for about six years. On the completion of his studies he joined his father at Bologna, and afterwards, the constable having died, went to Rome in the suite of Charles V. For some time he held a position in the papal court at Rome, but about 1534 he returned to France, and becoming an advocate, his
LIAO-YANG—LIAS

LIAO-YANG, a city of China, formerly the chief town of the province of Liao-tung or Sheng-kings (southern Manchuria), 35 m. S. of Mukden. It is situated in a rich cotton district in the fertile valley of the Liao, on the road between Niuchwang and Mukden, and carries on a considerable trade. The walls include an area about 2½ m. long by 2 m. broad, and there are fairly extensive suburbs; but a good deal even of the enclosed area is under cultivation. The population is estimated at 100,000.

Liao-yang was one of the first objectives of the Japanese during the Russo-Japanese War, and its capture by them resulted in some of the fiercest fighting during the campaign, from the 24th of August to the 4th of September 1904.

Lias, in geology, the lowest member of the Jurassic strata. Originally the name seems to have been written "Lyas"; it is most probably a provincial form of "layers," strata, employed by quarrymen in the west of England; it has been suggested, however, that the Fr. lias, Breton leach = a stone, Gaelic leac = a flat stone, may have given rise to the English "Lias." Lias strata occupy an important position in England, where they crop out at Lyme Regis on the Dorsetshire coast and extend thence by Bath, along the western flank of the Cotswold Hills, forming Edge Hill and appearing at Banbury, Rugby, Melton, Grantham, Lincoln, to Redcar on the coast of Yorkshire. They occur also in Glengarryshire, Shropshire, near Carlisle, in Skye, Raasay (Pabba, Scalpa and Broadfoot beds), and elsewhere in the north of Scotland, and in the north-east of Ireland. East of the belt of outcrop indicated, the Lias is known to occur beneath the younger rocks for some distance farther east, but it is absent from beneath London, Reading, Ware, Harwich, Dover, and in the southern portion of the area in which these towns lie; the Liasic fossils are probably thinned out against a concealed ridge of more ancient rocks. The table on following page will serve to illustrate the general characters of the English Lias and the subdivisions adopted by the Geological Survey. By the side are shown the principal ammonites, and, for comparison, the subdivisions preferred by Mr. M. J. Head of the Cambridge University Museum. The important fact is clearly demonstrated in the table, that where the Lias is seen in contact with the Trias below or the Inferior Oolite above, there is, as a rule, a gradual passage from the Liasic formation, both downwards and upwards; hence Professor de Lapport presents the zone of Ammonites opalinus at the top, and the Rhaetic beds at the bottom (see OOLITE; RAETIC). Owing to the transgression of the Liasic sea the strata rest in places upon older Palaeozoic rocks. The thickness of the Lias varies considerably; in Dorsetshire it is 900 ft., near Bath it has thinned to 280 ft., and beneath Oxford it is further reduced. In north Gloucestershire it is 1300 ft., Northampton 760 ft., Rutland 880 ft., Lincolnshire 950 ft., and in Yorkshire about 900 ft.

The Lias of England was laid down in conditions very similar to those which obtained at the same time in north France and north Germany, that is to say, on the floor of a shallow sea; but the Lias beds of America are developed upon a much greater scale. Many of the limestones are red and crystalline marbles such as the "ammonitico-rosso-inferiore" of the Apennines; a grey, laminated limestone is known as the "Fleckenmergel." The whitish "Hierlatzkalk," the Adnet beds and the "Grestener beds" in the eastern Alps and Balkan Mountains are important phases of Alpine Lias. The Grestener beds contain a considerable amount of coal. The Lias of Spain and the Pyrenees contains much dolomitic limestone. This formation is widely spread in western Europe; besides the localities already cited it occurs in Swabia, the Rhenish provinces, Alsace-Lorraine, Luxemburg, Ardenes, Normandy, Austria-Hungary, the Balkan States, Greece and Scania. It has not been found north of Kharkov in Russia, but it is present in the south and in the Caucasus, in Anatolia, Persia and the Himalayas. It appears on the eastern side of Japan, in Borneo, Timor, New Caledonia and New Zealand; in Alabama, Texas, and elsewhere in North Africa, and on the west coast of Madagascar. In South America it is found in the Bolivian Andes, in Chile and Argentina; it appears also on the Pacific coast of North America.
LIBANIUS—LIBAU

The economic products of the Lias are of considerable importance. In the Lower Lias of Lincolnshire and the Middle Lias of Oxfordshire, Northamptonshire, Lincolnshire, Leicestershire and Yorkshire the beds of ironstone are of great value. Most of these ores are limestones that have been converted into iron carbonate with some admixture of silicates; they weather near the surface into hydrated peroxide.

He removed his school to Nicomedia, where he remained five years. After another attempt to settle in Constantinople, he finally retired to Antioch (154). Though a pagan, he enjoyed the favour of the Christian emperors. When Julian, his special patron, restored paganism as the state religion, Libanius showed no intolerance. Among his pupils he numbered John Chrysostom, Basil (bishop of Caesarea) and Ammianus Marcellinus. His works, consisting chiefly of orations (including his autobiography), declamations on set topics, letters, life of Demostenes, and arguments to all his orations are voluminous. He devoted much time to the classical Greek writers, and had a thorough contempt for Rome and all things Roman. His speeches and letters throw considerable light on the political and literary history of the age. The letters number 1607 in the Greek original; with these were formerly included some 400 in Latin, purporting to be a translation, but now proved to be a forgery by the Italian humanist F. Zambecari (15th century).

At Frodingham in Lincolnshire the oolitic iron ore reaches 30 ft. in thickness, of which 12 ft. are workable. In Gloucestershire the top beds of the Lower Lias and lower beds of the Middle division are the most ferruginous. The most important districts are near Market Harborough and Leicester are at the summit of the Middle Lias in the Marlstone or Rock bed. The ironstone of Fawler is sometimes known as Blenheim ore. The ores of the Cleveland district in Yorkshire have a great reputation; the main ironstone is 11 ft. thick at Eston, where it rests directly upon the Pecten Seam, the two together aggregating 15 ft. 6 in. Similar iron ores of this age are worked at Meurthe-et-Moselle, Villerupt, Marlbeche, Longuy, Champlagneuelles, &c. Some of the Lias limestones are used in building stones. The more important ones being the Lower Lias Sutton stone of Glamorganshire and Middle Lias Hornton stone, the best of the Lias building stones, from Edge Hill. The limestones are often used for paving. The limestones of the Lower Lias are much used for the production of hydraulic cement and "Blue Lias" lime at Rugby, Barrow-on-Soar, Barnton, Lyme Regis, Abbertham and many other places. Roman cement made from the nodules in the Upper Lias of Yorkshire, alum is obtained from the same horizon. A considerable trade was formerly done in jet, the best quality being obtained from the "Serpentinus" beds, but "bastard" or soft jet is found in many of the other strata in the Yorkshire Lias. Both Lower and Upper Lias clays have been used in making bricks and tiles.

Fossils are abundant in the Lias; Lyme Regis, Shepton Mallet, Rugby, Robin Hood's Bay, Ilminster, Whirley and Golden Cap near Charmouth are well-known localities. The seartic reptiles, Ichthyosaurus and Plesiosaurus, are found in excellent preservation along with the Pterodactyl. Among the fishes are Hybodus, Dapedius, Pholidophorus, Acrodus. The crinoids, Pentacrinites and Eocrinites are locally abundant. Insect remains are very abundant in certain beds. Many of them occur in this formation in addition to the forms used as zonal indexes mentioned in the table. Limpia gigantea, Podosponya bromi, Inoceramus dubius, Glyphaea cubana, and G. orcutti are common pelecypods. Pseudolithodes laevis, Plioceras angulatus, Lepidopus, Spiriferina, Temperula, and Rhychnoclava are the brachiopods.

Cement dark limestones with regular bedding which occur in the Carboniferous System are sometimes called "Black Lias" by quarrymen. See "The Lias of England and Wales" (Yorkshire excepted), by H. B. Woodward, Geol. Survey Memoir (London, 1903); and, for Yorkshire, "The Jurassic Rocks of Britain," vol. i, by C. Fox-Strangways, Geol. Survey Memoir. See also JURASSIC (J. A. H.).

Libanius (A.D. 314-393), Greek sophist and rhetorician, was born at Antioch, the capital of Syria. He studied at Athens, and spent most of his earlier manhood in Constantinople and Nicomedia. His private classes at Constantinople were much more popular than those of the public professors, who had him expelled in 346 (or earlier) on the charge of studying magic.

LIBAU (Lebti, Lebttaya), a seaport of Russia, in the government of Courland, 145 m. by rail S.W. of Riga, at the northern extremity of a narrow sandy peninsula which separates Lake Libau (12 m. long and 2 m. wide) from the Baltic Sea. Its population has more than doubled since 1881 (30,000), being 64,505 in 1897. The town is well built of stone, with good gardens, and has a naval cathedral (1903). The harbour was
LIBEL AND SLANDER

535

2 m. S. of the town until a canal was dug through the peninsula in 1857; it is now deepened to 2 ft., and is mostly free from ice throughout the year. Since being brought, in 1872, into railway connexion with Moscow, Orel and Kharkov, Libau has become an important port. New Libau possesses large factories for colours, explosives, machinery, girds, and ropes, tobacco, furniture, matches, as well as iron works, agricultural machinery works, tin-plate works, soap works, saw-mills, breweries, oilmills, cork and linoleum factories and flour-mills. The exports reach the annual value of £3,250,000 to £5,500,000, oats being the chief export, with flour, wheat, rye, butter, eggs, spirits, flax, linseed, oilcake, pork, timber, horses and petroleum. The imports average £1,500,000 to £2,000,000 annually. Shipbuilding, including steamers for open sea-navigation, is on the increase. North of the commercial harbour and enclosing it the Russian government made (1833-1896) a very extensive fortified naval port, protected by mole and breakwaters. Libau is visited for sea-bathing in summer.

The port of Libau, Lüba portus, is mentioned as early as 1263; it then belonged to the Livonian Order or Brothers of the Sword. In 1418 it was burnt by the Lithuanians, and in 1560 it was mortgaged by the grandmaster of the Teutonic Order, to which it had passed, to the Prussian duke Albert. In 1701 it was captured by Charles XII of Sweden, and was annexed to Russia in 1795.

See Wegner, Geschichte der Stadt Libau (Libau, 1898).

LIBEL and SLANDER, the terms employed in English law to denote injurious attacks upon a man's reputation or character by words written or spoken, or by equivalent signs. In most early systems of law verbal injuries are treated as a criminal or quasi-criminal offence, the essence of the injury lying not in pecuniary loss, which may be compensated by damages, but in the personal insult which must be atoned for—a vindictive penalty coming in the place of personal revenge. By the law of the XII. Tables, the composition of scurrilous songs and gross sacrilegious public affronts were punished by death. Minor offences of the same class seem to have found their place under the general conception of injuria, which included ultimately every form of direct personal aggression which involved contumely or insult. In the later Roman jurisprudence, which has, on this point, exercised considerable influence over modern systems of law, verbal injuries are dealt with in the edict under two heads. The first comprehended defamatory and injurious statements made in a public manner (convicium contra bonos mores). In this case the essence of the offence lay in the unwarrantable public proclamation. In such a case the truth of the statements was no justification for the unnecessarily public and insulting manner in which they had been made. The second head included defamatory statements made in private, and in this case the offence lay in the imputation itself, not in the manner of its publication. The truth was therefore a sufficient defence, for no man had a right to demand legal protection for a false reputation when the true belief in the truth was enough, because it took away the intention which was essential to the notion of injuria. The law thus aimed at giving sufficient scope for the discussion of a man's character, while it protected him from needless insult and pain. The remedy for verbal injuries was long confined to a civil action for a money penalty, which was estimated according to the gravity of the case, and which, although vindictive in its character, doubtless included practically the element of compensation. But a new remedy was introduced with the extension of the criminal law, under which many kinds of defamation were punished with great severity. At the same time increased importance attached to the publication of defamatory books and writings, the libri or libelli famosi, from which we derive our modern use of the word libel; and under the later emperors the latter term came to be specially applied to anonymous accusations or pasquils, the dissemination of which was regarded as peculiarly dangerous, and visited with very severe punishment, whether the matter contained in them were true or false.

The earlier history of the English law of defamation is some-
contempt or ridicule. In one of the leading cases, for example, the plaintiff obtained damages because it was said of him that he was a hypocrite, and had used the clew of religion for unworthy purposes. In another case, a charge of ingratitude was sufficient. In civil cases the libel must be published by being brought by the defendant under the notice of a third party; it has been held that it is sufficient if this has been done by gross carelessness, without deliberate intention to publish. Every person is liable to an action who is concerned in the publication of a libel, whether he be the author, printer or publisher; and the extent and manner of the publication, although not affecting the ground of the action, is a material element in estimating the damages.

It is not necessary that the defamatory character of the words or writing complained of should be apparent on their face. They may be couched in the form of an insinuation, or may derive their sting from a reference to circumstances understood by the persons to whom they are addressed. In such a case the plaintiff must make the injurious sense clear by an averment joined, and it is for the jury to say whether the words borne the meaning thus ascribed to them.

In civil cases actions for slander and libel the falsity of the injurious statement is an essential element, so that the defendant is always entitled to justify his statements by their truth; but when the statements are in themselves defamatory, their falsity is presumed, and the burden of proving their truth is laid upon the defendant. There are however a large class of false defamatory statements, commonly called privileged, which are not actionable on account of the particular circumstances in which they are made. The general theory of law with regard to these cases is this. It is assumed that in every case of defamation intention is a necessary element; but in the ordinary case, when a statement is false and defamatory, the law presumes that it has been made or published with an evil intent, and will not allow this presumption to be rebutted by evidence or submitted as matter of fact to a jury. But there are certain circumstances in which the natural presumption is quite the other way. There are certain natural and proper occasions on which statements may be made which are in themselves defamatory, and which may be false, but which naturally suggest that the statements may have been made from a perfectly proper motive and with entire belief in their truth. In the cases of the kind which are recognized by law, the presumption is reversed. It lies with the plaintiff to show that the defendant was actuated by what is called express malice, by an intention to do harm, and in this case the question is not one of legal inference for the court, but a matter of fact to be decided by the jury. Although, however, the theory of the law seems to rest entirely upon natural presumption of intention, it is pretty clear that in determining the limits of privilege the courts have been almost wholly guided by considerations of public or general expediency.

In some cases the privilege is absolute, so that we cannot have an action for defamation even although we prove express malice. Thus no action of this kind can be maintained for statements made in judicial proceedings if the defendant is in any sense relevant to the trial. In the same way no statements or publications are actionable which are made in the ordinary course of parliamentary proceedings. Papers published under the authority of parliament are protected by a special act, 3 & 4 Vict. c. 9, 1840, which was passed after a decree of the law courts adverse to the privilege claimed. The reports of judicial and parliamentary proceedings stand in a somewhat different position, which has only been attained after a long and interesting conflict. The general rule now is that all reports of parliamentary or judicial proceedings are privileged so far as they are honest and impartial. Even ex parte proceedings, in so far as they take place in public, now fall within the same rule. But if the report is garbled, or if part of it only is published, the party who is injured in consequence is entitled to maintain an action, and to have the question of malice submitted to a jury.

Both absolute and qualified privilege are given to newspaper reports under certain conditions by the Law of Libel Amendment Act 1888. The reports must, however, be published in a newspaper as defined in the Newspaper Libel and Registration Act 1881. Under this act a newspaper must be published "at intervals not exceeding twenty-six days."

By s. 3 of the act of 1888 fair and accurate reports of judicial proceedings are absolutely privileged provided that the report is published contemporaneously with the proceedings and no blasphemous or indecent matter is contained therein. By s. 4 a limited privilege is given to reports of debates in public parliaments and legislative councils, school board, board of guardians, board of local authority, constituted under the provisions of any act of parliament, or of any committee appointed by any of these bodies; or of any meeting of interest held or conducted by any such committee, or by any newspaper proprietor, publisher or editor unless the order of a judge at chambers has been first obtained. This protection does not cover the actual writer of the alleged libel.

In private life a large number of statements are privileged so long as they remain matters of strictly private communication. It is difficult to define the limits of this privilege. Without making any reference to concrete cases; but generally it may be said that it includes all communications made in performance of a duty not merely legal but moral or social, answers to bona fide inquiries, communications made by persons in confidential relations regarding matters in which one or both are interested, and even statements made within proper limits by persons in the bona fide prosecution of their own interest. Common examples of this kind of privilege are to be found in answer to inquiries as to the character of servants or the solvency of a trader, warthing to a friend, communications between persons who are jointly interested in some matters of business. But in every case care must be taken not to exceed the limits of publication required by the occasion, or otherwise the privilege is lost. Thus defamatory statements may be privileged when made to a meeting of shareholders, but not when published to others who have no immediate concern in the business.

In a few instances in which an action cannot be maintained even by the averment of malice, the plaintiff may maintain an action by averring not only malice but also want of reasonable and probable cause. The most common instances of this kind are malicious charges made in the ordinary course of justice and malicious prosecutions. In such cases it would be contrary to public policy to punish or prevent every charge which was made from a purely malicious motive, but there is no reason for protecting accusations which are not only malicious, but destitute of all reasonable probability.

Criminal Law.—Publications which are blasphemous, immoral or seditory are frequently termed libels, and are punishable both at common law and by various statutes. The matter, however, which constitutes the offence in these publications lies beyond our present scope. Libels upon individuals may be prosecuted by criminal information or indictment, but there can be no criminal prosecution for slander. So far as concerns the definition of libel, and its limitation by the necessity of proving in certain cases express malice, there is no substantial difference between the rules which apply to criminal prosecutions and to
civil actions, with the one important exception (now considerably modified) that the falsity of a libel is not in criminal law an essential element of the offence. If the matter alleged in itself defamatory, the court would not permit inquiry into its truth. The sweeping application of this rule seems chiefly due to the indiscriminate use, in earlier cases, of a rule in Roman law which was only applicable to certain modes of publication, but has been supported by various reasons of general policy, and especially by the view that one main reason for punishing a libel was its tendency to provoke a breach of the peace.

An important dispute about the powers of the jury in cases of libel arose during the 19th century in connexion with some well-known trials for seditious libels. The point is familiar to readers of Macauley in connexion with the trial of the seven bishops, but the cases in which it was brought most prominently forward, and which led to its final settlement, were those against Woodfall (the printer of Juntas), Wilkes and others, and especially the case against Shipley, the dean of St Asaph (21 St. Tr. 925), in which the question was fought by Lord Erskine with extraordinary energy and ability. The controversy turned upon the question whether the jury were to be strictly confined to matters of fact which required to be proved by evidence, or whether in every case they were entitled to form their own opinion upon the libellous character of the publication and the intention of the author. The jury, if they pleased, had it in their power to return a general verdict of guilty or not guilty, but both in theory and practice they were subject in law to the directions of the court, and had to be informed by it as to what they were to take into consideration in determining upon their verdict. There is no difficulty about the general application of this principle in criminal trials. If the crime is one which is inferred by law from certain facts, the jury are only concerned with these facts, and must accept the construction put upon them by law. Applying these principles to the libellous character of publication, it is clear that it was for the court to determine whether the publication fell within the definition of libel, and whether the case was one in which malice was to be inferred by construction of law. If the case were one in which malice was inferred by law, the only facts left to the jury were the fact of publication and the meaning averred by innuendoes; they could not go into the question of intention, unless the case were one of privilege, in which express malice had to be proved. In general principle, therefore, the decisions of the court were in accordance with the ordinary principles of criminal law. But there were undoubtedly some peculiarities in the case of libel. The sense of words, the inferences to be drawn from them, and the effect which they produce are not so easily defined as gross matters of fact. They seem to belong to those cases in which the impression made upon a jury is more to be trusted than the decision of a judge. Further, owing to the mode of procedure, the defendant was often punished before the question of law was determined. But, nevertheless, the question would scarcely have been raised had the libels related merely to private matters. The real ground of dispute was the liberty to be accorded to political discussion. Had the judges taken as wide a view of privilege in discussing matters of public interest as they do now, the question could scarcely have arisen; for Erskine's whole contention really amounted to this, that the jury were entitled to take into consideration the good or bad intent of the authors, which is precisely the question which would now be put before them in any matter which concerned the public. But at that time the notion of a special privilege attaching to political discussion had scarcely arisen, or was confined within very narrow limits, and the cause of free political discussion seemed to be more safely entrusted to juries than to courts. The question was finally settled by the Libel Act 1702, by which the jury were entitled to give a general verdict on the whole matter, not in issue, which was originally decided with the offender by public retrial or penalty, but subsequently made use of fines payable to their own prosecutor or to the party injured, these latter being regarded as solutum to his feelings; or, lastly, an action of damages was competent before the court of session, which was strictly civil in its character and aimed at the reparation of patrimonial loss. The first remedy is almost self-obvious; the second, which (as in Roman law, the truth would be a defence) is never related to the jury, but the criminal remedy, is that which has been in most use. The amount of the fine, which has been up to the present time paid to the injured person, or his assigns, or in default to the clerk of session, is sufficient to make the practice strictly civil, and to give it that mode of proceeding which it has been described as having in the nature of a penalty.

Scots Law.—In Scots law there were originally three remedies for defamation. It might be prosecuted by or with the concurrence of the lord advocate before the court ofjusticiary; or, secondly, a criminal remedy might be obtained in the ecclesiastical courts, which, originally designed for the offender by public retrial or penalty, but subsequently made use of fines payable to their own
Liber and Libera—Liber Romanorum Pontificum

8 by 3 in., the latter on mere fragments of papyrus which have been pieced together. The former was first deciphered and described by Dr Fritz Krebs, the latter by Dr K. Wessely; both are given and commented upon by Dr Benson. There is a remarkable similarity between them; in each the form is that of N. "was ever constant in sacrificing to the gods"; and that he now, in the presence of the commissioners of the sacrifices (οἱ ἤρμενα τῶν θεῶν), has both sacrificed and drunk [or has poured libations], and has tasted of the victims, in witness whereof he begs them to sign this certificate. Then follows the signature, with attestations. The former of the two is dated, and the date must fall in the year 230. It is impossible to prove that either of the documents actually refers to Christians: they may have been given to pagans who had been accused and had cleared themselves, or to former Christians who had apostatized. But no doubt libelli in this same form were delivered, in Egypt at least, to Christians who secured immunity without actual apostasy; and the form in Ethiopia and Africa probably did not differ widely from this. The practice gave rise to complicated problems of ecclesiastical discipline, which are reflected in the correspondence of Cyprian and especially in the Novatian controversy.

See E. W. Benson, Cyprian (London, 1897); Theol. Literaturzeitschrift, 20th of January and 17th of March 1894. (W. E. Co.)

Liber and Libera, in Roman mythology, deities, male and female, identified with the Greek Dionysus and Persephone. In honour of Liber (also called Liber Pater and Bacchus) two festivals were celebrated. In the country feast of the vintage, held at the time of the gathering of the grapes, and the city festival of March 17th called Liberalia (Ovid, Fasti, iii. 711) we find purely Italian ceremonial unaffected by Greek religion. The country festival was a great merry-making, where the first-fruits of the new vines were offered to the gods. It was characterized by the grossest sensualism, in honour of the fertility of nature. In the city festival, growing civilization had impressed a new character on the primitive religion, and connected it with the framework of society. At this time the youths laid aside the boy's toga praetexta and assumed the man's toga libera or virilis (Fasti, iii. 711). Cakes of meal, honey and oil were offered to the two deities at this festival. Liber was originally an old Italian god of the productivity of nature, especially of the vine. His name indicated the free, unrestrained character of his worship. When, at an early period, the Hellenic religion of Demeter spread to Rome, Liber and Libera were identified with Dionysus and Persephone, and associated with another Italian goddess Ceres, who was identified with Demeter. By order of the Sybil's books, a temple was built to these three deities near the Circus Flaminius; the whole cultus was borrowed from the Greeks, down even to the terminology, and priestesses were brought from the Greek cities.

Liberal Party, in Great Britain, the name given to and accepted by the successors of the old Whig party (see Whig and Tory), representing the political party opposed to Toryism or Conservatism, and claiming to be the originators and champions of political reform and progressive legislation. The term came into general use definitely as the name of one of the two great parties in the state when Mr Gladstone became its leader, but before this it had already become current coin, as a political appellation, through a natural association with the use of such phrases as "liberal ideas," in the sense of "favourable to change," or "in support of political freedom and democracy." In this respect it was the outcome of the French Revolution, and in the early years of the 19th century the term was used in a French form; thus Southey in 1816 wrote about the "British Liberals." But the Reform Act and the work of Bentham and the Luddites were due to the crystallization of the term. In Leigh Hunt's autobiography (1859) he remarks of the younger and more thoroughgoing Whigs "known by the name of Radicals; [...] called Liberals"; and J. S. Mill in 1865 wrote (from his own Liberal point of view), "A Liber is he who looks forward for his principles of government; a Tory looks backward." The gradual adoption of the term for one of the great parties, succeeding "Whig," was helped by the transition period of "Liberal Conservation," describing the position of the later Peelites; and Mr Gladstone's own career is the best instance of its changing specification; moreover the adjective "liberal" came meanwhile to be used in other sphears than that of parliamentary politics, e.g. in religious controversies "intellectually advanced" and free from the trammels of tradition. Broadly speaking, the Liberal party stands for progressive legislation in accordance with freedom of social development and advanced ethical ideas. It claims to represent government by the people, by means of trust in the people, in a sense which denies genuine popular sympathy to its opponents. Being largely composed of dissenters, it has identified itself with opposition to the vested interests of the Church of England; and, being apt to be thwarted by the House of Lords, with attempts to override the veto of that house. Its old watchword, "Peace, retrenchment and reform," indicated its tendency to avoidance of a "spiritual" foreign policy, and to parsimony in expenditure. But throughout its career the Liberal party has always been pushed forward by its extreme Radical wing, and economy in the spending of public money is no longer cherished by those who chiefly represent the non-taxpaying classes. The party organization lends itself to the influence of the times. In 1795 the central organization was started in the Liberal Registration Association, composed "of gentlemen of known Liberal opinions"; and a number of "Liberal Associations" soon rose throughout the country. Of these, that at Birmingham became, under Mr J. Chamberlain and his active supporter Mr Schnadhorst, particularly active in the seventies; and it was due to Mr Schnadhorst that in 1877 a conference was held at Birmingham which resulted in the formation of the "National Federation of Liberal Associations," or "National Liberal Federation," representing a system of organization which was dubbed by Lord Beaconsfield "the Caucus." The Birmingham Caucus and the Central Liberal Association thus coexisted, the first as an independent democratic institution, the second as the official body representing the whips of the party, the first more advanced and "Radical," the second inclined to Whiggishness. Friction naturally resulted, but the 1880 elections confirmed the success of the Caucus and consolidated its power. And in spite of the Home Rule crisis in 1886, resulting in the splitting off of the Liberal Unionists—"dissentent Liberals," as Mr Gladstone called them—from the Liberal party, the organization of the National Liberal Federation remained, in the dark days of the party, its main support. Its headquarters were, however, removed to London, and under Mr Schnadhorst it was practically amalgamated with the old Central Association.

It is impossible here to write in detail the later history of the Liberal party, but the salient facts will be found in such articles as those on Mr Gladstone, Mr J. Chamberlain, Lord Roscberry, Sir Henry Campbell-Bannerman, Mr H. H. Asquith and Mr David Lloyd George.

Liber Diurnus Romanorum Pontificum, or "Journal of the Roman Pontiffs," the name given to a collection of formulae used in the papal chancery in preparing official documents, such as the installation of a pope, the bestowal of the pallium and the grant of papal privileges. It was compiled between 685 and 751, and was constantly employed until the 12th century, when, owing to the changed circumstances of the Church, it fell into disuse, and was soon forgotten and lost. During the 17th century a manuscript of the Liber was discovered in Rome by the humanist, Lucas Holstenius, who prepared an edition for publication; for politic reasons, however, the publication would not allow this to appear, as the book asserted the superiority of a general council over the pope. It was, however, published in France by the Jesuit, Jean Garnier, in 1680, and other editions quickly followed.

The best modern editions are one by Eugène de Rolzière (Paris, 1869) and another by T. E. von Sichel (Vienna, 1890), both of which contain critical introductions. The two existing manuscripts of the Liber are in the Vatican library, Rome, and in the library of St Ambrose at Milan.
LIBERIA, a negro republic in West Africa, extending along
the coast of northern Guinea about 300 m., between the British
colony of Sierra Leone on the N.W. and the French colony of
the Ivory Coast on the S.E. The westernmost point of Liberia (at
the mouth of the river Mano) lies in about 6° 55' N. and 11°
32' W. The southernmost point of Liberia, and at the same
time almost its most eastern extension, is at the mouth of the Cavalla,
beyond Cape Palmas, only 4° 29' N. of the equator, and in about
7° 33' W. The width of Liberia inland varies very considerably;
it is greatest, about 200 m., from N.E. to S.W. The Liberia-Sierra
Leone boundary was determined by a frontier commission in
1903. Commencing at the mouth of the river Mano, it follows
the Mano up stream till that river cuts 10° 40' W. It then
followed this line of longitude to its intersection with N. latitude
6° 0', but by the Franco-Liberian understanding of 1906 the
boundary was drawn to 8° 25' N., where the river
Makona crosses 10° 40' W. The Liberian frontier with the
adjacent French possessions was defined by the Franco-Liberian
treaty of 1892, but as the definition therein given was found
to be very difficult of reconciliation with geographical features
(for in 1892 the whole of the Liberian interior was unmapped)
further negotiations were set on foot. In 1905 Liberia proposed
to France that the boundary line should follow the river Moa
from the British frontier of Sierra Leone up stream to near the
source of the Moa (or Makona), and that from this point the
boundary should run eastwards along the line of water-parting
between the system of the Niger on the north and that of the
coast rivers (Moa, Lofo, St Paul's) on the south, until the 8th
degree of N. latitude was reached, then south, following the
coast line eastwards to where it cuts the head stream of the Cavalla
river. From this point the boundary between France and Liberia
would be the course of the Cavalla river from near its source to
the sea. Within the limits above described Liberia would
possess a total area of about 43,000 to 45,000 sq. m. But after
deliberation and as the result of certain "frontier incidents"
France modified her counter-proposals in 1907, and the actual
definition of the northern and eastern frontiers of Liberia is as
follows:-

Starting from the point on the frontier of the British colony
of Sierra Leone where the river Moa or Makona crosses that frontier,
the Franco-Liberian frontier shall follow the left bank of the river
Makona up stream to a point 5 kilometres to the south of the town
of Bolosso. From this point the frontier shall leave the line of the
Makona and be carried in a south-easterly direction to the mouth of
the Lofa river (or Western Cavalla). This line shall be so drawn as to leave on the French side
of the boundary the following towns: Kutumai, Kis Kurumai,
Sundlo, Zzopa, Nziha, Kolinam, Bangwedoo and Lofa. As this lower boundary shall follow
the right bank of the said Nono river down stream to its presumed confluence with the Cavalla, and thenceforward the right bank of the river
Lofa shall be the boundary of the territory of Liberia, the right hand side of the river being
that of the Nono. The right bank of the Nono river shall be the boundary between Salvador
and the territory of Liberia. The Nono river is the river which flows from the Sila range of
mountains. It is joined by a considerable stream from the south, and the river from the north
of the Sila range. The river flows down through the territory of Liberia to the sea, and enters
the sea under the name of the river Dinara (Portuguese, Dundera).

It is at the southern extremity of Liberia, Cape Palmas, that
the West African coast from Morocco to the southernmost
extremity of Guinea turns somewhat abruptly eastwards and
northwards and faces the Gulf of Guinea. As the whole coastline
of Liberia thus fronts the sea route from Europe to South Africa
it is always likely to possess a certain degree of strategical
importance. The coast, however, is unprovided with a single
good harbour. The anchorage at Monrovia is safe, and with
some expenditure of money a smooth harbour could be made in
front of Grand Bassa.

Coast Features.—The coast is a good deal indented, almost all the
headlands projecting from north-east to south-west. A good deal
of the seacoast is dangerous by reason of the sharp rocks which lie
near the surface. As most of the rivers have rapids or falls actually
at the sea coast or close to it, they are, with the exception of the
principal, unsuitable for navigation. For practically all purposes
this part of Africa from Cape Palmas north-west to the Senegal suggests
a sunken land. In all probability the western projection of Africa
was connected by a land bridge with the opposite land of Brazil
and the western coast of the late Guinean and Colofanian territories.
The eastern coast has few lagoons compared with the adjoining littoral of Sierra
Leone or that of the Ivory Coast. The coast, in fact, rises in some
places rather abruptly from the sea. Cape Mount (on the northern
side of the mouth of the river Cavalla) is said to be little more than a
cliff, and the coast farther west is actually swampy, a kind of natural
canalization connects many of the rivers at their mouths with each other, though some of these connecting creeks are as yet
unmarked on maps.

Although there are patches of marsh—generally the swampy bottoms of valleys—the whole surface of Liberia inclines to be hilly or even mountainous at a short distance inland from the coast. In the north-east, French explorers have computed the altitudes of some mountains at figures which would make them the highest land surfaces of the western projection of Africa—from 6000 to 9000 ft. But these altitudes are largely matters of conjecture.
The same mountains have been sighted by English explorers coming from the south and by Frenchmen from the north. It is possible that they may reach to 6000 ft. in some places. Between the western bend of the Cavalla river and the coast there is a somewhat
broken mountain range with altitudes of from 2000 to 5000 ft.

The mountains to the west of the St Paul's river may
reach in places to 3000 ft.

Rivers.—The work of the Franco-Liberian delimitation commission
in 1908–9 cleared up many points connected with the hydro-
graphy of the country. Notably it traced the upper Cavalla, proving
that that river was not connected either with the Nono on the west or
the Ko or Zo on the east. The upper river and the left bank of
the lower river of the Cavalla are in French territory. It rises
in about 7° 50' N., 9° 30' W. in the Nimba mountains, where also rise
the Nono, St John's and Dukwa rivers. After flowing S.E., the
Cavalla, between 7° and 8° N., under the name of Dugu, makes a
very considerable elbow to the west until the mouth of the south-west
arm of the river. It is navigable from the sea for some 80 m. from
its mouth and after a long series of rapids is again navigable.

Unfortunately the Cavalla does not afford a means of easy penetration
in the shallow, uncharted lagoons which separate it from the
inland. The Nono (or Nipwe) river, which up to 1908 was described
sometimes as the western Cavalla and sometimes as the upper course of the
St John's river, has been shown to be the upper course of the
Cavalla. The Nono rises in the Nimba range of mountains, 10 m. S.
of the source of the Cavalla, and like all the Liberian rivers (except the Cavalla) it has a
general S.E. flow. The St Paul, though inferior to the Cavalla in
its general character, has the same direction of flow of the Nono.
The main branch rises in the Bella country nearly as far north as 9°
N. under the name of Dibani. Between 8° and 7° N. it is joined by the
Wé from the west and the Walé from the east. The important river
has a considerable left bank branch, about 30 m. from the sea,
and a right branch near the town of St Paul's river. The
Mamoror or Beva river rises in the dense Gora forest, but is of no
great importance until it becomes the frontier between Liberia and
Sierra Leone. The Dukwa and Farimong are torrent rivers, entering the sea under the name of the river Dunk (Portuguese,
Jusco). The Farimong is a short stream, but the Dukwa is believed
to be the lower course of the Mani, which rises as the Tigven or
Monimbi on the north of the Yuma and the north-east.

The St John's river of the Basa country appears to be of considerable
importance and volume. The Sino river rises in the Niete mountains
and brings down a great volume of water to the sea, though it is
not navigable. It is crossed by a considerable stream near the head
of the Satro mountains and flows nearly parallel with the Cavalla,
which it joins. The Moa or Makona is a fine stream of considerable
volume, but its course is perpetually interrupted by falls and
rapids. It runs through the territory of Sierra Leone, and it enters the sea as the Sulima.

Climate and Rainfall.—The climate of Liberia is almost everywhere well watered.
The climate as a whole is of the tropical type, and perhaps, about
120 m. land is equatorial, the rainfall in the western half of the
country being about 150 in. per annum and in the eastern half
about 100 in. North of a distance of about 120 m. inland the climate
is prone to be rainy, it is much cooler than the dry season.

This region beyond the hundredth meridian is still fair and
the forest good and agreeable to Europeans.

Forests.—Outside a coast belt of about 20 m. and south of 8° N.
there is not one valle in which the soil has been cleared for
salt for cultivation. In many districts the land has been cleared
and cultivated and then abandoned, and has relapsed into scrub
and jungle which is gradually returning to the condition of forest.

The densest forest of all would seem to be that known as Gora,
Liberia

which is almost entirely uninhabited and occupies an area of about 600 sq. m. between the Pô hills and the British frontier. There is another very dense forest stretching with little interruption from the eastern side of St Paul's river nearly to the Cavalla. The Nict forest is under the protection of a national park, and it is remarkable that within a short distance there are two large African pythons (P. sebae) and a rare Boine snake (Calabaria). On the sea coast there is the leathery termite (Dermochilus) and the green termite (Chelone). In the rivers and swamps there are many varieties of indigenous fish, and there are some of the lovely plumage, also the Kingfishers and the rails. There are two large African pythons (P. sebae) and a rare Boine snake (Calabaria). In the rivers and swamps there are many varieties of indigenous fish, and there are some of the lovely plumage, also the Kingfishers and the rails.

Liberia

The climate of Liberia is sufficiently peculiar, at any rate as regards vegeta- tions, to make it very nearly identical with a district or sub-province of the West African province, though in this case the Liberian district would not include the northernmost portions of the territory and would be the eastern part except into Sierra Leone and the French Ivory Coast. It is probable that the Liberian chimpanzee may offer one or more distinct varieties; there is an interesting local development of the Diana monkey, sometimes called the bay-chested monkey (Cercopithecus diana signa) on account of its brilliant orange-red thighs. One or more species of bats are peculiar to the country—Vesperilibus planifus, and possibly Rossoussensus billi—two species of shrew (Cricetulus), and possibly a species of the genus Affinis (H. liberiensis)—differing from the common hippopotamus by its much smaller size and by the reduction of the incisor teeth to a single pair in each jaw, or occasionally to the number of three; and a rare species of the giant cat (Cephalophus jentinki), and the zebra antelope, C. dora, Ic., a creature the size of a small goat, of a bright yellow brown, with broad black zebra-like stripes, and with a long tail of almost identical pattern. There are two large otters: the hyrax, elephant and manati; the red bush pig (Potamochoerus porcus), the West African cheetah (Ourearchis), the Senegalese buffalo; Bongo antelope (Booceris); and the forest elephant (Elephas liberiensis) grey, black, and large, which is very much related to the African elephant, and has a very thick and sturdy build. There are also many varieties of indigenous fish, and there are some of the lovely plumage, also the Kingfishers and the rails.

The birds of Liberia are not so peculiar as the mammals. There are two species of the well-known guinea fowl, Agelastes, which are found on the Gold Coast and elsewhere west of the lower Niger; and there is a peculiar species of eagle owl (Bubo lepil) and a very handsome species of vulture (Aegypius). There are many varieties of the skunk (Bathier), and the scaly-tailed flying Anomalura; the common porcupine, the koud, serval, golden cat (Felis catulvaria) and the scarlet ibis, which are both abundant. The songs of the birds are a great variety and are as distinctive as the languages of the various tribes. The birds are noted for their brilliant plumage, and there are many varieties of indigenous fish, and there are some of the lovely plumage, also the Kingfishers and the rails.

Minerals—The hinterland of Liberia has been but slightly explored for mineral wealth. In general it is supposed that the resources of the country are not yet fully known, but what has been discovered are several localities of gold in the vicinity of river mouths. There are indications of tin and of copper in the district of the Cavalla, and there are indications of iron in the vicinity of the river mouths. The iron content is not yet fully known, but what has been discovered are several localities of gold in the vicinity of river mouths. There are indications of tin and of copper in the district of the Cavalla, and there are indications of iron in the vicinity of the river mouths.
History and Population.—Tradition asserts that the Liberian coast was first visited by Europeans when it was reached by the Dieppe merchant-adventurers in the 14th century. The French in the 17th century claimed that but for the loss of the archives of Dieppe they would be able to prove that vessels from this Norman port had established settlements at Grand Basa, Cape Mount, and other points on the coast of Liberia. No proof has yet been forthcoming, however, that the Portuguese were not the first white men to reach this coast. The first Portuguese pioneer was Pedro de Sintra, who discovered and noted in 1461 the remarkable promontory of Cape Mount, Cape Mesurado (where the capital, Monrovia, is now situated) and the mouth of the Junk river. In 1462 de Sintra returned with another Portuguese captain, Sueiro da Costa, and penetrated as far as Cape Palmas and the Cavalla river. Subsequently the Portuguese mapped the whole coast of Liberia, and nearly all the prominent features—capes, rivers, islets—of that coast still bear Portuguese names. From the 16th century onwards, English, Dutch, German, French and other European traders contested the commerce of this coast with the Portuguese, and finally drove them away. In the 18th century France once or twice thought of establishing colonies here. At this time the tide was rising in favour of the abolition of slavery and the repatriation of slaves, the Grain Coast [so called from the old trade in the "Grains of Paradise" or Anomum pepper] was suggested once or twice as a suitable home for repatriated negroes. Sierra Leone, however, was chosen first on account of its possessing an admirable harbour. But in 1821 Cape Mesurado was selected by the American Colonization Society as an appropriate site for the first detachment of American freed negroes, whom difficulties in regard to extending the suffrage in the United States were driving away from a still slave-holding America. From that date, 1821, onwards to the present day, negroes and mulattos—freed slaves or the descend-ants of such—have been crossing the Atlantic in small numbers to settle on the Liberian coast. The great migrations took place during the first half of the 19th century. Only two or three thousand American emigrants—at most—have come to Liberia since 1860.

The colony was really founded by Jehudi Ashmun, a white American, between 1822 and 1828. The name "Liberia" was invented by the Rev. R. R. Gurley in 1824. In 1847 the American colonists declared their country to be an independent republic, and its status in this capacity was recognized in 1848-1849 by most of the great powers with the exception of the United States. Until 1857 Liberia consisted of two republics—Liberia and Maryland. These American settlements were dotted at intervals along the coast from the mouth of the Sewa river on the west to the San Pedro river on the east (some 60 m. beyond Cape Palmas). Some tracts of territory, such as the greater part of the Kru coast, still, however, remain without foreign—American—settlers, and in a state of quasi-independence. The uncertainty of Liberian occupation led to frontier troubles with Great Britain and disputes with France. Finally, by the English and French treaties of 1885 and 1892 Liberian territory on the coast was made continuous, but was limited to the strip of about 300 m. between the Mano river on the west and the Cavalla river on the east. The Sierra Leone-Liberia frontier was demarcated in 1903; then followed the negotiations with France for the exact delimitation of the Ivory Coast-Liberia frontier, with the result that Liberia lost part of the hinterland she had claimed. Reports of territorial encroachments aroused much sympathy with Liberia in America and led in February 1909 to the appointment by President Roosevelt of a commission which visited Liberia in the summer of that year to investigate the condition of the country. As a result of the commissioners' report negotiations were set on foot for the adjustment of the Liberian debt and the placing of United States officials in charge of the Liberian customs. In July 1910 it was announced that the American government, acting in general agreement with Great Britain, France and Germany, would take charge of the finances, military organization, agriculture and boundary questions of the re-

1 Amongst other remarkable negroes that Liberian education produced was Dr E. W. Blyden (b. 1832), the author of many works dealing with negro questions.
LIBERIUS—LIBERTAD

although large areas appear to be uninhabited forest, other parts are most densely populated, owing to the wonderful fertility of the soil. The native tribes belong more or less to the following divisions, commencing on the west, and proceeding eastwards: (1) Vai, Gbandi, Kpwesi, Mende, Buzi and Mandingo (the Vai, Mende and Mandingo are Mahomedans); all these tribes speak languages derived from a common stock. (2) In the densest forest region between the Mano and the St Paul's river is the powerful Gora tribe of unknown linguistic affinities. (3) In the coast region between the St Paul's river and the Cavalla (and beyond) are the different tribes of Kru stock and language family—Dë, Basă, Gibi, Kru, Grebo, Putu, Sikoñ, &c. &c. The actual Kru tribe inhabits the coast between the river Cesos on the west and Grand Sesters on the east. It is known all over the Atlantic coasts of Africa, as it furnishes such a large proportion of the seamen employed on men-of-war and merchant ships in these tropic waters. Many of the indigenous races of Liberia in the forest belt beyond 40 m. from the coast still practise cannibalism. In some of these forest tribes the women still go quite naked, but clothes of a Mahommedan type are fast spreading over the whole country. Some of the indigenous races are of very fine physique. In the Nidi country the women are generally taller than the men. No traces of a Pygmy race have as yet been discovered, nor any negroes of low physiognomy. Some of the Krumen are coarse and ugly, and this is the case with the Mende people; but as a rule the indigens of Liberia are handsome, well-proportioned negroes, and some of the Mandingsos have an almost European cast of feature.

LIBERIUS, pope from 352 to 366, the successor of Julius I., was consecrated according to the Catalogus Liberianus on the 22nd of May. His first recorded act was, after a speech had been held at Rome, to write to Constantinian, then in quarters at Arles (353–354), asking that a council might be called at Aquileia with reference to the affairs of Athanasius; but his messenger Vincentius of Capua was commanded by the emperor at a concilium held at Arles to subscribe against his will a condemnation of the orthodox patriarch of Alexandria. In 355 Liberius was one of the few who, along with Eusebius of Vercelli, Dionysius of Milan and Lucifer of Cagliari, refused to sign the condemnation of Athanasius, which had anew been imposed at Milan by imperial command upon all the Western bishops; the consequence was his relegation to Beroea in Thrace, Felix II. (antipope) being consecrated his successor by three "catascopi haud episcopi," as Athanasius called them. At the end of an exile of more than two years he yielded so far as to subscribe a formula giving up the "Mariana," a work to abandon Athanasianism, and acknowledged the condemnation of his adversaries as a serious mistake, with which he has justly been reproached. This submission led the emperor to recall him from exile; but, as the Roman see was officially occupied by Felix, a year passed before Liberius was sent to Rome. It was the emperor's intention that Liberius should govern the Church jointly with Felix, but on the arrival of Liberius, Felix was expelled by the Roman people. Neither Liberius nor Felix took part in the council of Rimini (359). After the death of the emperor Constantius in 361, Liberius annulled the decrees of that assembly, but, with the concurrence of SS. Athanasius and Hilarius, retained the bishops who had signed and then withdrawn their adherence. In 366 Liberius gave a favourable reception to a deputation of the Eastern episcopate, and admitted into his communion the more moderate of the old Arián party. He died on the 24th of September 366.

His biographers used to be perplexed by a letter purporting to be from Liberius, in the works of Hilary, in which he seems to write, in 352, that he had excommunicated Athanasius at the instance of the Oriental bishops; but the document is now held to be spurious. See Hefele, Concilien. i. 648 seq. Three other letters, though contested by Hefele, seem to have been written by Liberius at the time of his submission to the emperor.

Liber Pontificalis, or Gesta Pontificum Romanorum (c. 850; the period), consists of the lives of the bishops of Rome from the time of St Peter to the death of Nicholas I. in 867. A supplement continues the series of lives almost to the close of the 9th century, and several other continuations were written later. During the 16th century there was some discussion about the authorship of the Liber, and for some time it was thought to be the work of an Italian monk, Anastasius Bibliothecarius (d. 886). It is now, however, practically certain that it was of composite authorship and that the earlier part of it was compiled about 530, three centuries before the time of Anastasius. This is the view taken by Louis Duchesne and substantially by G. Watzl and T. Mommsen, although these scholars think that it was written about a century later. The Liber contains much information about papal affairs in general, and about endowments, martyrdoms and the like, but a considerable part of it is obviously legendary. It assumes that the bishops of Rome exercised authority over the Christian church from its earliest days.

The Liber, which was used by Bede for his Historia Ecclesiastica, was first printed at Mainz in 1602. Among other editions is the one edited by T. Mommsen for the Monumenta Germaniae historica. Gesta Romanorum pontificum, Band i., but the best is the one by H. Guilhot, Gesta pontificum Romanorum (Paris, 1884–1892). See also the same writer's Étude sur le Liber pontificalis (Paris, 1877); and the article by A. Brackmann in Herzog-Hauck's Realencyklopädie, Band xi. (Leipzig, 1902).

LIBERTAD, or La Libertad, a coast department of Peru, bounded N. by Lambayeque and Cajamarca, E. by San Martin, S. by Ancash, W. and by the Pacific. Pop. (1906 estimate) 185,600; area 10,200 sq. m. Libertad formerly included the present department of Lambayeque. The Western Cordillera divides it into two nearly equal parts; the western consisting of a narrow, arid, sandy coast zone and the western slopes of the Cordillera broken into valleys by short mountain spurs, and the eastern a high inter-Andine valley lying between the Western and Central Cordilleras and traversed by the upper Maranon or Amazon, which at one point is less than 90 m. in a straight line from the Pacific coast. The coast region is traversed by several short streams, which are fed by the melting snows of the Cordillera and are extensively used for irrigation. These (the names also applying to their valleys) the Jequetepeque or Pacasmayo, in whose valley rice is an important product, the Chicama, in whose valley the sugar plantations are among the largest and best in Peru, the Moche, Viru, Chao and Santa; the last, with its northern tributary, the Tumbes, forms the southern boundary line of the department. The Santa Valley is also noted for its sugar plantations. Cotton is produced in several of these valleys, coffee in the Pacasmayo district, and cocoa on the mountain slopes about Huamachuco and Otuzco, at elevations of 3000 to 6000 ft. above sea-level. The upland regions, which have a moderate rainfall and a cool, healthy climate, are partly devoted to agriculture on a small scale (producing wheat, Indian corn, barley, potatoes, quinua, alfalfa, fruit and vegetables), partly to grazing and partly to mining. Cattle and sheep have been raised on the upland pastures of Libertad and Ancash since early colonial times, and the llama and alpaca were reared throughout this "sierra" country long before the Spanish conquest. Gold and silver mines are worked in the districts of Huamachuco, Otuzco and Pataz, and coal has been discovered in the Cocha district. The road into the interior of the northern tributary, the Chablas, forming the southern boundary line of the department, was completed in 1906, viz.: from Pacasmayo to Yónán (in Cajamarca) with a branch to Guadalupe, 60 m.; from Salaverry to Trujillo with its extension to Ascope, 47 m.; from Trujillo to Laredo, Galindo and Menocucho, 18½ m.; from Huanchaco to Roma, 25 m.; and from Chicama to Pampas, 18½ m. The principal ports are Pacasmayo and Salaverry, which have long iron piers built by the national government; Malabrigo, Huanchaco, Guáape and Chao are open roadsteads. The capital of the department is Trujillo. The other principal towns are San
LIBERTARIANISM

Pedro, Otuco, Huamachuco, Santiago de Chuco and Tuyabamba —all provincial capitals and important only through their mining interests, except San Pedro, which stands in the fertile district of the Jequetepeque. The population of Otuco (35 m. N.E. of Trujillo) was estimated to be about 4000 in 1866, that of Huamachuco (65 m. N.E. of Trujillo) being perhaps slightly less.

**LIBERTARIANISM** (from Lat. libertas, freedom), in ethics, the doctrine which maintains the freedom of the will, as opposed to necessitarianism or determinism. It has been held in various forms. In its extreme form it maintains that the individual is absolutely free to choose this or that action indifferently (the *liberum arbitrium indifferente*), but most libertarians admit that acquired tendencies, environment and the like, exercise a greater or less degree.

**LIBERTINES,** the nickname, rather than the name, given to various political and social parties. It is futile to deduce the name from the Libertines of Act vi. 9: these were "sons of freedom," for it is vain to make them citizens of an imaginary Libertum, or to substitute (with Beza) Libustines, in the sense of inhabitants of Libya. In a sense akin to the modern use of the term "libertine," i.e., a person who sets the rules of morality, &c., at defiance, the word seems first to have been applied, as a stigma, to Anabaptists in the Low Countries (Mark Pattison, *Essays,* ii. 38). It has become especially attached to the liberal party in Geneva, opposed to Calvin and carrying on the tradition of the Libertins in that city; but the term was never applied to them till after Calvin's death (F. W. Kamp-schulte, *Johann Calvin*). Calvin, who wrote against the "Libertins qui se nomment Spirituelz" (1549), never confused them with his political antagonists in Geneva, called Perrinistes from their leader Amadée Perrin. The objects of Calvin's polemic were the Anabaptists above mentioned, whose first obscure leader was Coppen of Lisle, followed by Quintin of Henegau, by whom and his disciples, Bertram des Moulins and Claude Perseval, the principles of the sect were disseminated in France. Quintin was put to death as a heretic at Tournai in 1546. His most notable follower was Antoine Pocquet, a native of Enghien, Bishop, priest and almoner (1540-1540), afterwards pensioner of the Queen of Navarre, who was a guest of Bucer at Strassburg (1543-1544) and died some time after 1560. Calvin (who had met Quintin in Paris) describes the doctrines he impugns as pantheistical and aniconian.

(À. Go.* )

**LIBERTINES, SYNAGOGUE OF THE,** a section of the Hellenistic Jews who attacked Stephen (Acts vi. 9). The passage reads, *τοὺς ἄνθρωπος καὶ Ἀλέξανδρον καὶ Κυμαμωναὶ καὶ Σεβαστίου.* The name is derived from Σεβαστίου, i.e., from Sebaste, the name given to the number of synagogues here named. The probability is that there are three, corresponding to the geographical regions involved, (1) Rome and Italy, (2) N.E. Africa, (3) Asia Minor. In this case the Synagogue of the Libertines is the assembly of the "Freemen" from Rome, descendants of the Jews enslaved by Pompey after his conquest of Judaea 63 B.C. If, however, we take Λεβιτίου and Κυμαμωναὶ καὶ Αλεξάνδρον closely together, the first name must denote the people of some city or district. The obscure town Libertum (inferred from the title *Episcopus Libertinensis* in connexion with the synod of Carthage, *A.D.* 411) is less likely than the reading (Λῆβιόν) or *Λυφών* underlying certain Armenian versions and Syriac commentaries. The Greek towns lying west from Cyrene would naturally be called Libyan. In most places, however, these revised names, instead of being liberalized by their residence abroad, were more tenacious of Judaism and more bitter against Stephen than those who had never left Judaea.

**LIBERTY** (Lat. libertas, from liber, free), generally the state of freedom, especially opposed to subjection, imprisonment or slavery, or with such restricted or figurative meaning as the circumstances imply. The history of political liberty is in modern days identified practically with the progress of civiliza-

In a more particular sense, "a liberty" is the term for a franchise, a privilege or branch of the crown's prerogative granted to a subject, as, for example, that of executing legal process; hence the district over which the privilege extends. Such liberties are exempt from the jurisdiction of the sheriff and have separate commissions of the peace, but for purposes of local government form part of the county in which they are situated. The exemption from the jurisdiction of the sheriff was recognized in England by the Sheriffs Act 1887, which provides that the sheriff of a county shall appoint a deputy at the expense of the lord of the liberty, such deputy to reside in or near the liberty. The deputy receives and opens in the sheriff's name all writs, the return or execution of which belongs to the bailiff of the liberty, and issues to the bailiff the warrant required for the due execution of such writs. The bailiff then becomes liable for non-execution, mis-execution or insufficient return of any writs, and in the case of non-return of any writ, if the sheriff has delivered the writ to a bailiff of a liberty, the sheriff will be ordered to execute the writ notwithstanding the liberty, and must cause the bailiff to attend before the high court of justice and answer why he did not execute the writ.

In nautical phraseology various usages of the term are derived from its association with a sailor's leave on shore, e.g., liberty-man, liberty-day, liberty-ticket.

A *History of Modern Liberty,* in eight volumes, of which the third appeared in 1896, has been written by James Macmurray; see also *Lord Acton's Lectures,* and such works as J. S. Mill's *On Liberty* and Sir John Selden's *Introduction to Political Science.*

**LIBERTY PARTY,** the first political party organized in the United States to oppose the spread and restrict the political power of slavery, and the lineal precursor of the Free Soil and Republican parties. It originated in the Old North-west. Its organization was preceded there by a long anti-slavery religious movement. James G. Birney (q.v.), to whom more than to any other man belongs the honour of founding and leading the party, began to define the political duties of so-called "abolitionists" about 1836; but for several years thereafter he, in common with other leaders, continued to disclaim all idea of forming a political party. In state and local campaigns, however, non-partisan political action was attempted through the questioning of Whig and Democratic candidates. The utter futility of seeking to obtain in this way any satisfactory concessions to anti-slavery sentiment was speedily and abundantly proved. There arose, consequently, a division in the American Anti-Slavery Society between those who were led by W. L. Garrison (q.v.), and advocated political non-resistance—and, besides, had loaded down their anti-slavery views with a variety of religious and social vagaries, unpalatable to all but a small number—and those who were led by Birney, and advocated independent political action. The sentiment of the great majority of "abolitionists" was, in 1838, strongly for such action; and it was the party sanctioned and implied in the constitution and declared principles of the Anti-slavery Society; but the capture of that organization by the Garrisonians, in a "packed" convention in 1839, made it unavailable as a party nucleus—even if it had not already outgrown—and hastened a separate party organization. A convention of abolitionists at Warsaw, New York, in November 1839 had resolved that abolitionists were bound by every consideration of duty and expediency to organize an independent political party. Accordingly, the political abolitionists, in another convention at Albany, in April 1840, containing delegates from six states but not one from the North-west, launched the "Liberty Party," and nominated Birney for the presidency in the November election he received 7069 votes. 1

The political "abolitionists" were abolitionists only as they were restrictionists: they wished to use the federal government to exclude (or abolish) slavery from the federal Territories and the District of Columbia, but they saw no opportunity to attack slavery in the states—i.e. to attack the institution *per se;* also

1 Mr T. C. Smith estimates that probably not one in ten of even professcd abolitionists supported Birney; only in Massachusetts did he receive as much as 1% of the total vote cast.
they declared there should be "absolute and unqualified division of the General Government from slavery"—which implied an amendment of the constitution. They proposed to use ordinary moral and political means to attain their ends—not, like the Garrisonians, to abstain from voting, or favour the dissolution of the Union.

After 1840 the attempt began in earnest to organize the Liberty Party thoroughly, and unite all anti-slavery men. The North-west, where there was, after 1840, very little known of Garrison and his methods (T. C. Smith), was the most promising field, but though the contest of state and local campaigns gave morale to the party, it made scant political gains (in 1843 it cast hardly 10% of the total vote); it could not convince the people that slavery should be made the paramount question in politics. In 1844, however, the Texas question gave slavery precisely this pre-eminence in the presidential campaign. Until then, neither Whigs nor Democrats had regarded the Liberty Party seriously; now, however, each party charged that the Liberty movement was corruptly auxiliary to the other. As the campaign progressed, the Whigs alternately abused the Liberty men and made frantic appeals for their support. But the Liberty men were strongly opposed to Clay personally; and even if his equivocal campaign letters (see CLAY, HENRY) had not left exceedingly small ground for belief that he would resist the annexation of Texas, still the Liberty men were not such as to admit that an end justifies the means; therefore they again nominated Birney. He received 62,263 votes—many more than enough in New York to have carried that state and the presidency for Clay, had they been thrown to his support. The Whigs, therefore, blamed the Liberty Party for Democratic success and the annexation of Texas; but—quite apart from the issue of political ethics—it is almost certain that though Clay's chances were injured by the Liberty ticket, they were injured much more outside the Liberty ranks, by his own ebulitions. After 1844 the Liberty Party made little progress. Its leaders were never very strong as politicians, and its ablest organizer, Birney, was about this time compelled by an accident to abandon public life. Moreover, the election of 1844 was in a way fatal to the party; for it seemed to prove that though "abandon" was not the party programme, still its antecedents and personnel were too radical to unite the North; and above all it could not, after 1844, draw the disaffected Whigs, though their party was steadily moving toward anti-slavery their dislike of the Liberty Party effectively prevented union. Indeed, no party of one idea could hope to satisfy men who had been Whigs or Democrats. At the same time, anti-slavery Whigs and Democrats were segregating in state politics, and the issue of excluding slavery from the new territory acquired from Mexico afforded an opened opportunity to unite all anti-slavery men on the principle of the Wilmot Proviso (1846). The Liberty Party reached its greatest strength (casting 74,017 votes) in the state elections of 1846. Thereafter, though growing somewhat in New England, it rapidly became ineffective in the rest of the North. Many, including Birney, thought it should cease to be an isolated party of one idea—striving for mere balance of power between Whigs and Democrats, welcoming small concessions from them, almost dependent upon them. Some wished to revivify it by making it a party of general reform. One result was the secession and formation of the Liberty League, which in 1847 nominated Gerrit Smith for the presidency. No adequate effort was made to take advantage of the disintegration of other parties. In October 1847, at Buffalo, was held the third and last national convention. John P. Hale—whose election to the United States Senate had justified the first successful union of

Liberty men with other anti-slavery men in state politics—was nominated for the presidency. But the nomination by the Democrats of Lewis Cass shored up the Democratic organization in New York and the North-west; and when the Whigs nominated General Taylor, adopted a non-committal platform, and showed hostility to the Wilmot Proviso, the way was clear for a union of all anti-slavery men. The Liberty Party, abandoning therefore its independent nominations, joined in the first convention and nominations of the Free Soil Party (q.v.), thereby practically losing its identity, although it continued until after the organization of the Republican Party to maintain something of a semi-independent organization. The Liberty Party has the unique honour among third-parties in the United States of seeing its principles rapidly adopted and realized.

See T. C. Smith, History of the Liberty and Free Soil Parties in the North-west (Harvard University Historical Studies, New York, 1897), and lives and writings of all the public men mentioned above; also of G. W. Julian, J. R. Giddings and S. P. Chase.

LIBITINA, an old Roman goddess of funerals. She had a sanctuary in a sacred grove (perhaps on the Esquiline), where, by an ordinance of Servius Tullius, a piece of money (locus Libitinæ) was deposited whenever a death took place. Here the undertakers (libitinarii), who carried out all funeral arrangements by contract, had their offices, and everything necessary was kept for sale or hire; here all deaths were registered for statistical purposes. The word Libitina then came to be used for the business of an undertaker, funeral requisites, and (in the poet's) for death itself. By later antiquarians Libitina was sometimes identified with Persephone, but more commonly partly or completely with Venus Lubentia or Lubentina, an Italian goddess of gardens. The similarity of name and the fact that Venus Lubentia had a sanctuary in the grove of Libitina favoured this idea. Further, Plutarch (Quaest. Rom. 23) mentions a small statue at Delphi of Aphrodite Epiphania (A. of tombs = Venus Libitina), to which the spirits of the dead were summoned. The inconsistency of selling funeral requisites in the temple of Libitina, seeing that she is identified with Venus, is explained by him as indicating that one and the same goddess presides over birth and death; or the association of such things with the goddess of love and pleasure is intended to show that death is not a calamity, but rather a consummation to be desired. Libitina may, however, have been originally an earth goddess, connected with luxuriant nature and the enjoyments of life (cf. lubet, libida); then, all such deities being connected with the underworld, she also became the goddess of death, and that side of her character predominated in the later conceptions.

See Plutarck, Numa, 12; Dion. Halic. iv, 15; Festus, 16, s.v. (*Lubentina*); Juvenal, xii. 121, with Mayow's note; G. W. Sowa in Roscher's Lexicon der Mythologie, s.v.

LIBMANAN, a town of the province of Ambos Camarines, Luzon, Philippine Islands, on the Libmanan river, 14 m. N.W. of Nueva Cáceres, the capital. Pop. (1903) 17,416. It is about 49 m. N.E. of the Bay of San Miguel. Rice, coco-nuts, hemp, Indian corn, sugarcane, bejoco, arica nuts and camotees, are grown in the vicinity, and the manufactures include hemp goods, alcohol (from coco-nut-palm sap), copra, and baskets, chairs, hammocks and hats of bejoco and bamboo. The Libmanan river, a tributary of the Bicol, into which it empties 2 m. below the town, is famous for its clear cold water and for its sulphur springs. The language is Bicol.

LIBO, in ancient Rome; the name of a family belonging to the Scribonian gens. It is chiefly interesting for its connexion with the Puteal Scribonianum or Puteal Libinum in the forum of Rome, 3 dedicated or restored by one of its members, perhaps the praetor of 304 B.C., or the tribune of the people in 140 B.C. In its vicinity the praetor's tribunal, removed from the comitia in the 2nd century B.C., held its sittings, which led to the place becoming the haunt of litigants, money-lenders and business people. According to ancient authorities, the Puteal Libonis

1 Birney's vote was reduced by a disgraceful election trick by the Whigs (the circulation of a forced letter on the eve of the election); a trick to which he had exposed himself by an ingenuously hostile reception of Democratic advances in a matter of local good-government in Michigan.

2 E.g. Horace Greely made the Whig charge; but in later life he repeatedly attributed Clay's defeat simply to Clay's own letters; and Horace Greeley's important opinion see footnote to Know Nothing Party.
was between the temples of Castor and Vesta, near the Porticus Julia and the Arcus Fabrium, but no remains have been
discovered. The idea that an irregular circle of travertine blocks,
found near the temple of Castor, formed part of the puteal is
now abandoned.

See Horace, Sat. ii. 6. 35, Eff. i. 19. 8; Cicero, Pro Sesto. 8; for
the well-known coin of L. Scribonius Libo, representing the puteal of
Libo, which rather resembles a cippus (sepolchral monument) or an
altar, with laurel wreaths, two lilies and a pair of scales;
not the jaws of a horse,
both the staffs of the seneschal and a pair of scales,
with the whole held by a woman, (perhaps symbolical of Vulcanus as forger
of lightning), see C. Hülse, "The Roman Forum" (Eng. trans. by
J. B. Carter, 1906), p. 150, where a marble imitation found at Voli
is also given.

LIBON, a Greek architect, born at Elis, who was employed to
build the great temple of Zeus at Olympia (q.v.) about 460 B.C.
(Pausanias v. 10. 2).

LIBOURNE, a town of south-western France, capital of an
arrondissement of the department of Gironde, situated at the
confluence of the Isle with the Dordogne, 22 m. E.N. of
Bordeaux on the railway to Angoulême. Pop. (1906) town, 15,280;
commune, 19,323. The sea is 50 m. distant, but the tide affects
the river so as to admit of vessels drawing 14 ft. reaching the
town at the highest tides. The Dordogne is here crossed by a
stone bridge 402 ft. long, and a suspension bridge across the Isle
connects Libourne with Fronsac, built on a hill on which in
feudal times stood a powerful fortress. Libourne is regularly
built. The Gothic church, restored in the 19th century, has a
stone spire 232 ft. high. On the quay there is a machicolated
clock-tower which is a survival of the ramparts of the 14th
century; 2 of the surrounding towers and a small museum and
a library, is a quaint relic of the 16th century. There is a
statue of the Duc Decazes, who was born in the neighbourhood.
The sub-prefecture, tribunals of first instance and of
commerce, and a communal college are among the public institutions.
The principal articles of commerce are the wines and
brandies of the district. Printing and cooperation are among the industries.

Like other assemblages at the confluence of important rivers, that of
Libourne was appropriated at an early period. Under the
Romans Condut stood rather more than a mile to the south of
the present Libourne; it was destroyed during the troubles of
the 3rd century. Resuscitated by Charlemagne, it was
rebuilt in 1260, under its present name and on the site and plan it
still retains, by Roger de Leybourne (of Leybourne in Kent),
seneschal of Guîenne acting under the authority of King
Edward I. of England. It suffered considerably in the struggles
of the French and English for the possession of Guîenne in the
14th century.

See R. Guinod, Hist. de Libourne (2nd ed., 2 vols., Libourne,
1876-1877).

LIBRA ("The Balance"), in astronomy, the 7th sign of the
zodiac (q.v.), denoted by the symbol ≈, resembling a pair of
scales, probably in allusion to the fact that when the sun enters
this part of the ecliptic, at the autumnal equinox, the days and
nights are equal. It is also a constellation, not mentioned by
Eudoxus or Aratus, but by Manetho (3rd century B.C.) and
Geminus (1st century B.C.), and included by Ptolemy in his
48 asterisms; Ptolemy catalogued 17 stars, Tycho Brahe 10, and
Hevelius 20. δ Librae is an Algol (q.v.) variable, the range
of magnitude being 5.0 to 6.2, and the period 2 days 1 hr. 51 min.;
and the cluster M. 5 Librae is a faint globular cluster of which
only about one star in eleven is variable.

LIBRARIES. A library (from Lat. liber, book), in the modern
sense, is a collection of printed or written literature. As such, it
implies an advanced and elaborate civilization. If the term be
extended to any considerable collection of written documents,
it must be nearly as old as civilization itself. The earliest
use to which the invention of inscribed or written signs was put
was probably to record important religious and political trans-
actions. These records would naturally be preserved in sacred
places, and accordingly the earliest libraries of the world were
probably temples, and the earliest librarians priests. And
indeed before the extension of the arts of writing and reading the
priests were the only persons who could perform such work as,
e.g. the compilation of the Annales Maximi, which was the duty of
the pontifices in ancient Rome. The beginnings of literature
proper in the shape of ballads and songs may have continued to
be conveyed orally only from one generation to another, long after
the record of important religious or civil events was regularly
committed to writing. The earliest collections of which we
know anything, therefore, were collections of archives. Of this
character appear to have been such famous collections as that
of the Medians at Ecbatana, the Persians at Susa or the hiero-
glyphic archives of Knossos discovered by A. J. Evans (Scripta
Minoa, 1909) of a date synchronizing with the XIIth Egyptian
dynasty. It is not until the development of arts and sciences,
and the growth of a considerable written literature, and even of
a distinct literary class, that we find collections of books which
may be called libraries in our modern sense. It is of libraries
in the modern sense, and not, except incidentally, of archives
that we are to speak.

ANCIENT LIBRARIES

The researches which have followed the discoveries of P. E.
Botta and Sir H. Layard have thrown unexpected light
not only upon the history but upon the arts, the
sciences and the literatures of the ancient civilizations
of Babylonia and Assyria. In all these wondrous revelations no
facts are more interesting than those which show the existence
of extensive libraries so many ages ago, and none are more
eloquent of the elaborateness of these forgotten civilizations.
In the course of his excavations at Nineveh in 1850, Layard
came upon some chambers in the south-west palace, the floor of
which, as well as the adjoining rooms, was covered to the depth
of a foot with tablets of clay, covered with cuneiform characters,
in many cases so small as to require a magnifying glass. These
varied in size from 1 to 12 in. square. A great number of them
were broken, as Layard supposed by the falling in of the roof,
but as George Smith thought by having fallen from the upper
storey, upon which he believed the collection to have been placed.
These tablets formed the library of the great monarch Assur-
ban-pal—the Sardanapalus of the Greeks—the greatest patron
of literature amongst the Assyrians. It is estimated that this
library consisted of some ten thousand distinct works and
documents, some of the works extending over several tablets.
The tablets appear to have been methodically arranged and cata-
alogued, and the library seems to have been thrown open for the
general use of the king’s subjects. A great portion of this
library has already been brought to England and deposited in
the British museum, but it is calculated that there still remain
some 20,000 fragments to be gathered up. For further details to
Assyrian libraries, and the still earlier Babylonian libraries
at Tello, the ancient Lagash, and at Niffer, the ancient Nippur,
from which the Assyrians drew their science and literature, see
BABYLONIA and NIPPUR.

Of the libraries of ancient Egypt our knowledge is scattered
and imperfect, but at a time extending to more than 6000
years ago we find numerous scribes of many classes who re-
corded official events in the life of their royal masters
or details of their domestic affairs and business trans-
actions. Besides this official literature we possess
evidence of many commentaries on the sacred texts, as well
as historical treatises, works on moral philosophy and proverbial
wisdom, science, collections of medical receipts as well as a
very great variety of popular novels and humoristic pieces. At an early
date Heliopolis was a literary centre of great importance with
culture akin to the Babylonian. Attached to every temple
were professional scribes whose function was partly religious
and partly scientific. The sacred books of Thoth constituted as
it was a complete encyclopaedia of religion and science, and on
these books was gradually accumulated an immense mass of
exposition and commentary. We possess a record relating to
"the land of the collected works [library] of Khufu," a monarch
of the IVth dynasty, and a similar inscription relating to the
library of Khafra, the builder of the second pyramid. At Edfu

1 See Menant, Bibliothèque du palais de Ninive (Paris, 1880).
the library was a small chamber in the temple, on the wall of which is a list of books, among them a manual of Egyptian geography (Brugsch, History of Egypt, 1881, i. 240). The exact position of Akhenaten's library (or archives) of clay tablets is known and the name of the room has been read on the books of which it has been built. A library of charred books has been found at Mendes (Egypt Exp. Fund, Two Hieroglyphic Papyri), and we have references to temple libraries in the Silsileh "Nile" stelae and perhaps in the great Harris papyri. The most famous of the Egyptian libraries is that of King Osymandias, described by Diodorus Siculus, who relates that it bore an inscription which he renders by the Greek words ΠΤΧΗΣΙΤΡΕΠΕΙΝ "the Dispensary of the Soul." Osymandias has been identified with the great king Rameses II. (1300-1236 B.C.) and the seat of the library is supposed to have been the Ramessaeum at Western Thebes. Amen-em-hant was the name of one of the directors of the Theban libraries. Papyri from the palace of a later date, have been discovered by Professor W. F. H. LYons Petrie. At Thebes the scribes of the "Foreign Office" are depicted at work in a room which was perhaps rather an office than a library. The famous Tel-el-Amarna tablets (1383-1365 B.C.) were stored in "the place of the records of the King." There were record offices attached to the granary and treasury departments and we know of a school or college for the reproduction of books, which were kept in boxes and in jars. According to Eusebius there was a great collection at Memphis. A heavy blow was dealt to the old Egyptian literature by the Persian invasion, and many books were carried away by the conquerors. The Egyptians were only delivered from the yoke of Persia to succumb to that of Greece and Rome and henceforward their civilization was dominated by foreign influences. Of the Greek libraries under the Ptolemies we shall speak a little further on.

Of the libraries of ancient Greece we have very little knowledge, and such knowledge as we possess comes to us for the most part from later compilers. Amongst those who are known to have collected books are Pisistratus, Polycrates of Samos, Euclid the Athenian, Nicocrates of Cyzicus, Euripides and Aristotle (Athenaeus i. 4). At Cnidus there is said to have been a special collection of works upon medicine. Pisistratus is reported to have been the first of the Greeks who collected books on a large scale. Aulus Gellius, indeed, tells us, in language perhaps "not well suited to the 6th century B.C.," that he was the first to establish a public library. The authority of Aulus Gellius is hardly sufficient to secure credit for the story that this library was carried away into Persia by Xerxes and subsequently restored to the Athenians by Seleucus Niger. Plato is known to have been a collector; and Xenophon tells us of the library of Euthydemus. The library of Aristotle was bequeathed by him to his disciple Theophrastus, and by Theophrastus to Neleus, who carried it to Scepsis, where it is said to have been discovered by Professor W. F. H. LYons Petrie. Neleus seems to have been a student of the kings of Pergamum. Its subsequent fate has given rise to much controversy, but, according to Strabo (xiii. pp. 608, 500), it was sold to Apellion of Teos, who carried it to Athens, where after Apellion's death it fell a prey to the conqueror Sulla, and was transported by him to Rome. The story told by Athenaeus (i. 4) is that the library of Neleus was purchased by Ptolemy Philadelphus. The names of a few other libraries in Greece are barely known to us from inscriptions; of their character and contents we know nothing. If, indeed, we are to trust Strabo entirely, we must believe that Aristotle was the first person who collected a library, and that he communicated the taste for collecting to the sovereigns of Egypt. It is at all events certain that the libraries of Alexandria were the most important as they were the most celebrated of the ancient world. Under the enlightened rule of the Ptolemies a society of librarians was formed to attract to their capital. It seems pretty certain that Ptolemy Soter had already begun to collect books, but it was in the reign of Ptolemy Philadelphus that the libraries were properly organized and established in separate buildings. Ptolemy Philadelphus sent into every part of Greece and Asia to secure the most valuable works, and no exertions or expense were spared in enriching the collections. Ptolemy Euergetes, his successor, is said to have caused all books brought into Egypt by foreigners to be seized for the benefit of the library, while the owners had to be content with receiving copies of them in exchange. Nor did the Alexandrian scholars exhibit the usual Hellenic exclusiveness, and many of the treasures of Egyptian and even of Hebrew literature were by their means translated into Greek. There were two libraries at Alexandria; the larger, in the Bruchium quarter, was in connexion with the Museum, a sort of academy, while the smaller was placed in the Serapeum. The number of volumes in these libraries was very large, although it is difficult to attain any certainty as to the real numbers amongst the widely varying accounts. According to a scholium of Tzetzes, who appears to have drawn his information from the authority of Callimachus and Eratothenees, who had been librarians at Alexandria, there were 42,800 ordered rolls in the Serapeum alone, and 40,000 in the Bruchium. This enumeration seems to refer to the librarianship of Callimachus himself under Ptolemy Euergetes. In any case the figures agree tolerably well with those given by Aulus Gellius (700,000) and Seneca (400,000). It should be observed that, as the ancient roll or volume usually contained a much smaller quantity of matter than a modern book—so that, e.g. the history of Herodotus might form nine "books" or volumes, and the Iliad of Homer twenty-four—these numbers must be discounted for the purposes of comparison with modern collections. The series of the five first librarians at Alexandria appears to be pretty well established as follows: Zenodotus, Callimachus, Eratothenees, Apollonius and Aristophanes; and their activity covers a period of about a century. The first experiments in bibliography appear to have been made in producing catalogues of the Alexandrian libraries. Amongst other lists, two catalogues were prepared by order of Ptolemy Philadelphus, one of the ancient and the other of the modern books, brought to Alexandria by the conquests of the Ptolemies. Of the works of Callimachus, which form a catalogue of all the principal works arranged in 120 classes. When Caesar set fire to the fleet in the harbour of Alexandria, the flames accidentally extended to the larger library of the Bruchium, and it was destroyed. Antony endeavoured to repair the loss by presenting to Cleopatra the library from Pergamum. This was very probably placed in the Bruchium, as this continued to be the literary quarter of Alexandria until the time of Aurelian. Thenceforward the Serapeum became the principal library. The usual statement that from the date of the restoration of the Bruchium under Cleopatra the libraries continued in a flourishing condition until they were destroyed after the conquest of Alexandria by the Saracens in A.D. 640 can hardly be supported. It is very possible that one of the libraries perished when the Bruchium quarter was destroyed by Aurelian, A.D. 275. In 386 or 391 an edict of Theodosius, the other of the emperors, placed in the collection of the churches, the works of all religions were mingled with the sacred volumes, and the books were pillaged by the Christians. When we take into account the disordered condition of the times, and the neglect into which literature and science had fallen, there can be little difficulty in believing that there were but few books left to be destroyed by the soldiers of Amru. The familiar anecdote of the caliph's message to his general rests mainly upon the evidence of Abulfaraj, so that we may be tempted to agree with Gibbon that the report of a stranger who wrote at the end of six hundred years is overbalanced by the silence of earlier and native annalists. It is, however, so far from easy to settle the question that a cloud of names could easily be cited upon either side, while some of the most careful inquirers confess the difficulty of a decision (see ALEXANDRIA, III.).

The magnificence and renown of the libraries of the Ptolemies excited the rivalry of the kings of Pergamum, who vied with the Egyptian rulers in their encouragement of literature. The Pergamene, Die alexandrinischen Bibliotheken, p. 22; Opus. phil. i. § 123.

5 Parthey (Alexandrinisches Museum) assigns topographical reasons for doubting this story.
6 Some of the authorities have been collected by Parthey, op. cit.,
German researches in the acropolis of Pergamum between 1878 and 1896 revealed four rooms which had originally been appropriated to the library (Alex. Conze, *Die pergumen. Bibliothek*, 1884). Despite the obstacles presented by the embargo placed by the Ptolemies upon the export of papyri, the library of the Attali attained considerable importance, and, as we have seen, when it was transported to Egypt numbered 200,000 vols. We learn from a notice in Suidas that in 221 B.C. Antiochus the Great summoned the poet and grammarian Euphorion of Chalcis to be his librarian.

The early Romans were far too warlike and practical a people to devote much attention to literature, and it is not until the last century of the republic that we hear of libraries in Rome. The collections of Carthage, which fell into their hands when Scipio sacked that city (146 B.C.), had no attractions for them; and with the exception of the writings of Mago upon agriculture, which the senate reserved for translation into Latin, they bestowed all the books upon the kingslets of Africa (Pliny, *H. N.*, xviii. 5). It is in accordance with the military character of the Romans that the first considerable collections of which we hear in Rome were brought there as the spoils of war. The first of these was that brought by Aemilius Paulus from Macedonia after the conquest of Perseus (167 B.C.). The library of the conquered monarch was all that he reserved from the prizes of victory for himself and his sons, who were fond of letters. Next came the library of Apollon the Teian, brought from Athens by Sulla (86 B.C.). This passed at his death into the hands of his son, but of its later history nothing is known. The rich stores of literature brought home by Lucullus from his eastern conquests (about 67 B.C.) were freely thrown open to his friends and to men of letters. Accordingly his library and the neighbouring walks were much resorted to, especially by Greeks. It was now becoming fashionable for rich men to furnish their libraries well, and the fashion prevailed until it became the subject of Seneca's scorn and Lucian's wit. The zeal of Cicero and Atticus in adding to their collections is well known to every reader of the classics. Tyrannion is said to have had 30,000 vols. of his own; and that M. Terentius Varro had large collections we may infer from Cicero's writing to him: "Si hortum in bibliotheca habes, nihil deerit." Not to prolong the list of private collectors, Sertorius Sammonicus is said to have left to his pupil the young Gordian no less than 62,000 vols. Amongst the numerous projects entertained by Caesar was that of presenting Rome with public libraries, though it is doubtful whether any steps were actually taken towards its execution. The task of collecting and arranging the books was entrusted to Varro. This commission, as well as his own fondness for books, may have led him to write the book upon libraries of which a few words only have come down to us, preserved by a grammarian. The honour of being the first actually to dedicate a library to the public is said by Pliny and Ovid to have fallen to G. Asinius Pollio, who erected a library in the Atrium Libertatis on Mount Aventine, defraying the cost from the spoils of his Illyrian campaign. The library of Pollio was followed by the public libraries established by Augustus. That emperor, who did so much for the embellishment of the city, erected two libraries, the Octavian and the Palatine. The former was founded (33 B.C.) in honour of his sister, and was placed in the Porticus Octaviae, a magnificent structure, the lower part of which served as a promenade, while the upper part contained the library. The charge of the books was committed to C. Mellinus. The other library formed by Augustus was attached to the temple of Apollo on the Palatine hill, and appears from inscriptions to have contained 400,000 vols. The library had a very high reputation, and, indeed, it is probable that Professor Pernier is correct in supposing that the fire which raged at Rome for three days in the reign of Titus. The Palatine was, at all events in great part, destroyed by fire in the reign of Commodus. The story that its collections were destroyed by order of Pope Gregory the Great in the 6th century is now generally rejected. The successors of Augustus, though they did not equal him in their patronage of learning, maintained the tradition of forming libraries. Tiberius, his immediate successor, established one in his splendid house on the Palatine, to which Gallus refers as the "Tibonian library," and Suetonius relates that he caused the writings and images of his favourite Greek poets to be placed in the public libraries. Vespasian established a library in the Temple of Peace erected after the burning of the city under Nero. Domitian restored the libraries which had been destroyed in the same conflagration, procuring books from every quarter, and even sending to Alexandria to have copies made. He is also said to have founded the Capitoline library, though others give the credit to Hadrian. The most famous and important of the imperial libraries, however, was that created by Ulpius Trajanus, known as the Ulpian library, which was first established in the Forum of Trajan, but was afterwards removed to the baths of Dioecletian. In this library were deposited by Trajan the "libri linteli" and "libri elepontini," upon which the senators consulted and other transactions relating to the emperors were written. The library of Domitian, which had been destroyed by fire in the reign of Commodus, was restored by Gordian, who added to it the books bequeathed to him by Sertorius Sammonicus. Altogether in the 4th century there are said to have been twenty-eight public libraries in Rome.

Nor were public libraries confined to Rome. We possess records of at least 24 places in Italy, the Grecian provinces, Asia Minor, Cyprus and Africa in which libraries had been established, most of them attached to temples, usually through the liberality of generous individuals. The library which the younger Pliny dedicated to his townsmen at Comum cost a million sesterces and he contributed a large sum to the support of a library at Milan. Hadrian established one at Athens, described by Pausianias, and recently identified with a building called the Stoa of Hadrian, which shows a striking similarity with the precinct of Athena at Pergamum. Strabo mentions a library at Smyrna; Aulus Gellius one at Patrae and another at Tibur from which books could be borrowed. Recent discoveries at Ephesus in Asia Minor and Timagad in Algeria have furnished precise information as to the structural plan of these buildings. The library at Ephesus was founded by T. Julius Aquila Polemaenaeus in memory of his father, pro-consul of Asia in the time of Trajan, about A.D. 106-107. The library at Timagad was established at a cost of 400,000 sesterces by M. Julius Quintianus Flavius Rogatianus, who probably lived in the 3rd century (R. Cagnat, *Les Bibliothèques municipales dans l'Empire Romain*, 1906, Mem. de l'Acad. des Ins., tom. xiv, pp. 37-62). At Ephesus the light came through a circular opening in the roof; the library at Timagad greatly resembles that discovered at Pompeii and possesses a system of book stores. All these buildings followed the same general plan, consisting of a reading-room and more or less ample book stores; the former was either rectangular or semi-circular in shape and was approached under a stately portico and colonnade. In a niche facing the entrance a statue was always erected; that formerly at Pergamum—a figure of Minerva—is now preserved at Berlin. From a well-known line of Juvenal (Sat. iii. 219) we may assume that a statue of the goddess was usually placed in libraries. The reading-room was also ornamented with busts or life-sized images of celebrated writers. The portraits or authors were also painted on medallions on the presses (armaria) in which the books or rolls were preserved as at Ephesus, and Greek and Latin medallions decorated the walls, as in a private library discovered by Lanciani in 1883 at Rome (*Ancient Rome*, 1888, p. 193). Moveable seats, known to us by pictorial representations, were in use. The books were classified, and the presses (framed of precious woods and highly ornamented) were numbered to facilitate reference from the catalogues. A private library discovered at Herculanum contained 1756 MSS. placed on shelves round the room to a height of about 6 ft. with a central press. In the public rooms some of the books were arranged
in the reading-room and some in the adjacent book stores. The Christian libraries of later foundation closely followed the classical prototypes not only in their structure but also in smaller details. The general appearance of a Roman library is preserved in the library of the Vatican fitted up by Sextus V. in 1587 with painted preses, busts and antique vases.

As the number of libraries in Rome increased, the librarian, who was generally a slave or freedman, became a recognized public functionary. The names of several librarians are preserved to us in inscriptions, including that of C. Hymenaeus, who appears to have fulfilled the double function of physician and librarian to Augustus. The general superintendence of the public libraries was committed to a special official. Thus from Nero to Trajan, Dionysius, an Alexandrian rhetorician, discharged this function. Under Hadrian it was entrusted to his former tutor C. Julius Veitinius, who afterwards became administrator of the Museum at Alexandria.

When the seat of empire was removed by Constantine to his new capital upon the Bosphorus, the emperor established a collection there, in which Christian literature was probably admitted for the first time into an imperial library. Diligent search was made after the Christian books which had been doomed to destruction by Diocletian. Even at the death of Constantine, however, the number of books which had been brought together amounted only to 6000. The smallness of the number, it has been suggested, seems to show that the Constantine library was mainly intended as a repository of Christian literature. However this may be, the collection was greatly enlarged by some of Constantine’s successors, especially by Julian and Theodosius, at whose death it is said to have increased to 100,000 vols. Julian, himself a close student and voluminous writer, though he did his best to discourage learning among the Christians, and to destroy their libraries, not only augmented the library at Constantineople, but founded others, including one at Nisibis, which was soon afterwards destroyed by fire. From the Theodosian code we learn that in the time of that emperor a staff of seven抄ists was attached to the library at Constantineople under the direction of the librarian. The library was burnt under the emperor Zen in 477, but was again restored.

Meanwhile, as Christianity made its way and a distinctively Christian literature grew up, the institution of libraries became part of the ecclesiastical organization. Bishop Alexander (d. a.d. 250) established a church library at Jerusalem, and it became the rule to attach to every church a collection necessary for the instruction of Christian doctrine. The first library in this sense appears to have been founded at Cirta, at Constantineople and at Rome. The basilica of St Lawrence at Rome contained a library or archivium founded by Pope Damasus at the end of the 4th century. Most of these collections were housed in the sacred edifices and consisted largely of copies of the Holy Scriptures, liturgical volumes and works of devotion. They also included the Gesta Martyrum and Matriculae Pauperorum and official correspondence. Many of the basilicas had the apse subdivided into three smaller hemicycles, one of which contained the library (Lanciani, op. cit. p. 187). The largest of these libraries, that founded by Pamphilus (d. a.d. 309) at Caesarea, and said to have been increased by Eusebius, the historian of the church, to 30,000 vols., is frequently mentioned by St Jerome. St Augustine bequeathed his collection to the library of the church at Hippo, which was fortunate enough to escape destruction at the hands of the Vandals. The hermit communities of the Egyptian deserts formed organizations which developed into the later monastic orders of Western Europe and the accumulation of books for the brethren was one of their cares.

The removal of the capital to Byzantium was in its result a serious blow to literature. Henceforward the science and learning of the East and West were divorced. The libraries of Rome ceased to collect the writings of the Greeks, while the Greek libraries had never cared much to collect Latin literature. The influence of the church became increasingly hostile to the study of pagan letters. The repeated irruptions of the barbarians soon swept the old learning and libraries alike from the soil of Italy. With the close of the Western empire in 476 the ancient history of libraries may be said to cease.

**MEDIEVAL PERIOD**

During the first few centuries after the fall of the Western empire, literary activity at Constantinople had fallen to its lowest ebb. In the West, amidst the general neglect of learning and literature, the collecting of books, though not wholly forgotten, was cared for by few. Sidonius Apollinaris tells us of the libraries of several private collectors in Gaul. Publilus Consentius possessed a library at his villa near Narbonne which was due to the labour of three generations. The most notable of these appears to have been the prefect Tonantius Ferreolus, who had formed in his villa of Prusiana, near Nimes, a collection which his friend playfully compares to that of Alexandria. The Goths, who had been introduced to the Scriptures in their own language by Ulfilas in the 4th century, began to pay some attention to Latin literature. Cassiodorus, the favourite minister of Theodoric, was a collector as well as an author, and on giving up the cares of government retired to a monastery which he founded in Calabria, where he employed his monks in the transcription of books.

Henceforward the charge of books as well as of education fell more and more exclusively into the hands of the church. While the old schools of the rhetoricians died out new monasteries arose everywhere. Knowledge was no longer pursued for its own sake, but became subsidiary to religious and theological teaching. The proscription of the old classical literature, which is symbolized in the fable of the destruction of the Palatine library by Gregory the Great, was only too effectual. The Gregorian tradition of opposition to pagan learning long continued to dominate the literary pursuits of the monastic orders and the labours of the scriptorium.

During the 6th and 7th centuries the learning which had been driven from the Continent took refuge in the British Islands, where it was removed from the political disturbances of the mainland. In the Irish monasteries during this period there appear to have been many books, and the Venerable Bede was superior to any scholar of his age. Theodore of Tarsus brought a considerable number of books to Canterbury from Rome in the 7th century, including several Greek authors. The library of York, which was founded by Archbishop Egbert, was almost more famous than that of Canterbury. The verses are well known in which Alcuin describes the extensive library of the latter church, and the large list of authors whom he enumerates is superior to that of any other library possessed by either England or France in the 12th century, when it was unhappily burnt. The inroads of the Normans in the 9th and 10th centuries had been fatal to the monastic libraries on both sides of the channel. It was from York that Alcuin came to Charlemagne to superintend the school attached to his palace; and it was doubtless inspired by Alcuin that Charles issued the memorable document which enjoined that in the bishoprics and monasteries within his realm care should be taken that there shall be not only a regular manner of life, but also the study of letters. When Alcuin finally retired from the court to the abbacy of Tours, there to carry out his own theory of monastic discipline and instruction, he wrote to Charles for leave to send to York for copies of the books of which they had so much need at Tours. While Alcuin thus increased the library at Tours, Charlemagne enlarged that at Fulda, which had been founded in 774, and which all through the middle ages stood in great respect. Lupus Servatus, a pupil of Hrabanus Maurus at Fulda, and afterwards abbot of Ferrières, was a devoted student of the classics and a great collector of books. His correspondence illustrates the difficulties which then attended the study of literature through the paucity and dearth of books, the declining care for learning, and the increasing troubles of the time. Nor were private collections of books altogether wanting during the period in which Charlemagne and his successors laboured to restore the lost traditions of
liberal education and literature. Pepin le Bref had indeed met with scanty response to the request for books which he addressed to the pontiff Paul I. Charlemagne, however, collected a considerable number of choice books for his private use in two places. Although these collections were dispersed at his death, his son Louis formed a library which continued to exist under Charles the Bald. About the same time Everard, count of Friuli, formed a considerable collection which he bequeathed to a monastery. But the greatest private collector of the Middle Ages was doubtless Gerbert, Pope Sylvester II., who showed the utmost zeal and spent large sums in collecting books, not only in Rome and Italy, but from Germany, Belgium and even from Spain. The hopes of a revival of secular literature fell with the decline of the schools established by Charles and his successors. The knowledge of letters remained the prerogative of the church, and for the next four or five centuries the collecting and multiplication of books were almost entirely confined to the monasteries. Several of the greater orders made these an express duty; this was especially the case with the Benedictines. It was the first care of St Benedict, we are told, that in each newly founded monastery there should be a library, "et velut curia quasdam illustrium auctorum." Monte Cassino became the starting-point of a long line of institutions which were destined to be the centres of religion and of literature. It must indeed be remembered that literature in the sense of St Benedict meant Biblical and theological works, the lives of the saints and martyrs, and the lives and writings of the fathers. Of the reformed Benedictine orders the Carthusians and the Cistercians were those most devoted to literary pursuits. The abbeys of Fleury, of Melk and of St Gall were remarkable for the splendour of their libraries. In a later age the labours of the congregation of St Maur form one of the most striking chapters in the history of learning. The Augustinians and the Dominicans rank next to the Benedictines in their care for literature. The libraries of St Geneviève and St Victor, belonging to the former, were amongst the largest of the monastic collections. Although their poverty might seem to put them at a disadvantage as collectors, the mendicant orders cultivated literature with much assiduity, and were closely connected with the intellectual movement to which the universities owed their rise. In England Richard of Bury praises them for their extraordinary diligence in collecting books. Sir Richard Whittington built a large library for the Grey Friars in London, and they possessed considerable libraries at Oxford.

It would be impossible to attempt here an account of all the libraries established by the monastic orders. We must be content to enumerate a few of the most eminent.

In Italy Monte Cassino is a striking example of the dangers and vicissitudes to which monastic collections were exposed. Ruined by the Lombards in the 6th century, the monastery was rebuilt and a library established, to fall a prey to Saracens and to fire in the 9th. The collection then re-formed survived many other chances and changes, and still exists. Boccaccio gives a melancholy description of its condition in his day. It affords a conspicuous example of monastic industry in the transcription not only of theological but also of classical works. The library of Bobbio, which owed its existence to Irish monks, was famous for its palimpsests. The collection, of which a catalogue of the 10th century is given by Muratori (Antiq. Ital. Med. Art. iii. 817-824), was mainly transferred to the Ambrosian library at Milan. Of the library of Pomposa, near Ravenna, Montfauncon has printed a catalogue dating from the 11th century (Diarium Italicum, chart. xxi.).

Of the monastic libraries of France the principal were those of Fleury, of Cluny, of St Riquier and of Corbie. At Fleury Abbot Macharius in 1146 imposed a contribution for library purposes upon the officers of the community and its dependencies, an example which was followed elsewhere. After many vicissitudes, its MSS., numbering 238, were deposited in 1793 in the town library of Orléans. The library of St Riquier in the time of Louis the Pious contained 256 MSS., with over 500 works. Of the collection at Corbie in Picardy we have also catalogues dating from the 12th and from the 17th centuries. Corbie was famous for the industry of its transcribers, and appears to have stood in active literary intercourse with other monasteries. In 1683-1687, four of its choicest manuscripts were removed to St Germain-des-Prés. The remainder were removed after 1794, partly to the national library at Paris, partly to the town library of Amiens.

The chief monastic libraries of Germany were at Fulda, Corvey, Reichenau and Sponheim. The library at Fulda owed much to Charlemagne and to its abbot Hrabanus Maurus. Under Abbot Sturmius four hundred monks were hired as copists. In 1581 the collection numbered 774 volumes. The library of Corvey on the Weser, after being despoiled of some of its treasures in the Reformation age, was presented to the university of Marburg in 1718. It then contained 2000 volumes, of which 500 are extant. The library of Reichenau, of which several catalogues are extant, fell a prey to fire and neglect, and its ruin was consummated by the Thirty Years' War. The library of Sponheim owes its great renown to John Trithemius, who was abbot at the close of the 15th century. He found it reduced to 10 vols., and left it with upwards of 2000 at his retirement. The library at St Gall, formed as early as 816 by Gozbert, its second abbott, still exists.

In England the principal collections were those of Canterbury, York, Wearmouth, Jarrow, Whitby, Glastonbury, Croyland, Peterborough and Durham. Of the library of Glastonbury, the monastery of ChristChurch, Canterbury, originally founded by Augustine and Theodore, and restored by Lanfranc and Anselm, a catalogue has been preserved dating from the 13th or 14th century, and containing 698 volumes, with about 3000 works. Bennet Bispoc, the first abbot of Wearmouth, made five journeys to Rome, and on each occasion returned with a store of books for the library. It was destroyed by the Danes about 867. Of the library at Whitby there is a catalogue dating from the 12th century. The catalogue of Glastonbury has been printed by Hearne in his edition of John of Glastonbury. When the library of Croyland perished by fire in 901 it contained about 700 vols. The library at Peterborough was also rich; from a catalogue of about the end of the 14th century it had 344 vols., with nearly 1700 titles. The catalogues of the library at the monastery of Durham have been printed by the Surtees Society, and form an interesting series. These catalogues with many others afford abundant evidence of the limited character of the monastic collections, whether we look at the number of their volumes or at the nature of their contents. The scriptoria were manufactories of books and not centres of learning. That in which the monks spent the greater part of their time the coldness and scarcity of books remained so great may have been partly, but cannot have been wholly, due to the scarcity of writing materials. It may be suspected that indolence and carelessness were the rule in most monasteries, and that but few of the monks keenly realized the whole force of the sentiment expressed by one of their number in the 12th century—"Claustrum sine armario quasi castrum sine armamentario." Nevertheless it must be

1 The oldest catalogue of a western library is that of the monastery of Fulham, belonging to St Peter's, London. Many early catalogues may be found in the collections of D'Achery, Martene and Durand, and Pez, in the bibliographical periodicals of Naumann and Petzholdt and the Centralblatt f. Bibliothekswissenschaft. The Rev. John Hunter has collected some particulars as to the contents of the English monastic libraries, and Ed. Edwards has printed a list of the catalogues (Libraries and Founders of Libraries, 1865, pp. 448-454). See also G. Becker, Catalogi Bibliothecarum Antiquorum (Bibliotheca Classica, 1835), vol. ii. The collections of the English and German monasteries are included in the Catali-
admitted that to the labours of the monastic transcribers we are indebted for the preservation of Latin literature.

The subject of the evolution of the arrangement of library rooms and fittings as gradually developed throughout medieval Europe should not be passed over. The real origin of library organization in the Christian world, one may almost say the origin of modern library methods, began with the rule of St Benedict early in the 6th century. In the 48th chapter the monks were ordered to borrow a book apiece and to read it straight through.

There was no special apartment for the books in the primitive Benedictine house. After the books became too numerous to be kept in the church they were preserved in armoria, or chests, in the cloister; hence the word armarius, the Benedictine librarian, who at first joined with it the office of precentor. The Benedictine regulations were developed in the stricter observances of the Cluniacs, which provided for a kind of annual report and stocktaking. The Carthusians were perhaps the first to lend books away from the convent; and the Cistercians to possess a separate library official as well as a room specially devoted to books. The observances of the Augustinians contained rules for the binding, repairing, cataloguing and arranging the books by the librarian, as well as a prescription of the exact kind of chest to be used. Among the Premonstratensians or Reformed Augustinians, it was one of the duties of the librarian to provide for the borrowing of books elsewhere for the use of the monks. The Mendicant Friars found books so necessary that at last Richard de Bury tells us with some exaggeration that their libraries exceeded all others.

Many volumes still exist which belonged to the library at Assisi, the parent house of the Franciscans, of which a catalogue was drawn up in 1381. No authentic monastic bookcase can now be found; the doubtful example shown at Bayeux probably contained ecclesiastical utensils.

At the Augustinian priory at Barnwell the presses were lined with wood to keep out the damp and were partitioned off both vertically and horizontally. Sometimes there were recesses in the walls of the cloisters fitted with shelves and closed with a door. These recesses developed into a small windowless room in the Cistercian houses. At Clairvaux, Kirkstall, Fountains, Tintern, Netley and elsewhere this small chamber was placed between the chapter-house and the transept of the church. At Meaux in Holderness the books were lodged on shelves against the walls and even over the door of such a chamber. In many houses the treasury or spenditure contained two classes of books—one for the monks generally, others more closely guarded. A press near the infirmary contained books used by the reader in the refectory. By the end of the 15th century the larger monasteries became possessed of many volumes and found themselves obliged to store the books, hither placed in various parts of the building, in a separate apartment. We now find libraries being specially built at Canterbury, Durham, Citeaux, Clairvaux and elsewhere, and with this specialization there grew up increased liberality in the use of books and learned strangers were admitted. Even at an early date students were permitted to borrow from the Benedictines at St Germain-des-Prés at Paris, of which a later foundation owned in 1513 a noble library erected on the south wall of the cloister, and enlarged and made very accessible to the outer world in the 17th and 18th centuries. The methods and fittings of college libraries of early foundation closely resembled those of the monastic libraries. There was in both the annual giving out and inspection of what we would now call the lending department for students; while the books, fastened by chains—a kind of reference department kept in the library chamber for the common use of the fellows—followed a similar system in monastic institutions.

By the 15th century collegiate and monastic libraries were on the same plan, with the separate room containing books placed on their sides on desks or lecterns, to which they were attached by chains to a horizontal bar. As the books increased the accommodation was augmented by one or two shelves erected above the desks. The library at Cesena in North Italy may still be seen in its original condition. The Laurentian library at Florence was designed by Michelangelo on the monastic model. Another good example of the old form may be seen in the library of Merton College at Oxford, a long narrow room with bookcases standing between the windows at right angles to the walls. In the chaining system one end was attached to the wooden cover of the book while the other ran freely on a bar fixed by a method of double locks to the front of the shelf or desk on which the book rested. The fore edges of the volumes faced the reader. The seat and shelf were sometimes combined. Low cases were subsequently introduced between the higher cases, and the seat replaced by a step. Shelf lists were placed at the end of each case. There were no chairs in the library of the Escorial, erected in 1584, which showed for the first time bookcases placed against the walls. Although chairs were no longer part of the appliances in the newly erected libraries they continued to be used and were ordered in bequests in England down to the early part of the 18th century. Triple desks and revolving lecterns, made by a wooden screw, formed part of the library furniture. The English cathedral libraries were fashioned after the same principle. The old methods were fully reproduced in the fittings at Westminster, erected at a late date. Here we may see books on shelves against the walls as well as in cases at right angles to the walls; the desk-like shelves for the chained volumes (no longer in existence) have a slot in which the chains could be suspended, and are hinged to allow access to shelves below. An ornamental wooden tablet at the end of each case is a survival of the old shelf list. By the end of the 17th century the type of the public library developed from collegiate and monastic prototypes, became fixed as it were throughout Europe (H. R. Tedder, "Evolution of the Public Library," in Trans. of and Int. Library Conference, 1897; 1898).

The first conquests of the Arabians, as we have already seen, threatened hostility to literature. But, as soon as their conquests were secured, the caliphs became the patrons of learning and science. Greek manuscripts were eagerly sought for and translated into Arabic, and colleges and libraries everywhere arose. Bagdad in the east and Cordova in the west became the seats of a rich development of letters and science during the age when the civilization of Europe was most obscure. Cairo and Tripoli were also distinguished for their libraries. The royal library of the Fatimides in Africa is said to have numbered 100,000 manuscripts, while that collected by the Omeyyads of Spain is reported to have contained six times as many. It is said that there were no less than seventy libraries opened in the cities of Andalusia. Whether these figures be exaggerated or not—and they are much below those given by some Arabic writers, which are undoubtedly so—it is certain that the libraries of the Arabians and the Moors of Spain offer a very remarkable contrast to those of the Christian nations during the same period.3

The literary and scientific activity of the Arabians appears to have been the cause of a revival of letters amongst the Greeks of the Byzantine empire in the 9th century. Under Leo the Philosopher and Constantine Porphyrogenitus the libraries of Constantinople woke to renewed life. The compilations of such writers as Stobaeus, Photius and Suidas, as well as the labours of innumerable critics and commentators, bear witness to the activity, if not to the lofty character of the pursuits, of the Byzantine scholars. The labours of transcription were industriously pursued in the libraries and in the monasteries of Mount Athos and the Aegean, and it was from these quarters that the restorers of learning brought into Italy so many Greek manuscripts. In this way many of the treasures of ancient literature had been already

---

1 This subject has been specially treated by J. Willis Clark in several works, of which the chief is a masterly volume, The Care of Books (1901). See also Dom Gasquet, "On Medieval Monastic Libraries," in his Old English Bible (1897).

2 Among the Arabs, however, as among the Christians, theological bigotry did not always approve of non-theological literature, and the great library of Cordova was sacrificed by Almanzor to his reputation for orthodoxy, 978 A.D.
LIBRARIES

The United Kingdom.

State Libraries.—The British Museum ranks in importance before all the great libraries of the world, and excels in the arrangement and accessibility of its contents. The library consists of over 2,000,000 printed volumes and 56,000 manuscripts, but this large total does not include pamphlets and other small publications which are usually counted in other libraries. Adding these together it is probable that over 5,000,000 items are comprised in the collections. This extraordinary opulence is principally due to the enlightened energy of Sir Anthony Panizzi (q.v.). The number of volumes in the printed book department, when he took the keepership in 1837, was only 240,000; and during the nineteen years he held that office about 400,000 were added, mostly by purchase, under his advice and direction. It was Panizzi likewise who first seriously set to work to see that the national library reap all the benefits bestowed upon it by the Copyright Act.

The foundation of the British Museum dates from 1753, when effect was given to the bequest (in exchange for £20,000 to be paid to his executors) by Sir Hans Sloane, of his books, manuscripts; curiosities, &c., to be held by trustees for the use of the nation. A bill was passed through parliament for the purchase of the Sloane collections and of the Harleian MSS., costing £10,000. To these, with the Cottonian MSS., acquired by the country in 1700, was added by George II., in 1757, the royal library of the former kings of England, coupled with the privilege, which that library had for many years enjoyed, of obtaining a copy of every publication entered at Stationers' Hall. This library was of the highest importance, as it enriched the museum with the old collections of Archbishop Cranmer, Henry prince of Wales, and other patrons of literature, while the transfer of the privilege with regard to the acquisition of new books, a right which has been maintained by successive Copyright Acts, secured a large and continuous augmentation. A lottery having been authorized to defray the expenses of purchases, as well as for providing suitable accommodation, the museum and library were established in Montague House, and opened to the public 15th January 1759. In 1763 George III. presented the well-known Thomas collection (in 2230 volumes) of books and pamphlets issued in England between 1640 and 1662, embracing all the controversial literature which appeared during that period. The Library of C. M. became in 1790, one of the trustees, bequeathed his collection of choice books in 1790; and in 1800 Joseph Banks left to the nation his important library of 16,000 vols. Many other libraries have since then been incorporated in the museum, the most valuable being George III.'s royal collection (14,000 vols. of tracts, and 65,250 vols. of printed books, including many of the utmost rarity, which had cost the king about £130,000), which was presented (for a pecuniary consideration; it has been said) by George IV. in 1823, and that of the Right Honourable Thomas Grenville (20,240 vols. of rare books, all in fine condition and binding), which was acquired under bequest in 1846. The Cracherode, Banksian, King's and Grenville libraries are still preserved as separate collections. Other libraries of minor note have also been absorbed in a similar way, and at least since the time of Panizzi, no opportunity has been neglected of making useful purchases at all the British and Continental book auctions.

The collection of English books is far from approaching completeness, but, apart from the enormous number of volumes, the library contains an extraordinary quantity of rarities. Few libraries in the United States equal either in number or value the American books in the museum. The collection of Slavonic literature, due to the initiative of Thomas Watts, is also a remarkable feature. Indeed, in cosmopolitan interest the museum is without a rival in the world, possessing as it does the best library in any European language out of the territory in which the language is vernacular. The Hebrew, the Chinese, and printed books in other Oriental languages are important and represented in large numbers. Periodical literature has not been...
The printed catalogues of the MSS. are—those of the Old Royal Library (1734, 40), which in 1910 was shortly to be superseded by a new one; the Sloane and others hitherto undescribed (1782, 2 vols. 4to); the Cottonian (1817-46); the Harleian (1818, folio); the Lansdowne (1819, folio); the Arundel (1840, folio); the Burney (1840, folio); the Stowe (1846-1866, 4to); the Additional, in periodicals since 1836; the Greek Papyri (1893-1910); the Oriental (Arabic and Ethiopic); Spath's (1838-1862); the Byzantine (1870-1872, 3 pts., 4to); the Ethiopic (1877, 4to); the Persian (1876-1896, 4 vols. 4to); and the Spanish (1876-1895, 4 vols. 8vo); Turkish (1888); Hebrew and Samaritan (1900-1905, 3 vols.); Sanskrit (1903); Hieroglyphic (1898); and other Oriental books, maps, prints and drawings. Perhaps the most useful catalogue of all is the Subject-index to Modern Works issued in 1881-1905 (4 vols.) and compiled by Mr. G. K. Fortescue. The Rules for compiling catalogues in the department of printed books were revised and published in 1906. The building in which the library is housed forms part of the fine group situated in Great Russell Street in central London, and is distinguished by a stately circular reading-room designed by Sydney Smirke from suggestions and sketches supplied by Sir A. Panizzi. This was begun in 1855 and opened in 1857. The room is surrounded by book stores placed in galleries with iron doors, in which, owing to congestion of stock, various devices have been introduced, particularly a hanging and rolling form of auxiliary bookcase. The presses inside the reading-room, arranged in three tiers, contain upwards of 60,000 vols., those on the ground floor (40,000) being books of reference to which readers have unlimited access. The accommodation for readers is comfortable and roomy, each having a portion of table fitted with various conveniences. Perhaps not the least convenient arrangement here is the presence of the staff in the centre of the room, at the service of readers who require aid.

In order to enjoy the privilege of reading at the British Museum, the applicant (who must be over twenty-one years of age) must obtain a renewable ticket of admission through a household address to the principal library. The pressure upon the space at the command of the library has been so great that additional land at the rear and sides of the existing buildings was purchased by the government for the further extension of the museum. The extension of bookshelves, etc., brought the new language to within two years of completion in 1910. The Natural History Museum, South Kensington, a department of the British Museum under separate management, has a library of books on the natural sciences numbering nearly 100,000 vols.

Next in importance to the British Museum, and superior to it in accessibility, is the Library of the Patent Office in Southampton Buildings, London. This is a department of the Board of Trade, and though primarily intended for office use and patentees, it is really a public library freely open to anyone. The only formality required from readers is a signature in a book kept in the entrance hall. After this readers have complete access to the shelves. The library contains considerably over 100,000 vols., and possesses complete sets of the patents specifications of all countries, and a remarkable collection of the technical and scientific periodicals of all countries. The library was first opened in 1855, in somewhat unsuitable premises, and in 1897 it was transferred to a handsome new building.

The reading-room is provided with two galleries and the majority of the books are open to public inspection without the need for application forms. A printed catalogue in author-alphabetical form has been published with supplement, and in addition, separate subject catalogues are issued. This is one of the most complete libraries of technical and scientific literature in the world, and its collection of scientific transactions and periodicals is celebrated.

Another excellent special library is the National Art Library, founded in 1841 and transferred to South Kensington in 1856. It contains about half a million books, prints, drawings and photographs, and is used mostly by the students attending the art schools, though the general public can obtain admission on payment of sixpence per week. A somewhat similar library on the science side is the

The general catalogue of the printed books was at one time kept in MS. in large volumes, but since 1880 the entries have gradually been superseded by the printed titles forming part of the large alphabetical catalogue which was completed in 1900. This important work is arranged in the order of authors' names, with occasional special entries at words like Bible, periodicals and biographical names. It is being constantly supplemented and forms an invaluable bibliographical work of reference.

The catalogue of the MSS. is also very important, of which the most used are the Catalogue of the MSS. of the MS. music has been published. The number of maps is also very large, and a printed catalogue has been issued.

Science Library of the Victoria and Albert Museum, South Kensington, which was founded in 1857. It is a general science collection and incorporates most of the books which at one time were in the Museum of Practical Geology.

The only other state library which is open to the public is that of the Board of Education in Whitbread, which was opened in a new building in 1908. It contains a large collection of works on educational subjects for which a special classification has been devised and printed.

The other state libraries in London may be briefly noted as follows: Admiralty (1700), 40,000 vols.; College of Arms, or Heraldic Office, 18,000 vols.; Colonial Office, c. 15,000 vols.; Foreign Office, c. 80,000 vols.; Home Office (1800) c. 50,000 vols.; House of Commons (1818), c. 50,000 vols.; House of Lords (1834), 50,000 vols.; India Office (1800), c. 86,000 vols.; Kew, Royal Botanic Gardens (1853), 22,000 vols.; and Royal Observatory (Greenwich), 20,000 vols.

Outside London the most important state library is the National Library of Ireland, Dublin, founded in 1877 and incorporating the library of the Royal Dublin Society. It is housed in a handsome building (1869) and contains about 200,000 vols., classified by the Decimal system, and catalogued in various forms. The library of the Museum of Science and Art at Edinburgh, containing over 20,000 vols., was opened to the public in 1890. Practically every department of the Library has a special library of some kind for the use of the staff, and provision is also made for leading libraries and reading rooms in connexion with garrisons, naval depots and other services of the army and navy.

No professional qualifications are required for positions in British state libraries, most of the assistants being merely second-division clerks who have passed the Civil Service examinations. It would be an advantage from an administrative point of view if the professional certificates of the Library Association were adopted by the Civil Service Commissioners as compulsory requirements in addition to their own examination. The official education of a grade of properly trained librarians would tend to improve the methods and efficiency of the state libraries, which are generally behind the municipal libraries in organization and administration.

University and Collegiate Libraries.—The Bodleian Library, Oxford, though it had been preceded by various efforts towards a university library, owed its origin to Sir Thomas Bodley (q.v.). Contributing largely himself, and procuring contributions from others, he opened the library with upwards of 2000 vols. in 1602. In 1610 he obtained a grant from the Stationers’ Company of a copy of every work printed in the country, a privilege still enjoyed under the provisions of the various copyright acts. The additions made to the library soon surpassed the capacity of the room, and the founder proceeded to enlarge it. By his will he left considerable property to the university for the maintenance and increase of the library. The example set by Bodley found many noble imitators. Amongst the chief benefactors have been Archbishop Laud, the executors of Sir Kenelm Digby, John Selden, Sir Thomas (Lord) Fairfax, Richard Gough, Francis Douce, Richard Rawlinson, and the Rev. Robert Mason. The library now contains almost half a million printed vols., and about 41,000 manuscripts. But the number of the volumes, as bound up, conveys a very inadequate idea of the size of the collection. In the department of Oriental manuscripts it is perhaps unequal to any other European library; and it is exceedingly rich in other manuscript treasures. It possesses a splendid series of Greek and Latin editiones princeps and of the earliest productions of English presses. Its historical manuscripts contain most valuable materials for the general and literary history of the country.

The last general catalogue of the printed books was printed in 4 vols. folio (1843-1851). In 1859 it was decided to prepare a new manuscript catalogue on the plan that then in use at the British Museum, which has now been completed in duplicate. In 1910 it was being amended with a view to printing. It is an alphabetical author-catalogue; and the Bodleian, like the British Museum, has no complete subject-index. A slip-catalogue on subjects was, however, in course of preparation in 1910, and there are classified hand-lists of accesses since 1883. There are also printed catalogues of the books belonging to several of the separate collections. The MSS. are in general catalogued according to the collections to which they belong, and they are all indexed. A number of the catalogues of manuscripts have been printed.

In 1860 the beautiful Oxford building known as the “Radcliffe Library,” now called the “Radcliffe Camera,” was offered to the benefactors of the Bodleian by the Radcliffe trustees. The Radcliffe Library was endowed by the famous physician Dr John Radcliffe, who died in 1844, and bequeathed, besides a permanent endowment of £750 a year, the sum of £10,000 for the building. The library was opened in 1740. Many years ago the trustees resolved to confine their purchases of books to works on medicine and natural science. When the university museum and laboratories were built in 1860, the trustees allowed the books to be transferred to the museum. It is used as a storehouse for the more modern books, and it also serves as a reading-room. It is the only room open after the hour when the older building is closed owing to the rule as to the exclusion of artificial light. In 1889 the gallery of the Radcliffe Camera was opened as an addition to the reading-room.

A Staff Kalendar has been issued since 1902, which with a Supplement contains a complete list of cataloguing rules, routine work of the libraries and staff, and useful information of many kinds concerning the library methods.

The Bodleian Library is open by right to all graduate members of the university, and to others upon producing a satisfactory recommendation. No books are allowed to be sent out of the library except by special leave of the curators and convocation of the university. The administration and control of the library are committed to a librarian and board of thirteen curators. The permanent endowment is comparatively small; the ordinary income of £4000 only defrayed from the university chest, is about £10,000.

Within recent years the use of wheeling metal bookcases has been greatly extended, and a large repository has been arranged for economical book storage underground.

The Taylor Institution is due to the benefaction of Sir Robert Taylor, Archbishop, who died in 1778, leaving his property to found an establishment for the teaching of modern languages. The library was established in 1848, and is devoted to the literature of the modern European languages. It contains a fair collection of works on Roman philology, with a special Dante collection, about 1000 Mazarinades and 400 literature pamphlets. The Finch collection, left to the university in 1830, is also kept with the Taylor Library. Books are lent out to members of the university and to others on a proper introduction. The endowment affords an income of £800 to £1000 for library purposes.

The libraries of the several colleges vary considerably in extent and character, although, owing chiefly to limited funds, the changes and growth of all are insignificant. That of All Souls was established in 1438 by the Archbishop of Canterbury and King Henry VII for the��み的 bequest of Christopher Codrington. It devotes special attention to jurisprudence, of which it has a large collection. It possesses 40,000 printed volumes and 300 MSS., and fills a splendid hall 200 ft. long. The library of Brasenose College has a special endowment fund, so that it has, for a college library, the largest endowment of £2000. The library of Christ Church is rich in divinity and topography. It embraces the valuable library bequeathed by Charles Boyle, 4th Earl of Orrery, amounting to 10,000 volumes, the books and MSS. of Archbishop Whate and the Morris collection of Oriental books. The building was finished in 1761, and closely resembles the basilica of Antinous at Rome, now the Dogana. Corpus possesses a fine collection of Aldine, many of them presented by its founder, Bishop Cranmer, with the assistance of the University and of Edward VI, with about 400 MSS. Exeter College Library has 25,000 volumes, with special collections of classical dissertations and English theological and political tracts. The library of Jesus College has few books, but large quantities of pamphlets. Many of these are from the bequest of Sir Leoline Jenkins, who built the existing library. There are also some valuable MSS. The library of Keble College consists largely of theology, including the MSS. of many of its more famous members. Magdalen College has about 22,500 volumes (including many valuable manuscripts and 250 MSS). It has scientific and topographical collections. The library of Merton College has of late devoted itself to foreign modern history. New College Library has about 17,000 printed volumes and 135 MSS. Sir Charles Heneage Lee, the founder, William of Wykeham, Oriel College Library, besides its other possessions, has a special collection of books on comparative philology and mythology, with a printed catalogue. The fine library of Queen’s College is strong in theology, in English and modern European history, and in English county histories. St John’s College Library is largely composed of the literature of theology and jurisprudence before 1750, and possesses a collection of medical books of the 16th and 17th centuries. The newer half of the library building was
erected by Inigo Jones at the expense of Laud, who also gave many printed and manuscript books. The room used as a library at Trinity College formed part of Durham College, the library of which was established by Richard of Bury. Wadham College Library includes a collection of botanical books presented by Dr. Warner in 1775 and a collection of books, relating chiefly to the Spanish Reformers, presented by the executors of Benjamin Wifen. Worcester College Library has of late specially devoted itself to classical archaeology. It is also rich in old plays. The books are arranged in separate buildings to the extent they deserve, and a good deal must be done before they can be said to be as useful and efficient as they might be.

The history of the University Library at Cambridge dates from the earlier part of the 15th century. Two early lists of its contents are preserved, the first embracing 52 vols. dating from about 1425, the second a shelf-list, apparently of 330 vols., drawn up by the outgoing proctors in 1473. Its first great benefactor was Thomas Scott of Rotherham, archbishop of York, who erected in 1475 the building in which the library continued until 1755. He also gave more than 200 books and manuscripts to the library, some of which still remain. The library received other benefactions, but nevertheless appeared "but mean" to John Evelyn when he visited Cambridge in 1654. In 1666 Tobias Rustat presented a sum of money to be invested to buy the choicest and most useful books. In 1715 George I. presented the library of Bishop Moore, which was very rich in early English printed books, forming over 30,000 vols. of printed books and manuscripts. The funds bequeathed by William Worsley and John Manistre, together with that of Rustat, produce at present about £10 a year. The share of university dues appropriated to library purposes amounts to £300 a year. In addition the library is entitled to new books under the Copyright Act. The number of printed volumes in the library cannot be exactly stated, as no recent calculation on the subject exists. It has been estimated at half a million. It includes a fine series of editiones princeps of the classics and of the early productions of the English press. The MSS. of the library amount to 7000 vols., in which are included a considerable number of adversaria or printed books with MS. notes, which form a leading feature in the collection. The most famous of the MSS. is the celebrated copy of the four gospels and the Acts of the Apostles, which is known as Codex Bezae, and which was presented to the university by that Reformer.

A catalogue of the MSS. has been published in 4 vols. (1856-1861), and this has been followed up by the publication of a number of separate catalogues of Persian, Syriac, Hebrew, Chinese, &c. MSS. The library possesses a valuable collection of theological, classical and botanical MSS. It contains a considerable number of engravings of old masters, a collection of music, printed and MS., and a collection of illuminated MSS., chiefly French and Flemish, of the 14th to 16th centuries. The books are not allowed to be taken out. Catalogues and reprints of some of the music and other collections have been published.

The library of Trinity College, which is contained in a magnificent hall built by Sir Christopher Wren, has about 90,000 printed and 150,000 MS. books, and is especially strong in theology, classics and bibliography. It owes to numerous gifts and bequests the possession of a great number of rare books and manuscripts. Amongst these special collections are the Capell collection of early dramatic and especially Shakespearean literature, the collection of Cestari and philosophy bequeathed by Archdeacon Hare, and the Grylls bequest in 1863 of 6000 vols., including many early printed books. There are printed catalogues of the Sanskrit and other Oriental MSS. by Dr. Aufrecht and Professor Palmer, and of the incunabula by the late librarian, Mr.inker. The library is open to all members of the college, and the privilege of using it is liberally extended to properly accredited students. One of the most interesting libraries is that of Trinity Hall, in which the original bookcases and benches are preserved, and many books are seen chained to the cases, as used formerly to be the practice.

None of the other college libraries rivals Trinity in the number of books. The library of Pembroke College received its first books from the foundress. Clare College Library is mostly occupied with Italian and Spanish plays of the end of the 16th century left by George Ruggles. The library of Corpus Christi College first became notable through the bequest of books and MSS. made by Archbishop Parker in 1579. The books are less than 5000 in number, and the additions now made are chiefly in such branches as throw light on the extremely valuable collection of ancient MSS., which attracts scholars from all parts of Europe. There is a printed catalogue of the MSS. of Sir Richard and Lady St. John's College Library of early foundation. A catalogue of the MSS. was printed in 1849, with pictorial illustrations, and a list of the incunabula in 1850. The printed books of King's College include the fine collection bequeathed by Jacob Wassersnake in 1604. The MSS. are almost wholly Oriental, chiefly Persian and Arabic, and a catalogue of them has been printed. Magdalene College possesses the curious library formed by Pepys and bequeathed by him to the college, together with his collections of drawings and of rare British portraits. It is remarkable for its treasures of popular literature and English ballads, as well as for the Scottish manuscript poetry collected by Sir Richard Maitland. The books are kept in Pepys's own cases, and remain just as he left them to himself. The library of Peterhouse is the oldest library in Cambridge, and possesses a catalogue of some 600 or 700 books dating from 1418, in which year it was completed. It is chiefly theological, though it possesses a valuable collection of modern works on geology and natural science, and a unique collection of MS. music. The library of the Fitzwilliam College Library, containing MSS. mainly in theology, classics and Semitic literature, and has a printed class-catalogue. The library of St John's College is rich in early printed books, and possesses a large collection of English historical tracts. Of the MSS. and rare books there is a printed catalogue.

The library of the university of London, founded in 1837, has over 60,000 vols. and includes the Goldsmith Library of economic literature, numbering 30,000 vols.; the British Museum Library, containing over 200,000 vols. of printed books and manuscripts, and a number of valuable MSS. The British Museum is the result of the benefactions of the Duke of Bridgewater, the Duke of Portland, and other friends of literature; there are also a number of manuscript collections, such as the library of the Duke of Devonshire, the library of the Prince of Wales, and the library of the Hon. Sir George Beaumont. The library contains a valuable collection of MSS. and prints, and is open to all students.
vols.; Birbeck College (1823), 12,000 vols.; Congregational Library (1832–1893), 14,000 vols.; the Royal College of Music, containing the library of the defunct Sacred Harmonic Society; Royal Naval College (Greenwich, 1873), 7,000 vols.; St Bartholomew's Hospital (1325), 15,000 vols.; St Paul's School (1509), 10,000 vols.; the Working Men's College (1854), 5000 vols.; and all the Polytechnic schools in the Metropolitan area.

The university library of Durham (1832) contains about 35,000 vols., and the whole Modern English universities—Birmingham, Moxon University College (1880), 27,000 vols.; Leeds, Liverpool (1892), 56,000 vols.; Manchester, Victoria University, which absorbed Owens College (1851), 115,000 vols.; Newcastle-upon-Tyne; Sheffield (1905)—have collections of books. The libraries in connection with theological colleges and public schools throughout England are often quite extensive, and reference may be made to Eton College (1414), 25,000 vols.; Harlebury (1802), 12,000 vols.; Harrow (Vaughan Library), 12,000 vols.; Mill Hill; Oscott College, Erdington (1838), 36,000 vols.; Rugby (1878), 8000 vols.; Stonyhurst College (1794), c. 40,000 vols., &c. The new building for the university of Wales at Bangor has ample accommodation for an adequate library, and the University College at Aberystwith is also equipped with a library.

The origin of the University Library of Edinburgh is to be found in a bequest of his books of theology and law made to the town in 1380 by Clement Little, advocate. This was two years before the foundation of the university, and in 1584 the town council caused the collection to be removed to the college at Aberdeen: they were the foundations. As it was the only library in the town, it contained the manuscripts and benefactions, so that in 1615 it became necessary to erect a library building. Stimulated perhaps by the example of Bodley at Oxford, Drummond of Hawthornend made a large donation of books, of which he printed a catalogue in 1627, and circulated an appeal for assistance from others. In 1678 the library received a bequest of 2000 vols. from the Rev. James NaIrne. In 1709 the library became entitled to the copy privilege, which has since been commuted for a payment of £755 per annum. In 1831 the books were removed to the present library buildings, for which a parliamentary grant had been obtained. The main library hall (100 ft. in length) is one of the most splendid apartments in Scotland. One of the rooms is set apart as a memorial to General Reid, by whose benefaction the library has greatly benefited. Amongst the more recent acquisitions have been the Hill Library, the Phipps collection, the Laing collection of Scottish MSS., the Baillie collection of Catlan MSS. (10,000 vols., of which are of great value), and the Hodgson collection of works on political economy. The library now consists of about 210,000 vols. of printed books with over 2000 MSS. Recently it has been found necessary to make considerable additions to the shelving. The library of the university of Glasgow dates from the 15th century, and numbers George Buchanan and many other distinguished men among its early benefactors. A classified subject-catalogue has been printed, and there is also a printed dictionary catalogue. The annual accessions are about 1500, and the commutation-grant £707. Connected with the university, which is trustee for the public, is the library of the Hunterian Museum, formed by the eminent anatomist Dr William Hunter. It is a collection of great bibliographical interest, as it is rich in MSS. and in fine specimens of early printing, especially in Greek and Latin classics. There are about 200,000 vols. in the library.

The first mention of a library at St Andrews is as early as 1456. The three colleges were provided with libraries of their own about the time of their foundation—St Salvator's 1455, St Leonard's 1512, St Mary's 1537. The University Library was established about 1610 by the Earl of Buchan, and the libraries of the three college libraries were merged in it. The copyright privilege was commuted in 1837. The collection numbers 120,000 vols. exclusive of pamphlets, with about 200 MSS., chiefly of local interest. A library is supposed to have existed before the Reformation. This is a small library, containing very much modern literature, chiefly consisting of older theology, with more or less addition of classical and historical literature. They vary in extent from a few volumes, as at Llandaff or St David's, to 20,000 vols., as at
Durham. Together they possess nearly 150,000 printed and manuscript vols. As a rule, very little is spent upon them, and they are very little used. The cathedral in the old days of the Middle Ages, in which the library of the dean and chapter of Westminster is preserved, is well known from the charming description by Washington Irving in his Sketch Book. There are about 14,000 vols., mostly of old theology and history, including many rare Bibles and other valuable books. The library of the dean and chapter of St Paul's Cathedral was founded in very early times, and is now nearly 22,000 vols. and pamphlets, mainly theological, with a good collection of early Bibles and Testaments, Paul's Cross Sermons, and works connected with the cathedral.

Perhaps the best library of Catholic theology in London is that of the Oratory at South Kensington, established in 1849, and now containing nearly 35,000 vols. The Catholic Cathedral of Westminster, of recent foundation, contains about 22,000 vols. The archiepiscopal library at Lambeth was founded in 1610 by Archbishop Bancroft, and has been enriched by the gifts of Laud, Tenison, Manners Sutton, and others of his successors; it possesses one of the earliest catalogues in the whole hall built by Juxon. The treasures consist of the illustrated MSS., including a number of fine manuscripts of the monks' books; of the latter two catalogues have been issued by Samuel Rolfe Maitland (1792–1866). The MSS. are described in H. J. Todd's catalogue, 1812. The total number of printed books and manuscripts is nearly 45,000.

The library of Christ Church, Oxford, belongs alike to the college and the cathedral, but will be more properly described as a college library. The cathedral library of Durham dates from monastic times, and contains nearly 20,000 vols., of which nearly 9000 are chained, and 11000 unchained. These were added to by Dean Sudbury, the second founder of the library, and Bishop Cosin. The collection has been increased in modern times, and now contains 15,000 vols. It is especially rich in MSS., some of which are of great beauty and value: a catalogue of them was printed in 1825. The library has good topographical and entomological collections. The chapter spend £370 per annum in salaries and in books. The library at York numbers over 60,000 vols., and has been very liberally opened to the public. It is kept in the former chapel of the archbishop's palace, and has many valuable MSS. and early printed books.

The foundation of the library at Canterbury dates probably from the Roman missions in England, A.D. 596, although the library does not retain any of the books then brought over, or even of the books said to have been sent by Pope Gregory to the first archbishop in 601. It is recorded that among Lanfranc's buildings was a new library, and Becket is said to have collected books abroad to present to the library. There were no books printed in England about 1100, and the printed books in the collection, about 110 M. S., and between 6000 and 7000 documents. A catalogue was printed in 1802. The present building was erected in 1867 on part of the site of the monastic dormitory. The library at Lincoln contains about 22,000 vols., in which a catalogue was printed in 1809. It possesses a fine collection of political tracts of the age of Elizabeth, James and Charles I. The present collection at Chichester dates from the Restoration only; that at Ely is rich in books and tracts relating to that period. The Library of the Bishops is chiefly Saxon MSS. of extreme interest, one of them being the gift of Leofric, the first bishop. The treasures of Lichfield were destroyed by the Puritans during the civil war, and the existing library is of later foundation. The library at Norwich is chiefly a public library, and the collection of about 20,000 vols., including the famous Evangelist of St Chad. The collection at Worcester is chiefly modern, and was presented by Dr Sayers. The earlier library at Peterborough having almost wholly perished, the present collection of about 9000 vols. was begun and pillaged by the mob in the riots of 1831. Only about 1200 vols. were saved, many of which were recovered, but few additions have been made to them. At Chester in 1611 Dean Arderne bequeathed a library at the expense of the town, but the present family continued to be the owners of the library, and most of the books are still there. The books are also a good specimen of an oval monastic library; the books are placed in the Lady Chapel, and about 250 choice MSS. are chained to oak desks. The books are ranged with the edges towards upon open shelves, and are not attached, but most interesting " chained " library is that at Wimborne Minster, Dorset, which contains about 280 books in their original condition. The four Welsh cathedrals were supplied with libraries by a deed of settlement in 1700. The largest library, that of Llandaff, has about 1750 vols. The Bibliotheca Leightoniana, or Leightonian Library, founded by Archbishop Leighton in 1684 in Dunblane Cathedral, Scotland, contains about 2000 vols., and is the only cathedral library in Scotland of any historic interest. The library of St Benedict's Abbey, Fort Augustus (1878) with 20,000 vols. is an example of a recent foundation. The public library in St Patrick's Cathedral, Dublin, sometimes called Marsh's Library after its founder, was established in 1701 by a bequest made by Marshal Moore, and was incorporated by an act of parliament in 1707, and endowed by its founder's will in 1713. The building was erected by the founder, and the original oak fittings still remain. There is no provision for additions, and a large proportion of modern books was refused a few years ago on that account. The endowment is too small to allow of the purchase of the funds of the library, so that it still retains the character of a 17th-century library. The books are chiefly theological, and in the learned languages; they include the libraries of Bishop Stillington and Bishop Berkeley, a French refugee, who was the first librarian.

Endowed libraries may be defined as those which have been directly established by the bequests of individuals or corporate bodies, excluding those which have been assisted by donors or are merely named after them. As compared with the United States, the endowed libraries of Britain are few in number, although several are of great importance. London possesses very few libraries which have been endowed by individual donors. The principal are the Bishops' Institute (1891), which was founded out of sundry City of London charities, and now contains about 44,000 vols., and is celebrated for a fine collection of local prints, drawings and maps. It is open free to persons in the east part of the City. The Cripplegate Institute (1856) in Golden Lane, also founded out of charity monies, has three branches—St Bride's Foundation Institute (1800 vols.), jointly; Queen Street, Cheapside, Branch (8000 vols.); and St Luke's Institute (5000 vols.)—and contains 26,000 vols. Lectures and other entertainments are arranged for both of these libraries. Dr Williams' library was founded by the will of an eminent presbyterian divine of that name; it was opened in 1726. The books (2000) are housed in a new building in Gordon Square, completed in 1878. The library of all schools of opinion is represented, and there are special collections of theological books and MSS., the works of Boehme, Law, and other mystical writers. The MSS. include the original minutes of the Westminster Assembly, letters and treaties of Richard Baxter, &c. The St Bride Foundation Technical Reference Library (1859) is a very complete collection of books and specimens of printing and the allied arts, including the library of William Blades and Talbot Baines Reed, and a number of more modern books presented by Mr Passmore Edwards. It contains about 18,000 vols., and is open to all persons interested in printing, lithography, &c, and also to the general public.

The most notable of the English provincial endowed libraries is that of the city of Liverpool, established by Humphrey Chetham in 1653 is still housed in a splendid building, opposite the site where Sir Walter Raleigh was once entertained by Dr Dee. The collection consists largely of older literature, and numbers about 60,000 vols., and 250 MSS., which are kept open to the public, and may be said to have been the first free library in a provincial town. The books in broad classified form were issued in 1791-1863, and there have been supplements since. A remarkable instance of a large library established by private munificence is that of the John Rylands Library at Manchester. It was originally endowed by Mrs E. A. Rylands in memory of her husband, and is contained in a magnificent building designed by Basil Champneys and opened in 1890. The collection was formed largely on the famous Althorp Library, and extends to rare books, valuable MSS., and re- markable collections of early printed books and rare Bibles ever brought together. The present number of volumes is about 115,000, of which over 2500 are incunabula. A short-title catalogue, 3 vols., established by the library, has been published, and a new manuscript dictionary catalogue has been provided. Several valuable special catalogues and descriptive lists have been issued, one of the latest being a special catalogue of the architectural works contained in the library, which is one of the most important in the country.

The William Salt Library, a special Staffordshire library with numerous MSS. and other collections, formed to bring together materials for a history of Staffordshire, was opened to the public in 1837. It is situated in the town of Stafford. It contains nearly 20,000 books, prints and other items.

Other endowed libraries in the English provinces which deserve mention are the Bingham Public Library (1898) at Cirencester; the Guernsey; and the De loin's Library (1894). Hawarden, founded by William Gladstone, the great statesman; and the Shakespeare Memorial Library and theatre (1879) at Stratford-upon-Avon.
The most important endowed library in Scotland is the Mitchell Library in Glasgow, founded by Stephen Mitchell, tobacco-manufacturer (1874), who left £70,000 for the purpose. It was opened in 1877 in temporary premises, and after various changes will soon be transferred to a new building. It contains some very valuable special collections, among which may be mentioned Scottish poetry, Burns' works, Glasgow books and printing, and a choice collection of fine books on art and other subjects given by Mr. Anderson. Among the books of special interest is a large collection of rare reference books for the Glasgow public library system. Another older Glasgow public library, also founded by a tobacco merchant, is Stirling's and Glasgow Public Library (1791), which was endowed by Mr. Stirling in the same year. This library contains 60,000 vols., and is free to reference readers, but a subscription is charged for borrowing privileges. Still another Glasgow institution is Mackenzie's Free Reference Library, established by Reginald A. Rye in 1824, and migrated to Melbourne Chambers (1859), founded by William Chambers, the well-known publisher. The public library of Armagh, Ireland, was founded by Lord Primate Robinson in 1770, who gave a considerable number of books and an endowment. The books are freely available, either on the spot, or by loan on deposit of double the value of the work applied for.

There are many libraries belonging to societies devoted to the study of every kind of subject, and it is only necessary to mention a few of the principal.

Full particulars of most of them will be found in Reginald A. Rye's Libraries of London: a Guide for Students (1910), a work of accuracy and value.

Of the law libraries, that at Lincoln's Inn, London, is the oldest and the largest. It dates from 1497, when John Nethersole, a member of the society, made a bequest of forty marks, part of which was to be devoted to the building of a library for the benefit of the students of the law of England. A catalogue of the printed books was published in 1859 and since supplemented, and the MSS. were catalogued by the Rev. Joseph Hunter in 1837. There are about 100,000 vols. The library of the Inner Temple is known to have existed in 1540, when it was called the 'Inn of Court', and records of books received from benefaction from William Petyt, the well-known keeper of the Tower records. There are now about 60,000 vols., including the pamphlets collected by John Adolphus for his History of England, books on criminal law, books on the law of bills of exchange, etc. The early records of works on jurisprudence made by John Austin. A library in connexion with the Middle Temple was in existence during the reign of Henry VIII., but the date usually assigned to its foundation is 1641, when Robert Skippon, a member of the society, made a bequest of £150. There are now about 50,000 vols. Gray's Inn Library (21,000 vols.) was perhaps established before 1555. In 1699 was made the first catalogue of the books, and the next, still extant, in 1658. The library is now housed in Gray's Inn Hall, at a cost of £5,000, and contains 100,000 vols., including the best collection of private acts of Parliament in England. The library of the Royal Society (1667), now housed in Burlington House, contains over 60,000 vols., of which many are important and on subjects connected with the natural sciences. The Royal Institution (1800) possesses a reference library of 60,000 vols. Some of its early catalogues were in classified form. The London Institution (1805), in the City, is a general library of reference and lending books open to members only, and contains about 150,000 vols., and lectures are given in connexion with the institution. The Royal Society of Arts has a library numbering about 11,000 vols., chiefly the publications of other learned bodies. The Public Record Office, in Chancery Lane, has a library of about 50,000 vols., and the Society of Antiquaries, Burlington House, consisting of nearly 40,000 printed vols. and many MSS. It is rich in early printed books, topography, heraldry and numismatics, and includes a curious collection of manuscript documents relating to the history of the City of London. The remarkable assemblage of lexicographical works formerly belonging to Albert Way.

Of libraries devoted to the natural sciences may be mentioned those of the Royal Society (1660), with 10,000 vols. and maps; the Linnean Society (1788), 35,000 vols.; the Zoological Society (1829), about 31,000 vols. Of libraries associated with medicine there are those of the Royal Society of Medicine (1857), the Royal College of Physicians (1721), the British Medical Association, the British Medical Journal, the Royal College of Surgeons of Edinburgh (1807), 60,000 vols., with a MS. collection of the College; the Royal College of Surgeons of England (1809), 60,000 vols.; the Pharmaceutical Society of Great Britain (1841), about 15,000 vols. Other important London society libraries are - the Royal Geographical Society (1830), 30,000 vols., and numerous maps in a special room, and the public libraries of the Royal Colonial Institute (1868), 70,000 vols. of British colonial literature; the Royal United Service Institution, Whitehall (1821), has 32,000 vols. on military and naval subjects and a museum. Large and interesting collections of books are owned by the British and Foreign Bible Society, the Institution of Civil Engineers, the Institution of Electrical Engineers (containing the Ronalds Library), the Royal Academy of Fine Arts, the Society of Architects, and practically every other working society in London.

The English provincial libraries connected with societies or learned bodies are mostly attached to those concerned with law, medicine, and the arts. Among the most important is that belonging to the quarters of national societies being in London to some extent accounts for the comparatively small number of these special libraries in the provinces.

The other important libraries of this description outside London are situated in Scotland and Ireland, and one at least is practically a national collection.

The principal library in Scotland is that of the Faculty of Advocates, Edinburgh, who in 1868 appointed a committee of reference. In 1864 the first librarian was appointed, and the library appears to have made rapid progress, since it appears from the catalogue that the number of books was double what it was valued at upwards of £1,100,000, exclusive of donations. In the year 1700, the rooms in the Exchange Stairs, Parliament Close, in which the library was kept, being nearly destroyed by fire the books were removed to the house of a bookseller, where it has ever since remained. The library retains the copyright privilege conferred upon it in 1709. Of the special collections the most important are the Arstorg collection of old Spanish books, the Temple of the Faculty of Advocates, and the Faculty collection, consisting of about 120 vols., relating chiefly to the history and antiquities of the northern nations, and including some rare books on old Scottish poetry; the Dietrich collection of over 100,000 German and Dutch books, which contains the writings of Luther and Melancthon, purchased for the small sum of £80; and the Colombe collection.

The Faculty appears early to have turned their attention to the collection of MSS. and this department of the library now numbers about 3000 vols. Many of them are of great interest and value, especially for the civil and ecclesiastical history of Scotland before and after the Reformation. There are about thirteen monastic chartularies which escaped the destruction of the religious houses to which they belonged. The MSS. relating to Scottish church history include the collections of Spottiswoode, Wodrow and Calderwood. The Wodrow collection consists of 154 vols. and includes correspondences extant from Sir James Balfour's collection, the Balfour papers consist largely of original state papers, and include many interesting royal letters of the times of James V., Queen Mary and James VI. The Balfour papers, numbering over 150 vols., consist of letters sent between the two. The Robert Bruce papers, containing 75 vols., contain collections to illustrate the genealogy of Scottish families. There are about one hundred volumes of Iceland MS., purchased in 1825 from Professor Finn Magnusson, and some Persian and Sanskrit, with a few classical, manuscripts. The department has some interesting treasures of old poetry, extending to 73 vols. The most important are the Barnett MS., in 2 vols., folio, by George Barnett in 1598, and the Auchinleck MS., a collection of ancient English poetry, named after Alexander Bowell of Auchinleck, who presented it in 1774.

The first catalogue of the printed books was compiled in 1692, and another in 1761, and at that date the library contained about 600 vols. under the care of Ruddiman in 1742. In 1835 the late Mr. Hakluyt commenced a catalogue, which has been printed in 6 vols. 4to., with a supplement, and includes all the printed books in the library at the end of 1871, containing 500 vols. The library, managed by a committee of staff, under a board of six curators, is easily accessible to all persons engaged in literary work, and now contains about 500,000 vols. and 10,000 MSS. and MSS. to the Signet was established by the Society at Edinburgh in 1755. At first it consisted of law books exclusively, but in 1788 they began to collect the best editions of works in other departments of literature. During the librarianship of Mr. James Balfour, the library was greatly augmented, and in 1812 the library was removed to the new hall adjoining the Parliament House. In 1834 the upper hall was devoted to the collection. This is a magnificent apartment 124 ft. long and costing £40,000. It contains over 100,000 vols. and includes some fine specimens of early printing, as well as many other rare and costly works. It is especially rich in county histories and British topography and antiquities. A catalogue of the library was published in 1843 by the late Mr. David James.
Libraries. The books are lent out to the writers and to strangers recommended by them. The library of the Royal Irish Academy at Dublin was established on the foundation of the Academy in 1785 for the purpose of promoting the study of science, literature and antiquities in Ireland. The library contains nearly 50,000 volumes, of which there is a large collection of MSS. and books relating to the history, ancient language, and antiquities of Ireland. They include the Bertram collection, acquired partly by public subscription in 1828, and partly by purchase, as well as articles which are freely open in a proper introduction. The publication of Irish MSS. in the library was begun in 1780, and has since continued; the general catalogue is in manuscript form.

The Lyceum, which was founded, pursuant to a bequest of books and legal MSS. under the will of Mr Justice Robinson in 1787, to form the nucleus of a library for law students. It is partly supported from the funds of the bursers, but partly also by a treasurer granted in lieu of the fromage privilege. It is needless to describe the other society libraries, as most of them are in annuals like the Literary Year-book and similar publications, with statistics of stocks, issues, etc., brought up to date.

Proprietary and subscription libraries were at one time more numerous than now, as, owing to the steady advance of the municipal library, the minor subscription libraries have been gradually extingushed. A striking example of this is furnished by the number of 80,000 libraries which are in operation all over the country. In most cases these have been handed over to the local authorities by the owners to form the nucleus of the public rate-supported library, and in this way the older libraries have been preserved and valuable aid has been given to the popular library movement. Some material to the mechanics' institutes are the libraries established in connexion with various co-operative societies in the north of England. Together with working men's club libraries, there must be nearly 100 libraries of the class just mentioned, ranging in size, from a few hundred vols. to 30,000 or 40,000 vols. The affiliated clubs of the Working Men's Club and Institute Union possess among them over 100,000 vols.

Among subscription libraries, the London Library stands first in order of importance. It was founded in 1841 as a lending library for the use of scholars, and Dean Milman, Sir G. C. Lewis, W. E. Gladstone, Thomas Carlyle, Henry Hallam, Ewart and other eminent men took part in its formation. By means of a moderate subscription, funds were raised for the purchase of books on general subjects, which now amount to about 250,000 vols. Of these elaborate and excellent author and subject catalogues have been printed. The last is valuable as a classified guide to the contents of the library.

Some mention should be made also of the more important subscription or proprietary libraries, which were formed for the most part in the latter half of the 18th century. The earliest circulating library in the British Empire was established in the New York in 1754. The first in Birmingham was opened by Hutton in 1757. The idea of a proprietary library appears to have been first carried out at Liverpool in 1758. The library then formed still flourishes at the Liverpool, and possesses a collection of 55,000 vols. and an income of £100 a year. In 1760 a library was formed at Warrington, which has been merged in the Warrington Museum. The Leeds library was established in 1768, and now has 64,000 vols. In 1772 the Bristol museum was formed, and was supported by subscription. The Stockton and Lindesley among its earlier members. It has now been merged in the reference collection of the Bristol public libraries. The Birmingham (old) library was formed in 1779, and its rules were drawn up by William Henry Vickers. The subscription library was formed in 1789, and its subscription was supported by a government grant and is now numbers about 75,000 vols. of books in all departments of literature, and is especially rich in well-bound and fine copies of works on the fine arts, archology, topography and history. The pamphlets, of which there is a complete printed catalogue, as well as of the books, form a remarkable series, including those collected by Gibbon and Mackintosh. Next comes the Reform Club, with about 60,000 vols., chiefly in belles-lettres, with a fair proportion of parliamentary and historical works. The National Liberal Club, containing the Gladstone Library, has about 45,000 vols., and may be used occasionally by non-members. The Oxford and Cambridge Club has 30,000 vols., in general and classical literature. At the Garrick there is a small dramatic collection; and the (Senior) United Service Club, besides a number of books on professional subjects, possesses the fine library which formerly belonged to Dugald Stewart.

Other London clubs which possess libraries are the Carlton with 25,000 vols.; the Constitutional with 12,000 vols.; Grand Lodge of Freemasons, 10,000 vols.; Holland House, 10,000 vols.; University, 8,000 vols.; and the Inns of Court, 6,000 vols. In the provinces and in Scotland and Ireland, every club of a social character has a reading-room, and in most cases a library is attached.

The first act of parliament authorizing the establishment of public libraries in England was obtained by William Ewart, M.P. for the Dumfries Burghs, in 1850. This arose out of the report of a special parliamentary committee appointed to enquire into the management of the British Museum in 1835, and a more general report on libraries in 1849, at which much evidence was submitted to prove the necessity for public libraries. Ewart brought in his committee and also, in 1845, procured an act for "encouraging the establishment of museums in large towns." Neither the 1845 nor 1850 acts proved effective, owing chiefly to the limitation of the library rate to 14d. in the £ of rental, which produced in most cases an insufficient revenue. In 1853 the Library Act of 1850 was extended to Ireland and Scotland, and in 1854 Scotland obtained an act increasing the rate limit from 14d. to 1s. in the £. In 1855 Ireland also obtained a penny rate, and later in the same year England obtained the same power by an act which remained the principal library act, with some intermediate amendments, till 1892, when a Public Library Consolidation Act was passed. In the following year, 1893, the power of adopting the acts, or putting them in operation, was transferred from the ratepayers to the local authority, save in the case of rural parishes and the metropolitan vestries. By the London Government Act of 1899, however, the metropolitan boroughs were given the power of adopting the acts of 1829-1893 without consulting the ratepayers, so that as the law at present stands, any urban district can put the public libraries acts in force without reference to the voters. Rural parishes are still required by the provisions of the Local Government Act 1894 to adopt the 1892 Library Act by means of a parish meeting, or if a poll is demanded, by means of a poll of the voters.

The main points in British library legislation are as follows:

(a) The acts are permissive in character and not compulsory, and can only be put in force by a vote of a majority of members in an urban district or city, or of a majority of voters in rural districts.

(b) The amount of rate which can be collected is limited to one penny in the pound of the rateable value of the district, though in some towns power has been obtained by special legislation for borrowing money to increase the amount to 2d. In a few cases, as at Birmingham, no limit is fixed. The incomes produced by the penny in the pound range from less than £10 in a rural district to over £2,500 in a large city.

The municipal libraries are managed by committees appointed by the local authorities, who, if so disposed, delegate to them all their powers and duties under section 15 of the act of 1892. The local authorities in England have also power to appoint persons on the committee from among the ratepayers, and in Scotland the principal act of 1887 committees are to consist of one-half councillors and one-half non-councillors, not to exceed a total of 20, and these committees become independent bodies not subject to the councils. Glascow has carried out of this arrangement by means of a special act. In Ireland, committees are appointed much on the same system as in England.

(d) Power is given to provide libraries, museums, schools for scientific and technical purposes for all purposes, is impossible to carry on so many departments with the strictly limited means provided by the acts, although some towns have attempted to do so. The Museums and Galleries Act of 1891 enables an urban district of over 25,000 inhabitants to one-half of its income or rate for the purpose of establishing a museum or art gallery, and many places which have established museums or art galleries under the provisions of the Libraries Acts have also adopted the Museums Act in order to increase their revenues.

(e) The regulation and management of public libraries are entrusted to the library authority, which may either be the local
authority, or a committee with a full or partial delegation of powers. The library authority can buy books, periodicals, specimens of art and science, and make all necessary rules for the proper working of the libraries. The staff can be appointed, and arrangements may be made with local authorities for the joint use of some libraries. Buildings may also be erected, and money borrowed for the purpose on the security of the local rates. These are the main provisions of the public library legislation of the United Kingdom as at present. Amongst other and more local authorities are presented the abolition or raising of the rate limitation, and some clearer definitions as to powers which can be exercised, as for example, the right to spend money on lectures. The rate limitation is the most serious difficulty, and it is the smaller towns to a much greater degree than large cities or areas.

Between 1850 and 1910 about 630 local government areas of all kinds adopted the Public Libraries Acts. Of these a considerable number had in 1910 not yet put the acts in operation, whilst the London Government Act 1892, by joining various previously independent vestries or boards, extinguished about 23 library areas. The Metropolitan County of London in 1910 comprised 25 library areas, or counting also the City, 26, and only Murtlebone, Bethnal Green and parts of Finsbury and Paddington remained unprovided. Practically every large city or district council has adopted the Public Libraries Acts or obtained special legislation, and the number of new public libraries has increased from one in 1835 to 91,000 in 1910. The Metropolitan Library Acts, 1850, 1864, 1868, 1876, 1892, 1896, 1900, and 1910, were passed by the London County Council, but not all the metropolitan boroughs have been provided with a public library. London, however, is an exception, and the number of municipal libraries in London is 1,200, of which 700 are in the City of London. The City of London is the only one of the 54 municipalities in England with a public library, and the City of London Library is the largest in the country, with a total of 10,000,000 volumes. It has a staff of 1,200 and is open to the public 24 hours a day. The City of London Library is also one of the oldest public libraries in the world, having been founded in 1204.

The library system of the United Kingdom is divided into two main parts: the national and the municipal. The national library system includes the British Library, the National Library of Scotland, and the National Library of Wales. The British Library is the largest library in the world, with over 150 million items. The municipal library system is made up of local authority libraries, which are funded by local government and are open to the public.

Of the 54 municipalities in England, 42 have libraries. The largest library is in London, with 700 libraries. The smallest is in Shetland, with only one library. The average number of books in a municipal library is 5,000.

In addition to the public libraries, there are also private libraries, such as the British Library, the National Library of Scotland, and the National Library of Wales. The British Library is the largest library in the world, with over 150 million items. The National Library of Scotland is the largest library in Scotland, with over 10 million books. The National Library of Wales is the largest library in Wales, with over 2 million books.

The library system of the United Kingdom is divided into two main parts: the national and the municipal. The national library system includes the British Library, the National Library of Scotland, and the National Library of Wales. libraries use the card, sheaf and other systems which allow constant and infinite intercalation coupled with economy and ease in making additions.

The idea of using separate slips or cards for cataloguing books, in order to obtain complete powers of arrangement and revision is not new, having been applied during the French revolutionary period to the cataloguing of libraries. More recently the system has been applied to various commercial purposes, such as bookkeeping by what is known as the "loose-leaf ledger," and in this way greater public attention has been directed to the possibilities of adjustable methods both in libraries and for business. The card system is perhaps the most generally used at present, but many improvements in the adjustable binders, called by librarians the "sheaf system," will probably result in this latter form becoming a serious rival. The card method consists of a see view of many librarians outweighs the undoubtedly valuable qualities of comparative safety and multiplication of topics possessed by the printed form. There are many different forms of both card and sheaf systems, and practically every library now uses one or other of them for cataloguing or indexing purposes.

One other modification in connexion with the complete printed catalogue has been tried with success, and seems worthy of brief mention. After a complete manuscript catalogue has been provided in sheaf form, a select or eclectic catalogue is printed, comprising all the most important books in the library and those that represent special subjects. This, when supplemented by a printed list or bulletin of additions, seems to supply every need.

The most striking tendency of the modern library movement is the great increase in the freedom allowed to readers both in reference and lending departments. Although access to the shelves was quite a common feature in the older subscription libraries, and in state libraries like the British Museum and Patent Office, it is only within comparatively recent years that lending library borrowers were granted a similar privilege.

Most municipal reference libraries grant access to a large or small collection of books, and at Cambridge, Birmingham and elsewhere in the United Kingdom, the practice is of long standing. So also in the United States, practically every library has its open shelf collection. On the continent of Europe, however, this method is not at all general, and books are guarded with a jealousy which in many cases must militate against their utility. The first "safe-guarded" open access municipal lending library was opened at Clerkenwell (now Finsbury), London, in 1893, and since then over one hundred cities and districts of all sizes in Britain have adopted the system. The British municipal libraries differ considerably from those of the United States in the safeguards against abuse which are employed, and the result is that their losses are insignificant, whilst in America they are sometimes enormous. Patwacket and Cleveland in America were pioneers to some extent of the open shelf system for lending libraries, but the methods employed had little resemblance to the safe-guarded system of British libraries.

The main features of the British plan are: exact classification; class; shelf and book guiding; the provision of automatic locking wickets to regulate the entrance and exit of borrowers, and the rule that borrowers must be registered before they can obtain admission. This last rule is not always current in America, and in consequence abuses are liable to take place. The great majority of British and American libraries, whether allowing open access or not, use cards for charging or registering books loaned to borrowers. In the United Kingdom a considerable number of places still use indicators for this purpose, although this mechanical method is gradually being restricted to fiction, save in very small places.

Other activities of modern libraries which are common to both British and American are courses of lectures, book exhibitions, work with children, provision of books for the blind and for foreign residents, travelling libraries and the education of library assistants. In many of the recent buildings, especially in those erected from the grant of municipal or national revenue, provision has been made for toys and children are provided. Courses of lectures in connexion with the Liverpool and Manchester public libraries date from 1886, but during the years 1900-1910 there was a very great extension of this work. As a rule these courses are intended to direct attention to the literature of the subjects treated, as represented in the libraries, and in this way a certain amount of mutual advantage is secured. In some districts the libraries work in association with the education authorities, and thus it is rendered possible to keep schools supplied with books, over which the teachers are able to exercise supervision. This connexion between libraries and schools is much less common in the United Kingdom than in the British colonies and the United States, where courses of lectures, book exhibitions, and national system of education. Excellent work has been accomplished within recent years by the Library Association in the training of librarians, and it is usual for about 300 candidates to come forward for annual examinations. There is, however, no examination for the possession of municipal certificates and diplomas are awarded. The profession of municipal librarian is not by any means remunerative as compared with employment in teaching in the Civil Service, and until the library rate is increased there is little hope of improvement.

The usefulness of public libraries has been greatly increased by the work of the Library Association, founded in 1877, during the first International Library Conference, held at Paris in October 1877. A charter of incorporation was granted to the association in 1898. It holds monthly and annual meetings, publishes a journal, conducts examinations, issues certificates, holds classes for instruction, and has been so far the only body able to introduce in the public library the Library Assistants Association (1895) publishes a journal. A second International Library Conference was held at London in 1897, and a third at Brussels in 1910. Library associations have been started in most of the larger cities of Europe during the last ten years, unmuch of them limiting themselves to the larger and more important in existence, was established in 1876. These associations are giving substantial aid in the development and improvement of library methods and the status of librarians, and it is certain that their influence will in time produce a more scientific and valuable type of library than at present generally exists.

British Colonies and India.

The majority of the British Colonies and Dependencies have permissive library laws on lines very similar to those in force in the mother country. There are, however, several points of difference which are worth mention. The rate limit is not so strict in every case, and an effort is made to bring the libraries into closer relations with the educational machinery of each colony.

There is, for example, no rate limit in Tasmania, and South Australia may raise a library rate equivalent to £d. in the £, although, in both cases, owing to the absence of large towns, the legislation has not been adopted. In Africa, Australia and Canada the governments make grants to public libraries up to a certain amount, on condition that the reading-rooms are open to the public, and some of the legislatures are even in closer touch with the libraries. The Canadian and Australian libraries are administered more or less on American lines, whilst those of South Africa, India, etc., are managed on the plan followed in England.

Africa.

There are several important libraries in South Africa, and many small town libraries which used to receive a government grant equal to the subscriptions of the members, but in no case did such grants exceed £50 for any one library in one year. These grants fluctuate considerably owing to the changes and temper of successive governments, and since the last war they have been considerably reduced everywhere. One of the oldest libraries is the South African Public Library at Cape Town established in 1818, which enjoys the copyright-privilege of
receiving a free copy of every publication issued in Cape Colony. This library contains the great collection of colonial books bequeathed by Sir George Grey. The libraries of the various legislatures are perhaps the best supported and most important, but mention should be made of the public libraries of Port Elizabeth, Cape Colony, which published an excellent catalogue, and the public libraries at Kimberley; Durban, Natal; Bloemfontein, Orange River Colony; Bulawayo, Rhodesia; Johannesburg, Transvaal; and the public and university libraries at Pretoria. None of the libraries of North Africa are specially notable, although there are considerable collections at Cairo and Algiers.

**Australasia.**

All the public libraries, mechanics’ institutes, schools of arts and similar institutes receive aid from the government, either in the form of grants of money or boxes of books sent from some centre. The public library of New South Wales, Sydney (1869), which includes the Mitchell Library of over 50,000 vols., now possesses a total of nearly 250,000 vols., and circulates books to country libraries, lighthouses and teachers’ associations to the number of about 20,000 vols. per annum. The public library of Victoria, Melbourne (1853), with about 220,000 vols., also sends books to 443 country libraries of various kinds, which among them possess 750,000 vols., and circulate annually considerably over 2½ million vols. The university library at Melbourne (1853) has over 20,000 vols., and the libraries connected with the parliament and various learned societies are important. The public library of South Australia, Adelaide, has about 75,000 vols., and is the centre for the distribution of books to the institutes throughout the colony. These institutes possess over 325,000 vols. There is a good public library at Brisbane, Queensland, and there are a number of state-aided schools of arts with libraries attached. The Library of Parliament in Brisbane possesses over 40,000, and the Rockhampton School of Arts has 10,000 vols. Western Australia has a public library at Perth, which was established in 1887, and the small town institutes are assisted as in the other colonies.

Tasmania has several good libraries in the larger towns, but none of them had in 1910 taken advantage of the act passed in 1867 which gives municipalities practically unlimited powers and means as far as the establishment and maintenance of public libraries are concerned. At Hobart the Tasmanian Public Library (1849) is one of the most important, with 25,000 vols.

New Zealand is well equipped with public libraries established under acts dating from 1869 to 1877, as well as subscription, college and government libraries. At Auckland the Free Public Library (1886) has 50,000 vols., including Sir George Grey’s Australasian collection; the Canterbury Public Library, Christchurch (1874), has 40,000 vols.; the University of Otago Library, Dunedin (1872), 10,000 vols.; and the public library at Wellington (1893) contains 20,000 vols.

**India and the East.**

Apart from government and royal libraries, there are many college, society, subscription and others, both English and oriental. It is impossible to do more than name a few of the most notable. Lists of many of the libraries in private hands including descriptions of their MS. contents have been issued by the Indian government. At Calcutta the Sanskrit college has 1632 printed Sanskrit volumes and 2709 Sanskrit MSS., some as old as the 14th century; there is also a large collection of Jain MSS. The Arabic library attached to the Arabic department of the Madrasa was founded about 1781, and now includes 731 printed volumes, 143 original MSS. and 151 copies; the English library of the Anglo-Persian government dates from 1854, and extends to 3254 vols. The library of the Asiatic Society of Bengal was founded in 1784, and now contains 15,000 printed vols., chiefly on eastern and philological subjects, with a valuable collection of 9500 Arabic and Persian MSS.

At Bombay the library of the Bombay branch of the Royal Asiatic Society, established in 1804 as the Literary Society of Bengal, is now an excellent general and oriental collection of 75,000 printed vols. and MSS., described in printed catalogues. The Moolah Poroze Library was bequeathed for public use by Moolah Poroze, head priest of the Pandis of the Kidmi sect in 1831, and consisted chiefly of MSS., in Arabic and Persian on history, philosophy and astronomy; some additions of English and Gujarati works have been made, as well as of European books on Zoroastrianism. The Native General Library (1845) has 11,000 vols., and there are libraries attached to Elphinstone College and the university of Bombay.

The library of Tipuoo Sahib, consisting of 2000 MSS., fell into the hands of the British, and a descriptive catalogue of them by Charles Stewart was published at Cambridge in 1809, 4to. A few were presented to public libraries in England, but the majority were placed in the college of Fort William, then recently established. The first volume, containing Persian and Hindustani poetry, of the Catalogue of the Libraries of the King of Oudh, by A. Sprenger, was published at Calcutta in 1854. The compiler shortly afterwards left the Indian service, and no measures were taken to complete the work. On the annexation of the kingdom in 1856 the ex-king is believed to have taken some of the most valuable MSS. to Calcutta, but the largest portion was left behind at Lucknow. During the siege the books were used to block up windows, &c., and those which were not destroyed were abandoned and plundered by the soldiers. A few, however, were rescued and sold by auction, and of these some were purchased for the Asiatic Society of Bengal.

Perhaps the most remarkable library in India is that of the raja of Tanjore, which dates from the end of the 16th or beginning of the 17th century, when Tanjore was under the rule of the Telugu Nâiks, who collected Sanskrit MSS. written in the Telugu character. In the 18th century the Maharrattas conquered the country, and since that date the library increased but slowly. By far the greater portion of the store was acquired by Sharâbhajî Râjâ during a visit to Benares in 1820–1830; his successor Sîvâji added a few, but of inferior value. There are now about 18,000 MSS. written in Devanâgarî, Nandinâgarî, Telugu, Kamudâ, Granth, Malayalam, Bengali, Panjabi or Kashmiri, and Urdu; 8000 are on palm leaves. Dr Burnell’s printed catalogue describes 12,375 articles.

The Royal Asiatic Society has branches with libraries attached in many of the large cities of India, the Straits Settlements, Ceylon, China, Japan, &c. At Rangoon in Burma there are several good libraries. The Raffles Library at Singapore was established as a proprietary institution in 1844, taken over by the government in 1890, and the present directorship was established by an ordinance passed in 1878. It now contains about 35,000 vols. in general literature, but books relating to the Malay peninsula and archipelago have been made a special feature, and since the acquisition of the collection of J. R. Logan in 1879 the library has become remarkably rich in this department. In Ceylon there is the Museum Library at Colombo (1877), which is maintained by the government, and there are many subscription and a few oriental libraries.

**Canada.**

The public libraries of the various provinces of Canada have grown rapidly in importance and activity, and, assisted as they are by government and municipal grants, they promise to rival those of the United States in generous equipment. Most of the library work in Canada is on the same lines as that of the United States, and there are no special points of difference worth mention. The library laws of the Dominion are embodied in a series of acts dating from 1851, by which much the same powers are conferred on local authorities as by the legislation of Britain and the United States. An important feature of the Canadian library law is the close association maintained between schools and libraries, and in some provinces the school libraries are established by the school and not the library laws. There is also an important extension of libraries to the rural districts, so that in every direction full provision is being made for the after-school education and recreation of the people.
The province of Ontario has a very large and widespread library system of which full particulars are given in the annual reports of the minister of education. The library portion has been printed separately, and with its illustrations and special articles forms quite a handsome volume. There are now about 1,039 public libraries described as free and not free, and of these 1,371 free and 234 not free in 1909. The free libraries possessed 775,976 vols. and issued 2,421,049 vols. The not free libraries, most of which receive a legislative grant, which is payable in arrears, possessed 40,000 vols. and issued 650,826 vols. This makes a grand total of 1,278,855 vols. in municipal and assisted subscription libraries without counting the university and other libraries in the province. The most important other libraries in Ontario are: Queen's Library, Ottawa, about 120,000 vols.; University of Toronto, about 100,000 vols.; University of Ottawa, 35,000 vols.; Legislative Library of Ontario, 50,000 vols. The Public (municipal) Library of Toronto has now over 152,000 vols.

In the province of Quebec, in addition to the state-aided libraries there are several large and important libraries, among which may be mentioned the Fraser Institute, Montreal, 40,000 vols.; McGill University, 28,000 vols.; Montreal, 30,000 vols.; University of Quebec, 28,000 vols.; and the Library of the Legislature (1909); 100,000 vols. In the western provinces, the Public libraries, government and college, have been formed, but none of them are as old and important as those in the eastern provinces.

In Nova Scotia there are now 279 cases of books circulating among the public within the province, above 30,000 vols., and in addition about 1,280 vols. were stocked for the use of rural school libraries. The rural school libraries of Nova Scotia are regulated by a special law, and a little handbook has been printed, somewhat similar to that published by the New York education department. The following lists of libraries. The Legislative Library at Halifax contains nearly 25,000 vols., and the Dalhousie University (1868), in the same town, contains about 20,000 vols. The Legislative Library of Prince Edward Island, Charlottetown, contains nearly 10,000 vols., and the other libraries in the province are very important. The consequence are those in the West Indian Islands. The Institute of Jamaica, Kingston (1879) has about 15,000 vols.; the Trinidad Library (1841), recently revised and catalogued, 23,000 vols.; and the Antigua Library, Montserrat, 2,000 vols., and St. Vincent Library, 1,000 vols.

Wheatley, How to Catalogue a Library (1889).

United States of America.

The libraries of the United States are remarkable for their number, size, variety, liberal endowment and good administration. The total number of libraries with over 1000 vols. was 1,783 in 1900, including those attached to schools and institutions, and in 1910 there were probably at least 15,000 libraries having 1000 vols. and over. It is impossible to do more than glance at the principal libraries and activities, where the field is so immense, and a brief sketch of some of the chief federal, state, university, endowed and municipal libraries will therefore be presented.

The Library of Congress was first established in 1800 at Washington, and was burned together with the Capitol by the British army in 1814. President Jefferson's books were purchased to form the foundation of a new library, which continued to increase slowly until 1831, when all but 20,000 vols. were destroyed by fire. From this time the collection has grown rapidly, and now consists of about 1,800,000 vols. In 1866 the library of the Smithsonian Institution, consisting of 40,000 vols., chiefly in natural science, was transferred to the Library. The library is specially well provided in history, jurisprudence, the political sciences and American. Since 1852 the law collections have been constituted into a special department. This is the national library. In 1870 the registry of copyrights was transferred to it under the charge of the librarian of Congress, and two copies of every publication which claims copyright are required to be deposited. Cards for these are now printed and copies are sold to other libraries for an annual subscription fixed according to the number taken. The building in which the library is now housed was opened in 1897. It covers 33 acres of ground, contains 10,000,000 cub. ft. of space, and has possible accommodation for over 4 million vols. Its cost was $6,500,000, or including the land, $7,500,000. It is the largest, most ornate and most costly building in the world yet erected for library purposes. Within recent years the appropriation has been largely increased, and the bibliographical department has been able to publish many valuable books on special subjects. The A.L.A. Catalog (1904) and A.L.A. Portrait Index (1906), may be mentioned as of especial value. The classification of the library is being gradually completed, and in every respect this is the most active government library in existence.

Other important federal libraries are those attached to the following departments at Washington: Bureau of Education (1868); Geological Survey (1872); House of Representatives, Senate, Patent Office (1836); Senate (1868); Surgeon General's Office (1876), with an elaborate analytical printed catalogue of worldwide fame.

Although the state libraries of Pennsylvania and New Hampshire are known to have been established as early as 1777, it was not until some time after the revolution that any general tendency was shown to form official libraries in connexion with the state system. It is especially within the last thirty years that the number of these libraries has so increased that now every state and territory possesses a collection of books and documents for official and public purposes. These collections depend for their increase upon annual appropriations by the several states, and upon a systematic exchange of the official publications of the general government and of the several states and territories. The largest is that of the state of New York at Albany, which contains nearly 500,000 vols., the state of Massachusetts at Boston, and the Library of Congress. Printed and MS. card catalogues have been issued. The state libraries are libraries of reference, and only members of the official classes are allowed to borrow books, although any well-behaved person is admitted to read in the libraries.

The earliest libraries formed were in connexion with educational institutions, and the oldest is that of Harvard (1638). It was destroyed by fire in 1764, but active steps were at once taken for its restoration. From that time to the present, private donations have been the great resource of the library. In 1840 the collection was removed to Gore Hall, erected for the purpose with a noble bequest from Christopher Gore (1758-1820), formerly governor of Massachusetts. There are also ten special libraries connected with the different departments of the university. The total numbers of vols. in all these collections is over 800,000. There is a MS. card-catalogue in two parts, by authors and subjects, which is accessible to the readers. The only condition of admission to use the books in Gore Hall is respectability; but only
members of the university and privileged persons may borrow books. The library of Yale College, New Haven, was founded in 1701, but grew so slowly that, even with the 1000 vols. received from Bishop Berkeley in 1733, it had only increased to 4000 vols. in 1756, and some of these were lost in the revolutionary war. During the 19th century the collection grew more speedily, and now the library numbers over 550,000 vols.

Other important university and college libraries are Amherst College, Mass. (1821), 93,000 vols.; Brown University, R.I. (1765), 150,000 vols.; Columbia University, N.Y. (1750), 430,000 vols.; Cornell University, N.Y. (1868), 350,000 vols.; University of California at Berkeley, Calif. (1868), 150,000 vols.; Johns Hopkins University, Baltimore (1876), 200,000 vols.; Lehigh University, Pa. (1863), 150,000 vols.; Leland Stanford University, Calif. (1891), 113,000 vols.; Princeton University, N.J. (1746), 260,000 vols.; University of California at Los Angeles (1891), 252,000 vols.; University of Pennsylvania (1749), 285,000 vols. There are numerous other college libraries, several of them even larger than some of those named above.

The establishment of proprietary or subscription libraries runs back into the first half of the 18th century, and is connected with the names of Benjamin Franklin. It was at Philadelphia, in the year 1731, that he set on foot what he called "his first project of a public nature, that of forming a subscription library. . . . The institution soon manifested its ability, was imitated by other towns and in other provinces." The Library Company of Philadelphia was soon regularly incorporated, and gradually drew to itself other collections of books, including the Loganian Library, which was vested in the company by the state legislature in 1792 in trust for public use. Hence the collection combines the character of a public and of a proprietary library, being freely open for reference purposes, while the books circulate only among the subscribing members. It numbers at present 226,000 vols., of which 11,000 belong to the Loganian Library, and may be freely lent. In 1803 Dr James Rush left a bequest of over one million dollars for the purpose of erecting a building to be called the Ridgeway branch of the library. The building is very handsome, and has been very highly spoken of as a library structure.

Philadelphia has another large proprietary library that of the Mercantile Library Company, which was established in 1821. It possesses 200,000 vols., and its members have always enjoyed direct access to the shelves. The library of the Boston Athenaeum was established in 1807, and numbers 235,000 vols. It has published an admirable dictionary-catalogue. The collection is especially rich in art and in history, and possesses a part of the library of George Washington. The Mercantile Library Association of New York, which was founded in 1820, has over 240,000 vols. New York possesses two other large proprietary libraries, one of which claims to have been formed as early as 1700 as the "public" library of New York. It was organized as the New York Society Library in 1754, and has been especially the library of the old Knickerbocker families and their descendants, its contents bearing witness to its history. It contains about 80,000 vols. The Apprentices' Library was formed about 100,000 vols., and makes a special feature of works on trades and useful arts.

The Astor Library in New York was founded by a bequest of John Jacob Astor, whose example was followed successively by his son and grandson. The library was opened to the public in 1854, and consists of a careful selection of the most valuable books upon all subjects. It is a library of reference, for which purpose it is freely open, and books are not lent out. It is a "working library for studious persons." The Lenox Library was established by James Lenox in 1870, when a body of trustees was incorporated by an act of the legislature. In addition to the funds intended for the library building and endowment, amounting to $1,247,000, the private collection of books which Mr. Lenox had long been accumulating is extremely valuable. Though it does not rank high in point of mere numbers, it is exceedingly rich in early books on America, in Bibles, in Shakespeare and in Elizabethan poetry. Both these libraries are now merged in the New York Public Library. The Peabody Institute at Baltimore was established by George Peabody in 1857, and contains a reference library open to all comers. The institute has an endowment of $1,000,000, which, however, has to support, besides the library, a conservatoire of music, an art gallery, and courses of popular lectures. It has a very fine printed dictionary catalogue and now contains nearly 200,000 vols. In the same city is the Enoch Pratt Free Library (1882) with 257,000 vols. In the city of Chicago are two very important endowed libraries, the Newberry Library (1887) with over 200,000 vols., and the John Crerar Library (1894), with 235,000 vols. Both of these are reference libraries of great value, and the John Crerar Library specializes in science, for which purpose its founder left $3,000,000.

It will be sufficient to name a few of the other endowed libraries to give an idea of the large number of donors who have given money to libraries. Silas Bronson (Waterbury), Annie T. Howard (New Orleans), Joshua Bates (Boston), Charles E. Forbes (Northampton, Mass.), Mortimer F. Reynolds (Rochester, N.Y.), Leonard Case (New York), Wm. H. S. Osterhout (Wilkes-Barre, Pa.), and all the Andrew Carnegies, whose library benefactions exceed $53,000,000. It remains to mention another group of proprietary and society libraries.

Since the organization of the government in 1789, no less than one hundred and sixty historical societies have been formed in the United States, most of which still continue to exist. Many of them have formed considerable libraries, and possess extensive collections of valuable manuscripts. Among them is the Massachusetts Historical Society, which dates from 1791. The earliest of the scientific societies, the American Philosophical Society (1743), has 93,000 vols. The most extensive collection is that of the Academy of Philadelphia, which consists of 80,000 vols. and pamphlets. For information and research the numerous professional libraries of the United States—theological, legal and medical—the reader may be referred to the authorities quoted below.

In no country has the movement for the development of municipal libraries made such progress as in the United States; these institutions called free or public as the case may be are distinguished for their work, enterprise and the liberality with which they are supported. They are established under laws passed by the different states, the first to pass such an enactment being Massachusetts, which in 1848 opened a city library containing a free public library. This was subsequently extended to the whole state in 1851. Other states followed, all with more or less variation in the provisions, till practically every state in the Union now has a body of library laws. In general the American library law is much on the same lines as the English. In most states the acts are permissive. In New Hampshire aid is granted by the state to any library for which a township contract to make a definite annual appropriation. A limit is imposed in most states on the library tax which may be levied, although there are some, like Massachusetts and New Hampshire, which fix no limit. In every American town the amount derived from the library tax usually exceeds by double or more the same rate raised in Britain in towns of similar size. For example, East Orange, N.J., with a population of 33,000, spends £2400, while Dumfries in Scotland, with 23,000 pop., spends £500. Cincinnati, 345,000 pop., expenditure £560, Kingston (London), 150,000 pop., expenditure £300, is another example. In the smaller towns the difference is not so marked, but generally the average American municipal library income is considerably in excess of the British one. Many American municipal libraries have also endowments which add to their incomes.

In one respect the American libraries differ from those of the United Kingdom. They are usually managed by a small committee or body of trustees, about five or more in number, who administer the library independent of the city council. This is akin to the practice in Scotland, although there, the committees are larger. In addition to the legislation authorizing town libraries to be established, thirty-two states have formed state library commissions. These are small bodies of three or five trained persons appointed by the different states which, acting on behalf of the state, encourage the formation of local libraries, particularly in towns and villages, and in many cases have authority to aid
their establishment by the grant out of the state funds of a certain sum (usually $100) towards the purchase of books, upon the appropriation of a similar sum by the local authorities. These commissions are prepared to aid further with select lists of desirable books, and with suggestions or advice in the problems of construction and maintenance. Such commissions are in existence in Alabama, California, Colorado, Connecticut, Delaware, Georgia, Idaho, Illinois, Indiana, Iowa, Kansas, Maine, Maryland, Massachusetts, Michigan, Minnesota, Missouri, Nebraska, New Hampshire, New Jersey, New York, North Carolina, North Dakota, Ohio, Oregon, Pennsylvania, Tennessee, Texas, Utah, Vermont, Washington and Wisconsin.

The reports and other documents issued by some of these commissioners are very interesting and valuable, especially as regards the light they throw on the working of the travelling libraries in country districts. These to some extent are a revival of the “Itinerating library” idea of Samuel Brown of Haddington in Scotland, who from 1817 to 1826 carried on a system of travelling subscription libraries in that country. At the time of his death there were 3850 in 47 libraries. The American travelling libraries, often under state-supervision, are well organized and numerous, and the books are circulated free. New York was the pioneer in this movement which now extends to most of the states which have established library commissions. There are also towns travelling libraries and deposit stations in addition to branches, so that every effort is made to bring people in outlying districts into touch with books.

The municipal libraries of the United States work in conjunction with the schools, and it is generally considered that they are part of the educational machinery of the country. In the case of New York the state libraries have been put under the control of the university of the state of New York, which also inaugurated the travelling libraries. Work with the schools and children generally is more cultivated in the libraries of the United States than elsewhere. In some cases the libraries send collections of books to the schools; in others provision is made for children’s reading-rooms and lending departments at the library buildings. At Cleveland (Ohio), Pittsburgh (Pa.), New York and many other places, elaborate arrangements are in force for the convenience and amusement of children. There is a special school, the Carnegie Library training school for children’s librarians, at Pittsburgh, and within recent years the instruction has included the art of telling stories to children at the libraries. This “story-hour” idea has been the cause of considerable discussion in the United States, librarians and teachers being divided in opinion as to the value of the service.

The chief factors in children’s work in American libraries, often overlooked by critics, are the number of non-English reading adults and the large number of children of foreign origin. The adults do not use the libraries to any large extent, but the children, who learn English at the schools, are brought into close touch with the juvenile departments of the libraries. In this way many libraries are obliged to undertake special work for children, and as a rule it is performed in a sane, practical and economical manner. The preponderance of women librarians and their natural sentimental regard for children has tended to make this work loom rather largely in some quarters, but with these exceptions the activity on behalf of children is justified on many grounds. But above all, it is manifest that a rapidly growing nation, finding homes for thousands of foreigners and their children annually, must use every means of rapidly educating their new citizens, and the public library is one of the most efficient, and ready ways of accomplishing this great national object.

With regard to methods, the American libraries are working on much the same plan as those of the United Kingdom. They allow access to the shelves more universally, and there is much more standardization in classification and other internal matters. The provision of books is more profuse, although there is, on the whole, more reading done in the United Kingdom. The largest municipal library system in America, and also in the world, is that of New York City, which, after struggling with a series of Free Circulating Libraries, blossomed out in 1895 into the series of combinations which resulted in the present great establishment. In that year, the Astor and Lenox libraries (see above) were taken over by the city, and in addition, $2,000,000 was given by one of the heirs of Mr. S. J. Tilden, who had bequeathed about $4,000,000 for library purposes in New York but whose will had been upset in the law courts. In 1901 Mr Andrew Carnegie gave about £1,500,000 for the purpose of providing 65 branches, and these are now nearly all erected. A very fine central library building has been erected, and when the organization is completed there will be no system of municipal libraries to equal that of New York. It possesses about 1,400,000 vols. in the consolidated libraries. Brooklyn, although forming part of Greater New York, has an independent library system, and possesses about 360,000 vols. distributed among 26 branches and including the old Brooklyn and Manhattan which has been absorbed in the municipal library system. At Boston (Mass.) is one of the most renowned public libraries in the United States, and also the oldest established by act of legislature. It was first opened to the public in 1834, and is now housed in a very magnificently decorated building which was completed in 1895. The central library contains many fine special collections, and there are 28 branch and numerous school libraries in connexion. It possesses about 1,000,000 vols. altogether, its annual circulation is about 1,500,000 vols., and its annual expenditure is nearly $750,000.

Other notable municipal libraries are those of Philadelphia (1891), Chicago (1872); Los Angeles (Cal.), 1872; Indianapolis (1868), Detroit (1865), Minneapolis (1885), St. Louis (1865), Newark (1889), Cincinnati (1856), Cleveland (1869), Allegheny (1890), Pittsburgh (1895), Providence, R.I. (1875), Milwaukee (1875), Washington, D.C. (1888), Worcester, Mass. (1895), Buffalo (1872). One of this series—Philadelphia—contains a select list of libraries in the United States; Arthur E. Bostwick, The American Public Library, illus. (New York, 1910)—the most comprehensive general book; Bureau of Education, Statistics of Public Libraries in the United States and Canada (1893) has been succeeded by a list of “Public, Society and School Libraries,” reprinted at irregular intervals from the Report of the Commissioner of Education and giving a list of libraries containing over 5000 vols. with various other particulars; Clegg, International Directory of Booksellers (1910) and earlier issues—contains a list of American libraries with brief particulars; John C. Dana, A Library Primer (Chicago, 1870)—the standard manual of American library practical instruction; the Directory of the New York Public Library (6th ed., Minneapolis, 1908)—a brief list of 4500 libraries, with indication of the annual income of each; Wm. I. Fletcher, Public Libraries in America (2nd ed., Boston, 1899), illus.; T. W. Koch, Portfolio of American Libraries (New York, 1886); Small Library Buildings (Boston, 1908); A. R. Spofford, A Book for all Readers, the Formation of Public and Private Libraries (1905).

France.

French libraries (other than those in private hands) belong either to the state, to the departments, to the communes or to learned societies, educational establishments and other public institutions; the libraries of judicial or administrative bodies are not considered to be owned by them, but to be state property. Besides the unrivalled library accommodation of the capital, France possesses a remarkable assemblage of provincial libraries. The communal and school libraries also form striking features of the French free library system. Taking as a basis for comparison the Tableau statistique des bibliothèques publiques (1857), there were at that date 340 departmental libraries with a total of 3,734,260 vols., and 44,436 MSS. In 1908 the number of volumes in all the public libraries; communal, university, learned societies, educational and departmental, was more than 20,600,148 vols., 93,083 ed., 8 and 3,519,750 MSS. Paris now possesses over 10,770,000 printed vols., 147,543 MSS., 5000 incunabula, 600,439 maps and plans, 2,000,000 (designs and reproductions).

The Bibliothèque Nationale (one of the most extensive libraries in the world) has had an advantage over others in the length of time during which its contents have been accumulating, and in the great zeal shown for it by several kings and other eminent men. Enthusiastic writers find the
original of this library in the MS. collections of Charlemagne and Charles the Bald, but these were dispersed in course of time, and the precious relics of them which the national libraries now possess have been acquired at a much later date. Of the library which St Louis formed in the 13th century (in imitation of what he had seen in the East) nothing has fallen into the possession of the Bibliothèque Nationale, but much has remained of the royal collections made by kings of the later dynasties. The real foundation of the institution (formerly known as the Bibliothèque du Roi) may be said to date from the reign of King John, the Black Prince’s captive, who had a considerable taste for books, and bequeathed his “royal library” of MSS. to his successor Charles V. Charles V. organized his library in a very effective manner, removing it from the Palais de la Cité to the Louvre, where it was arranged on desks in a large hall of three storeys, and placed under the management of the first librarian and cataloguier, Claude Mallet, the king’s valet-de-chambre. His catalogue was a mere shelf-list, entitled Inventaire des Lires du Roy nostre Seigneur estans au chasteau du Louvre; it is still extant, as well as the further inventories made by Jean Blanchet in 1535, and by Jean Le Bègue in 1417 and 1424. Charles V. was very liberal in his patronage of literature, and many of the early monuments of the French language are due to his having employed Nicholas Oresme, Raoul de Presle and other scholars to make translations from ancient texts. Charles VI. added some hundreds of MSS. to the royal library, which, however, was sold to the regent, duke of Bedford, after a valuation had been established by the inventory of 1424. The regent transferred it to England, and it was finally dispersed at his death in 1435. Charles VII. and Louis XI. did little to repair the loss of the precious Louvre library, but the news of the invention of printing served as a stimulus to the creation of another one, of which the first librarian was Laurent Paulmier. The famous miniaturist, Jean Fouquet of Tours, was named the king’s enlumineur, and although Louis XI. neglected to avail himself of many precious opportunities that occurred in his reign, still the new library developed gradually under the help of Jean Le Bègue. Charles VIII. enriched it with many fine MSS. executed by his order, and also with most of the books that had formed the library of the kings of Aragon, seized by him at Naples. Louis XII., on coming to the throne, incorporated the Bibliothèque du Roi with the fine Orleans library at Blois, which he had inherited. The Blois library, thus augmented, and further enriched by plunder from the palaces of Pavia, and by the purchase of the famous Gruthuyse collection, was described at the time as one of the four marvels of France. Francis I. removed it to Fontainebleau in 1535, enlarged by the addition of his private library. He was the first to set the fashion of fine artistic bindings, which was still more cultivated by Henry II., and which has never died out in France. During the librarianship of Amyot (the translator of Plutarch) the library was transferred from Fontainebleau to Paris, not without the loss of several books seized by poaching thieves. Without IV. removed it to the Collège de Clermont. But in 1604 another change was made, and in 1622 it was installed in the Rue de la Harpe. Under the librarianship of J. A. de Thou it acquired the library of Catherine de Medici, and the glorious Bible of Charles the Bald. In 1677 a decree was passed that two copies of every new publication should be deposited in the library, but this was not rigidly enforced till Louis XIV.’s reign. The first catalogue worthy of the name was finished in 1702, and contains a description of some 6000 vols., chiefly MSS. Many additions were made during Louis XIII.’s reign, notably that of the Dupuy collection, but a new era dawned for the Bibliothèque du Roi under the patronage of Louis XIV. The enlightened activity of Colbert, one of the greatest of collectors, so enriched the library that it became necessary for want of space to make another removal. It was therefore in 1660 installed in the Rue Vivien (now Vivienne) not far from its present habitat. The departments of engravings and medals were now created, and a long line rose to nearly equal importance with that of books. Marolles’ prints, Fourquet’s books, and many from the Mazarin library were added to the collection, and, in short, the Bibliothèque du Roi had its future pre-eminence undoubtedly secured. Nic. Clémence made a catalogue of 1684 according to an arrangement which has been followed ever since (that is, in twenty-three classes, each one designated by a letter of the alphabet), with an alphabetical index to it. After Colbert’s death Louvois emulated his predecessor’s labours, and employed Mabillon, Thevenot and others to procure fresh accessions from all parts of the world. A new catalogue was compiled in 1688 in 8 vols. by several distinguished scholars. The Abbé Louvois, the minister’s son, became head of the library in 1691, and opened it to all students—a privilege which although still withdrawn was afterwards restored. Towards the end of Louis XIV.’s reign it contained over 70,000 vols. Under the management of the Abbé Bignon numerous additions were made in all departments, and the library was removed to its present home in the Rue Richelieu. Among the more important acquisitions were 6000 MSS. from the private library of the Colbert family, Bishop Huet’s forfeited collection, and a large number of Oriental books imported by missionaries from the farther East, and by special agents from the Levant. Between 1739 and 1755 a catalogue of 1911 vols. was printed, which enabled the administration to discover and to sell all the MSS. of the library. The last reign saw the sale of the La Vallière library furnished a valuable increase both in MSS. and printed books. A few years before the Revolution broke out the latter department contained over 300,000 vols. and opuscules. The Revolution was serviceable to the library, now called the Bibliothèque Nationale, by increasing it with the forfeited collections of the émigrés, as well as of the suppressed religious communities. In the midst of the difficulties of placing and cataloguing these numerous acquisitions, the name of Van Praet appears as an administrator of the first order. Napoleon increased the amount of the government grant; and by the strict enforcement of the law concerning new publications, as well as by the acquisition of several special collections, the Bibliothèque made considerable progress during his reign towards realizing its idea that it should be universal in character. At the beginning of last century the recorded numbers were 35,000 printed vols., 83,000 MSS., and 1,500,000 engravings. After Napoleon’s downfall the MSS. were transferred from Berlin, Hanover, Florence, Venice, Rome, the Hague and other places had to be returned to their proper owners. The MacCarthy sale in 1817 brought a rich store of MSS. and incunabula. From that time onwards to the present, under the enlightened administration of MM. Taschereau and Delisle and Marcel, the collections have been very extensive.

According to the statistics for 1908 the riches of the Bibliothèque Nationale may be enumerated as follows: 1) Département des Imprimés: more than 3,000,000 vols.; Maps and plans, 500,000 in the Département des estampes; the Département des manuscrits and the Département des estampes are divided into the MSS. and the printed books; 2) Département des Manuscrits: more than 3,000,000 vols.; 3) Département des Estampes: more than 2,000,000 vols.; 4) Département des Photographies: 400,000 vols.; 5) Département des Anciens dépots: more than 200,000 vols.; 6) Département de l’Inventaire: more than 600,000 vols.; 7) Département de la Révolution: more than 200,000 vols.; 8) Département des Études: 1,000,000 vols. The administration of the "salle de travail," is obtained through a card procured from the secretariat office; the "salle publique" contains 344 places for readers, who are able to consult more than 50,000 vols. of books of reference. Great improvements have lately been introduced, and the library is divided into separations, or parts, for the use of the various classes of readers and is much used. New buildings are in process of construction. The slip catalogue index in volumes dated from 1882 and gives a list of all acquisitions since that date; it is divided into two parts, one for the new acquisitions, and another for the old. There is not yet, as at the British Museum, an alphabetical catalogue of all the printed works and kept up by periodical supplements, but since 1897 a Catalogue général des livres imprimés has been begun. In 1907, 1500 vols. of printed books were added to the catalogue, and some volumes are published each year, but the earlier volumes only contain a selection of the books; this inconvenience has now been remedied. Among the other catalogues published by the Printed Book Department, may be noted: Répertoire alphabétique des livres mis à la disposition des lecteurs dans la salle de travail (1896, 8 vols.), Listes des périodiques français et étrangers mis à la disposition des lecteurs (1907, 40 vols.), Liste des périodiques étrangers, (new ed., 1896, 8 vols.) and Supplement (1902, 8 vols.), Bulletin des dissertations et écrits académiques provenant des universités universitaires (from 1882, 8 vols.). The other extensive catalogues apart from those of the 19th century are: Catalogue de l’Histoire de France (1895–1899, 40, 11 vols.); Table des auteurs,
comte d'Artois, who had bought it from the marquis de Paulmy in his lifetime. It contains at the present time about 600,000 vol., 10,000 manuscripts, 20,000 prints, and the Bastille collection (2500 portfolios) of which the inventory is complete; it is the richest library for the literary history of France and has more than 30,000 theatrical pieces.

L’inventaire des manuscrits was made by H. Martin (1885-1899, t. i.-vii.); the other catalogues and lists are: *Extrait du catalogue des journaux consignés à la bibliothèque de l’Arsenal* ("Bulletin des bibliothèques de l'arsenal", t. i.); *Armes des manuscrits* (1892-1894, 3 vols., 8vo); *Notice sur les dépôts littéraires* par J. Labiche (1880, 8vo); *Catalogue des estampes, dessins et cartes* (1899, 4 vols., 8vo); *Inventaire sommaire des estampes de la bibliothèque de l’Arsenal* (1890, 2 pts., 8vo).

The Bibliothèque Mazarine owes its origin to the great cardinal, who decided the direction to Gabriel Naudé; it was open to the public in 1642, and was transferred to Rue de Richelieu in 1648. Dispersed during the Fronde in the lifetime of Mazarin, it was reconstituted after the death of the cardinal in 1661; when it contained 40,000 vols., which were left to the Collège des Quatre-Nations, which in 1691 made it again public. It now has 250,000 vols.; with excellent manuscript catalogues.

The catalogues of incunabula and manuscripts were printed: P. Marchal, *Les dépôts publics de la bibliothèque Mazarine* (1893, 8vo); *Supplément, additions et corrections* (1898, 4 vols., 8vo); *Catalogue des MSS*, par A. Mounin (1885-1892, 4 vols., 8vo); *Inventaire sommaire des MSS. grecs*. P. H. Maclear.

The first library of the Genoese had nearly disappeared owing to bad administration when Cardinal François de la Rochefoucauld, who had charge of the reformation of that religious order, constituted in 1642 a new library with his own books. The Bibliothèque Ste-Geneviève in 1716 possessed 45,000 vols.; important gifts were made by Letellier in 1791, and the duc d’Orléans increased it still more. It became national property in 1791, and was called the Bibliothèque du Panthéon and added to the Légy Henry IV. under the empire. In 1808 the library contained 350,000 printed vols., 1225 incunabula, 3550 manuscripts, 10,000 prints (including 7357 portraits and 1410 engravings).

The printed catalogues at present comprise: Poirée and Lamoureux, *Catalogue abrégé de la bibliothèque Ste-Geneviève* (1801, 8vo); 3 supplements (1809-1896, 1897-1899, 1900-1902); *Catalogue des incunables de la bibliothèque Ste-Geneviève*, rédigé par Daunou, published by M. Pellechet (1892, 8vo); *Catalogue général des MSS. de Ch. Kohler* (1894-1896, 2 vols., 8vo); *Inventaire sommaire des MSS. grecs*, par H. Omont; *Notice sur quelques MSS. normands*, par E. Deville (1904-1906, 10 pts., 8vo).

The Bibliothèque des Archives nationales, founded in 1688 by Daunou, contains 300,000 vols., on sciences auxiliary to history, is also accessible to the officials.

It would be impossible to describe all the official, municipal and academic libraries of Paris or less open to the public, which are about 200 in number, and in the following survey we deal only with those having 10,000 vols., and over.

The Bibliothèque du Ministère des affaires étrangères was founded by the marquis de Torcy, minister for foreign affairs under Louis XIV.; it contains 80,000 vols., and is for official use only. The Bibliothèque du Ministère de l'Agriculture dates from 1882 and has 10,000 vols.; it contains a library of (10,000 vols.) dates from 1807; the catalogue was published in 1905; the library of the Colonial office is attached to this ministry; suppressed in 1896, it was re-established in 1899, and now contains 6000 vols.; it is open to the officials and the public.

There are 30,000 vols. in the Bibliothèque du Ministère du commerce et de l'industrie; the Bibliothèque du Ministère des finances was burnt at the Commune, but has been reconstituted and now contains 30,000 vols.; it contains the libraries of the following offices: Contributions directes, Contributions indirectes, Enregistrement et inspection des finances; the contents of these four libraries make a total of 13,500 vols. The Bibliothèque du Ministère de l'Intérieur, containing 100,000 vols. and 800 MSS., and an income of 20,000 francs; the catalogues are Bibliothèque du dépôt de la guerre: *Catalogue* (1883-1890); *Suppléments* (1893-1896); *Catalogue des MSS. par J. Lemoine* (1899, 2 vols., 8vo). In the Comité de santé (10,000 vols.), École supérieure de guerre (70,000 vols.), Comité technique de l’artillerie (20,000 vols.). The Bibliothèque du Ministère de l’Intérieur was founded in 1793 and has 80,000 vols. The Bibliothèque du Ministère de la Justice possesses 10,000 vols., and L’imprimerie Nationale which is connected with it has a further 19,000 vols. There are also the following law libraries:
Cour d'appel (12,000 vols.); Ordre des avocats, dating from 1821 (56,000 vols., with a catalogue printed in 1880—1882); the Bibliothèque des avocats de la cour de Cassation (20,000 vols.); that of the Cour de Cassation (40,000 vols.). The Bibliothèque du Ministère de la Marine has 65,000 vols. and 250 MSS. The Ministère des Travaux publics has 65,000 vols., the Bibliothèque de l'Expédition de Catalogne et téléglyphes a further 30,000 vols. The Bibliothèque de la Chambre des députés (1795) possesses 250,000 printed books and 1546 MSS. (Catalogue des manuscrits, by E. Ceycouse and H. Debray, 1907; Catalogue des livres de jurisprudence, d'économie politique, d'histoire, de philosophie, et d'administration, 1883). The Bibliothèque du Sénat (1818) contains 150,000 vols. and 1343 MSS. The Bibliothèque du Conseil d'État has 30,000 vols. All these libraries are only accessible to officers of the State by special permission.

The Bibliothèque Historique de la ville de Paris was destroyed in 1871, but Jules Cousin reconstituted it in 1872; it possesses 400,000 vols., 3500 MSS. and 14,000 prints; the principal printed catalogues are Catalogue des manuscrits, by E. Boursein (1893); a bulletin has been issued periodically since 1906. The Bibliothèque administrative de la préfecture de la Seine is divided into two sections: French (30,000 vols.) and foreign (22,000 vols.); it is only accessible to officials, to persons having a card of introduction; the catalogues are printed.

The other libraries connected with the city of Paris are that of the Conseil municipal (20,000 vols.), the Bibliothèques Municipales de Paris, which with a third set of the collections of the Bibliothèque du Prytanée, in 1808 Bibliothèque des Quatre Lycées and in 1812 Bibliothèque de l'Université de France. The sections into which the Bibliothèque de l'Université is now divided are: (1) Facultés de Sciences et des Lettres à la Sorbonne, (2) Faculté de Médecine, (3) Faculté de Droit, (4) Faculté des Sciences économiques et statistiques. The separation of Church and State there was a fifth section, that of Protestant theology. After the Bibliothèque nationale it is the richest in special collections, and above all in regards classical philology, and also the earliest. The principal additions since the death of M. de Chateaubriand, its establishment in 1897 in the buildings of the old Sorbonne, have made it a library of the very first rank. The reading-room only seats about 300 persons. The average attendance of these rooms is 3000 persons. The library is open from 2 to 8 p.m. The collections are enormous, the annual addition of vellum and paper books is about 1500 to 3000 vols. a day, and the loans amount to 14,000 vols. per year. The store-rooms, although they contain more than 1200 metres of shelves and comprise two buildings of five storeys each, are insufficient for the annual additions of 550,000 vols., 2800 periodicals which include over 70,000 vols., 320 incunabula, 2106 MSS., more than 2000 maps and plans and prints. The alphabetical catalogues are kept up day by day on slips which are connected from time to time. The catalogue of paintings in 1812 was already 150,000; of engravings, some had already been published: Périodiques (1905); Cartulaires (1907); Mégagnes juridiques et publications communautaires (1908); Inventaires des MSS., by E. Chatelain (1825); Incunabula et incunables, by one of the chief librarians (1824); Catalogue de la Bibliothèque 1701-1550, by Ch. Beaulieu (1906); Nouvelles acquisitions (1905-1906); Catalogue des livres de G. Duplessis donnés à l'Université de Paris (1897). Catalogue collectif des bibliothèques universitaires de France (1825). Since 1878 the library possesses a rich collection, the catalogues are as follows: M. L. Cottini, Catalogue des objets de la Bibliothèque de la Faculté de Droit et Sciences économiques (1905-1906); A. Maire, Répertoire des thèses de Lettres (1800-1905); A. Maire, Catalogue des manuscrits de la Bibliothèque de la Faculté de Droit et Sciences économiques (1800-1901); A. Maire, Catalogue des inscriptions et des manuscrits de la Bibliothèque de l'Institution des Estivans; Catalogue des thèses publiés par le Ministère de l'Instruction publique (1882; &c.).

At the Sorbonne are also to be found the libraries of J. A. Dumont and V. C. H. de Chauliac, and of the laboratories, of which the richest is the geological (50,000 specimens and books). The section relating to medicine, housed since 1891 in the new buildings of the Faculté de Médecine, includes 180,000 vols. and 88 MSS. (catalogue 1910). The Bibliothèque de la faculté de droit dates from 1772 and contains 80,000 vols., 239 MSS. The fourth section, l'Ecole supérieure de pharmacie, greatly developed since 1882, now contains 50,000 vols.

The other libraries connected with higher education include that of the Bibliothèque de l'Institut de France (10,000 vols., 100,000 prints, 14,000 drawings). The library of the Ecole normale supérieure (1794), established in the Rue d'Ulm in 1846, has received legacies from Verdet (1867), Cabocho (1877), Lernamwhitcomb (1909), and is now attached to the École des Sciences et des Lettres (1871); it is practically the same as that of the Sorbonne, being devised by Philippe Lebas (librarian of the Sorbonne) about 1845; there are 200,000 vols. The library of the Musée d'histoire naturelle dates from 1821, and the Collège de France, erected in 1530, contains 8000 vols., and original drawings on vellum beginning in 1631. The Bibliothèque de l'Office et Musée de l'Instruction publique (formerly Musée pédagogique), founded only in 1880, has 75,000 vols. In 1766 was established the Bibliothèque de l'Institut de France, which is very rich; its acquisitions come particularly from gifts and exchanges (400,000 vols., numerous and scarce; valuable MSS., especially modern ones).

The following may be briefly mentioned: Conservatoire national de musique (1755), which receives 816 MSS. published in France relating to music (200,000 vols.); the Bibliothèque du théâtre de l'Opéra (25,000 vols., 5000 songs, 20,000 romances, and a dramatic library of 12,000 vols. and 20,000 prints); the Théâtre français (6800 vols.); the Bibliothèque de l'Institut de France, which is very rich; its acquisitions come particularly from gifts and exchanges (400,000 vols., numerous and scarce; valuable MSS., especially modern ones).

The libraries of the university and the institutions dealing with higher education in Paris are well organized and their catalogues generally printed.

The Bibliotheque de l'Université, although at present grouped as a system in four sections in different places, historically considered is the library of the Sorbonne. This was founded in 1762 by Montesquieu and only included the faculties of Arts and Theology. Itrahmly consisted of 10,000 vols., and was reconstituted in 1821 by the Bibliothèque du Pays de la Seine and the Bibliothèque de Paris, in the Conservatoire du Cinéma (10,000 vols., 22 Hospitals (62,887 vols.), the Préfecture de police (10,000 vols.), the Bibliothèque Forney (10,000 vols. and 80,000 prints), the five Écoles hypothécaires supérieures (16,000 vols.), the six professional schools in Paris.

The libraries of the University and the institutions dealing with higher education in Paris are well organized and their catalogues generally printed.

Before the Revolution there were in Paris alone 1100 libraries containing altogether 2,000,000 vols. After the suppression of the religious orders the libraries were confiscated, and in 1791 more than 500,000 vols. were seized in 162 religious houses and transferred locally. The sequestration took place with a decree of November 14, 1798. In the provinces 6,000,000 vols. were seized and transferred to local depositories. The organizations of the central libraries under the decree of 3 Brumaire in 1793 (October 25, 1795) came to nothing, but the consular edict of January 28, 1803 gave definitive organization to the books in the local depositories. From that time the library system was reconstituted, alike in Paris and the provinces. Unfortunately many precious books and MSS. were burnt, since by the decree of 3 Brumaire in 1793 (October 25, 1795) the Committee of Instruction ordered, on the proposition of its president the deputy Romme, the destruction or modification of books and objects of art, under the pretext that they recalled the outward signs of feudalism.

The books in the provincial libraries, not including those in private hands or belonging to societies, number over 9,200,000 vols., 15,540 incunabula and 93,986 MSS. The number in the colonies and protected states outside France is uncertain, but it extends to more than 200,000 vols.; to this number must be
added the 2,428,954 vols. contained in the university libraries. There are over 300 departmental libraries, and as many belong to learned societies. The number of the provincial libraries is lower than that of the Parisian collections. With the exception of 26 libraries connected specially with the state, the others are municipal and are administered under state control by municipal librarians. The original foundation of most of the libraries dates but a short time before the Revolution, but there are a few exceptions. Thus the Bibliothèque d'Angers owes its first collection to Alain de la Rue about 1376; it now contains 72,485 vols., 134 incunabula and 2039 MSS. That of Bourges dates from 1466 (36,856 vols., 325 incunabula, 741 MSS.). The library of Carpentras was established by Michel Angeli between 1452 and 1474 (50,000 vols., 2154 MSS.). Mathieu de la Porte is said to be the founder of the library at Clermont-Ferrand at the end of the 15th century; it contained rather more than 40,000 vols. at the time of its union with the Bibliothèque Universitaire.

Among the libraries of the 16th century must be mentioned that at Lyons founded by François I. in 1527; it possesses 113,168 vols., 870 incunabula and 5243 MSS. That of the Palais des Arts has 82,079 vols., 64 incunabula and 311 MSS.

The most important early libraries are the following: Abbeville, by Charles Sanson in 1685 (46,929 vols., 42 incunabula, 342 MSS.); Besançon by Abché Boisot in 1699 (93,580 vols., 1000 incunabula, 2247 MSS.). In 1654 the Consistoire réformé de la République, a religious library, was established. By 1709 there were 58,900 vols., 14 incunabula, 1715 MSS. St Etienne, founded by Cardinal de Villeroi, has 50,000 vols., 8 incunabula, 343 MSS.

The principal libraries founded during the 18th century are the following: en-Provençal, established by Tournon and Méjane in 1705 (160,000 vols., 300 incunabula, 1353 MSS.); Bordeaux (200,000 vols., 1491 MSS.); Chambéry, 1736 (64,200 vols., 47 incunabula, 135 MSS.); Dijon, 1701, founded by P. Fevert (125,000 vols., 68 incunabula, 1250 MSS.); Besançon, 1726 (266,772 vols., 635 incunabula, 2485 MSS.); Marseille, 1744 (111,674 vols., 14 incunabula, 1691 MSS.); Nancy, founded in 1750 by Stanislas (126,149 vols., 205 incunabula, 1695 MSS.); Nantes, 1755 (103,328 vols., 67 incunabula, 972 MSS.); Perpignan, in 1769, founded by Abbé Massa (55,000 vols., 300 incunabula, 150 MSS.); Nîmes, founded in 1789 (110,000 vols., 602 incunabula, 1095 flos); Toulouse, by archbishop of Brienne in 1792 (213,000 vols., 896 incunabula, 1020 MSS.).

The French municipal libraries date from the Revolution, or rather from the period of the administrative law of the 18th century. The following municipal libraries possess more than 100,000 vols.: Avignon (135,000 vols., 658 incunabula, 4152 MSS.), of which the first collection is attributed to Calvet in 1610; Caen (122,000 vols., 100 incunabula, 665 MSS.); Montpellier (20,000 vols., 251 MSS.); Rouen (140,000 vols., 400 incunabula, 4000 MSS.); Tours (123,000 vols., 451 incunabula, 1699 MSS.); Versailles (101,000 vols., 251 MSS.).

The following towns have libraries with more than 50,000 volumes: Amiens, Auxerre, Beaune, Brest, Douai, L'Haÿr, Lille, le Mans, Orléans, Pau, Poitiers, Toulon and Verdun.

The catalogues of the greater part of the municipal libraries are printed. Especially valuable is the Catalogue des MSS. des bibliothèques de Paris des Départements, which began to appear in 1885; the MSS. of Paris fill 108 octavo volumes, and those of the provinces 50 volumes.

The libraries of the provincial universities, thanks to their reorganization in 1882 and to the care exercised by the general inspectors, are greatly augmented. Aix has 74,658 vols.; Alger 160,489; Besançon 24,275; Bordeaux 216,276; Caen 127,542; Clermont 175,720; Dijon 131,362; Lyon 425,624; Marseilles 53,763; Montpellier 216,038; Nancy 139,036; Poitiers 180,000; Rennes 166,427; Toulouse 232,000.

Since 1882 the educational libraries have largely developed; in 1907 there were 712 municipal libraries, containing 7,757,917 vols. The purely scholastic libraries have increased; in 1902 there were 2674 libraries with 1,034,132 vols., whilst after the reorganization (Circular of March 14, 1904) there were 3,125 libraries with 2,700,000 vols. J.P. Franklin, a pioneer for the propagation of the bibliothèques populaires and municipal libraries, has set up among the libraries which it controls, 55,185 vols., between the years 1900 and 1909.

A. France.—Information has been given for this account by M. Albert Maire, librarian at the Sorbonne. See also the following works: Bibliothèque Nationale: I. Bâtiments, collections, organisation, départements des estampes, départements des médailles et antiquités, par Henri Marcel, Henri Bouchot and Ernest Babelon. II. Le Département des imprimés et la section de géographie. Le Département des manuscrits, par Paul Marchal and Camille Courier (Paris, 1907, 2 vols.); Félix Chambon, Notes sur la bibliothèque de l'Université de Paris de 1763 à 1905 (Granat, 1905); Bosseuyck, La Bibliothèque des hôpitaux de Paris (Revue des bibliothèques, t. 18, 1908); Alfred Franklin, Guide des savants, des littérateurs et des artistes dans les bibliothèques de Paris (Paris, 1908); Instruction du 7 Mars 1869, sur l'organisation des bibliothèques militaires (Paris, 1899); Henri Jadart, Les Anciennes bibliothèques de Reims, leur sort en 1790-1791 et la formation de la bibliothèque publique (Reims, 1901); Henry Martin, Histoire des bibliothèques publiques de la ville de Paris (Paris, 1902); L. V. Pechère, Histoire des bibliothèques publiques du département de l'Aisne existant à Soissons, Laon et Saint-Quentin (Soissons, 1884); M. G. and E. Beaurepaire, Une visite à la bibliothèque de la ville de Paris (Paris, 1907); E. Stein-Altendorff, Bibliothèques municipales de la ville de Paris (Paris, 1896); B. Subercase, Les Bibliothèques populaires, scolaires et pédagogiques (Paris, 1892).

Germany (with Austria-Hungary and Switzerland).

Germany is emphatically the home of large libraries; her former wish of political unity and consequent multiplicity of capitals have had the effect of giving her many large state libraries, and the number of her universities has tended to multiply considerable collections; 161 libraries were registered by P. Schwenke in 1801. As to the conditions, hours of opening, &c., of 200 of the most important of them, there is a yearly statement in the Jahrbuch der deutschen Bibliotheken, published by the Verein deutscher Bibliothekare.

The public libraries of the German empire are of four distinct types: state libraries, university libraries, town libraries and popular libraries. The administration and financial affairs of the state and university libraries are under state control. The earlier distinction between these two classes has become less and less marked. Thus the university libraries are no longer restricted to students and professors and students, but they are widely used by scientific workers, students, and generally borrowed, especially in Prussia. In Prussia, as a link between the state and the private libraries, there has been since 1907 a special office which deals with library matters at the Ministry of Public Instruction. Generally the state does not concern itself with the town libraries and the popular libraries, but there is much in common between these two classes. Sometimes popular libraries are under the supervision of a scientifically administered town library as in Berlin, Dantzí, &c.; elsewhere, as at Magdeburg, we see an ancient foundation take up the obligations of a public library. Only in Prussia and Bavaria are regulations in force as to the professional education of librarians. Since 1904 the librarians of the Prussian state public libraries have been obliged to complete their university courses and take up their doctorate, after which they have to work two years in a library as volunteers and then undergo a technical examination. The secretarial officials since 1909 reach a certain educational standard and must pass an examination. This result has been in force as regards librarians in Bavaria from 1905.

Berlin is well supplied with libraries, 268 being registered by P. Schwenke and A. Hartzschansky in 1906, with about 5,000,000 printed vols. The largest of these is the Royal Library, which was founded by the "Great Elector" Frederick William, and opened as a public library in a wing of the electoral palace in 1696. For an extraordinary amount of every book published within the royal territories, and it has received many valuable accessions by purchase and otherwise. It now includes 1,936,000 printed vols. and over 30,000 MSS. The amount yearly expended on it is 115,500. The library is open gratis. The catalogues are in manuscript, and include two general alphabetical catalogues, the one in volumes, the other on slips, as well as a systematic catalogue in volumes. The following is an extract from the brief catalogue: "The following are the titles of the catalogues of the Royal Library of the Königliche Bibliothek in Berlin. These catalogues are kept within the library and are open gratis to all users."

Germany. Library.
The catalogue of MSS. are mostly in print, vols. 1-13, 16-23 (1853-1895). The library is specially rich in oriental MSS., chiefly due to purchases of private collections. The musical MSS. are very remarkable and form the richest collection in the world as regards them. Besides the building itself, the library consists of the Gesellschaft der bayerischen Akademie der Wissenschaften, which has long been too small, and a new one was completed in 1909. The building occupies the whole space between the four streets: Unter den Linden, Dorotheenstrasse, Universitatsstrasse and the Altes Museum. They hold everything from the University Library and the Academy of Sciences. The conditions as to the use of the collections are, as in most German libraries, very liberal. Any adult is allowed to have books in the reading-rooms. This library has a specimen catalogue, and a part of a catalogue for the library's own use. Collections of MSS., if especially valuable, may be deposited in some public library where he conveniently use them. In 1908-1909 264,000 vols. were used in the reading-rooms, 312,000 were lent inside Berlin, and 32,000 outside. There is a regular and extensive exhibition of MSS., prints and other Library and a great number of Prussian libraries. It is the source in Bavaria, Württemberg and Baden; the oldest is that between Darmstadt and Giessen (dating from 1837). There is either no charge for borrow to the borrower or the cost is very small. The reading-rooms are open during the week from 9 to 9, and holidays, open daily from 9 to 9, the borrowing counter from 9 to 6.

Associated with the Royal Library are the following undertakings: the Gesamtkatalog der preussischen wissenschaftlichen Bibliotheken (describing the printed books in the Royal Library and the Prussian University Libraries in one general catalogue upon slips), the Auskunftsbücher der Deutschen Bibliotheken (bureau to give information of the particular library of the Commission für den Gesamtkatalog der Wiegendrucke (to draw up a complete catalogue of books printed before 1500). The University Library (1831) numbers 220,000 vols. together with 250,000 dissertations and thems may be consulted, and the Kommission für den Gesamtkatalog der Wiegendrucke (to draw up a complete catalogue of books printed before 1500). The University Library (1831) numbers 220,000 vols. together with 250,000 dissertations and numerous printed works, and 14 municipal reading-rooms. The 28 Volksbibliotheken contain (1908) 104,000 vols. The Prussian university libraries outside Berlin include Bonn (312,000 printed vols., 1500 MSS.), Göttingen, its foundation in 1737/67 the best administered library of the 18th century (552,000 printed vols., 6800 MSS.); Greifswald (200,000 printed vols., 800 MSS.); Halle (261,000 printed vols., 3700 MSS.); Königsberg (287,000 printed vols., 1500 MSS.); Marburg (315,000 printed vols., and about 800 MSS.); Münster (191,000 printed vols., 300 MSS.); Oldenburg (547,000 printed vols., 4600 MSS.); the Landesbibliothek at Cassel (230,000 printed vols., 4400 MSS.); and the Kaiser-Wilhelm-Bibliothek at Posen (163,000 printed vols.). A number of the larger towns possess excellent municipal Libraries in the provinces, Breslau (112,000 vols.), Breslau (45,000 MSS.); Cannstatt (146,000 vols., 4500 MSS.); Frankfurt a/M (342,000 vols. besides MSS.); Cassel Murhardsche Bibliothek (141,000, 700 MSS.); Cologne (175,000 vols.); Treves (100,000 vols., 2200 MSS.); Wiesbaden (48,000 vols.).

The libraries of Munich, though not so numerous as those of Berlin, include two of great importance. The Royal Library, for a long time the largest collection of books in Germany, was founded in 1505 by the Dukes of Bavaria with a princely foundation above 15,000 incunabula, many of them being derived from the libraries of 150 monasteries closed in 1803. The oriental MSS. are numerous and valuable, and include the library of Martin Haug. The amount annually issued from the Library is about 15,000 vols., and the number of the printed books are in manuscript, and include (1) a general alphabetical catalogue, (2) an alphabetical repertory of each of the 195 subdivisions of the library, (3) geographical and other subject catalogue in manuscript, a special catalogue for the new acquisitions complete; the first was published in 1858. The library is open on weekdays from 8 to 10 (November to March 8.30 to 1), and on Monday to Friday (except from August 1 to September 15). Also from 3 to 8.

The regulations for the use of the Library are very similar to those of the Royal Library.
(about 100,000 vols.) after that at Berlin. Alsace-Lorraine has the most recently formed of the great German collections—the Universität- und Landesbibliothek at Strasbourg, which was founded in 1871 to replace that which had been destroyed in the siege, already ranks amongst the largest libraries of the empire. Its books amount to 92,000 vols., the number of MSS. is 5,900.

The Adressbuch der Bibliotheken der österreich-ungarischen Monarchie by Bohatta and Holzmann (1900) describes 10,14 libraries in Austria, 6,565 in Hungary, and 2,313 in Bosnia and Herzegovina. Included in this list, however, are private lending libraries.

One of the most important collections in Europe is the Imperial Public Library at Vienna, established by Litovka (a) in 1440, although its illustrious librarian Lambechius, in the well-known inscription over the entrance to the library which summarizes his history attributes this honour to Frederick's son Maximilian. However this may be, the munificence of succeeding emperors greatly added to the wealth of the collection, including a not inconsiderable portion of the dispersed library of Corvinus. Since 1808 the library has also been entitled to the copy-right privilege in respect of all books published in the empire. The sum devoted to the purchase and binding of books is $5,000 annually. The library consists of 1,900,000 vols; 8,000 incunabula. The MSS. amount to 27,000, with 100,000 papers of the collection of Archduke Rainer. The main library apartment is one of the most splendid halls in Europe. Admission to the reading-room is free to everybody, and books are also lent out under stricter limitations. The University Library of Vienna was established by Maria Theresa. The reading-room is open to all comers, and the library is open from 1st Oct. to 30th June from 9 a.m. to 8 p.m.; in the other months for shorter hours. In 1897 447,301 vols. were used in the library, 45,000 vols. lent out in Vienna, and 6,519 vols. sent carriage free to borrowers outside Vienna. The number of printed vols. is 757,000. For the purchase of books and binding the Vienna University Library has annually 60,000 crowns from the state as well as 44,000 crowns from matriculation fees and contributions from the students.

The total number of libraries in Vienna enumerated by Holzmann is 109, and many of them are of considerable extent. One of the oldest and most important libraries of the monarchy is the University Library at Cracow, with 360,000 vols. and 1,000 MSS. This number is very considerable. They possess altogether more than 2,500,000 printed vols., 25,000 incunabula and 5,000 MSS. The oldest of them, and the oldest in Austria, is that of the monastery of St Peter at Salzburg, which was established in 1397. According to the Guttenberg MS., the number of MSS. at the time of its foundation is nearly 1,500 incunabula. The three next in point of antiquity are Kremsminster (100,000), Admont (86,000) and Melk (70,000), all of them dating from the 12th century. Many of the librarians of these libraries are trained in the great Vienna libraries.

There is no official training as in Prussia and Bavaria.

Information about income, administration, accessions, &c., of the chief libraries in the Hungarian kingdom, are given in the Hungarian Statistical Year Book annually. The largest library in Hungary is the Széchenyi-Nationalbibliothek at Budapest, founded in 1802 by the gift of the library of Count Franz Széchenyi. It contains 400,000 printed vols., 10,000 MSS., and has a remarkable collection of Hungarica. The University Library of Budapest includes 275,000 printed books and more than 200 MSS. Since 1897 there has been in Hungary a Chief Inspector of Museums and Libraries whose duty is to watch all public museums and libraries which are administered by communities, monastic libraries, and bodies and so on. He also has undertaken the task of organizing a general catalogue of all the MSS. and early printed books in Hungary.

The libraries of the monasteries and other institutions of the Catholic Church are many in number but not so numerous as in Austria. The chief among them, the library of the Benedictines at St Martin, in the market of the order in Hungary and contains nearly 170,000 vols. It was reconstituted in 1802 after the re-establishment of the order. The principal treasures of this abbey (11th century) were, on the secularization of the monasteries under Joseph II, distributed among the state libraries in Budapest.

Among the Swiss libraries, which numbered 206 in 1868, there is none of the first rank. Only three possess over 200,000 vols.—the University Library at Basle founded in 1460, the Cantonal Library at Lausanne, and the Stadtbibliothek at Berne, which since 1905 is united to the University Library of that city. One great advantage of the Swiss libraries is that they nearly all possess printed catalogues, which greatly further the plan of compiling a great general catalogue of all the libraries of the republic. A valuable co-operative work is their treatment of Helvetiana. All the literature since 1848 is collected by the Landes-Bibliothek at Berne, established in 1895 for this special object. The older literature is brought together in the Bürgerbibliothek at Lucerne, for which it has a government grant. The monastic libraries of St Gall and Einsiedeln date respectively from the years 830 and 946, and are of great historical and literary interest.

AUTHORITIES.—Information has been supplied for this account by Professor Dr A. Hortzschaus, librarian of the Royal Library, Budapest; Dr A. Lombard, editor of the Bibliothek der Universität; and P. Schwenger of the Bibliothek der Universität (Leipzig, 1893); J. Schwenke, Bibliothek der Universität (Leipzig, 1892-1910); Berliner Bibliotheksführer by P. Schwenge and A. Hortzschaus (Berlin, 1906); A. Hortzschaus, Die K. Bibliothek zu Berlin (Berlin, 1908); Ed. Zurncke, Leitbiro-Bibliotheksführer (Leipzig, 1899); J. Bohatta and M. Escher, "Bibliothekswesen in Handbuch der Schweiz Volkswirtschaft, vol. i. (1903)."

Italy.

As the former centre of civilization, Italy is, of course, the country in which the oldest existing libraries must be looked for, and in which the rarest and most valuable MSS. are preserved. The Vatican at Rome and the Laurentian Library at Florence are sufficient in themselves to entitle Italy to rank before most other states in that respect, and the venerable relics at Vercelli, Monte Cassino and La Cava bear witness to the enlightenment of the peninsula while other nations were slowly taking their place in the circle of civilized nations. The legal rights and interests which so long helped to preserve the unity of Italy were useful in creating and preserving at numerous minor centres many libraries which otherwise would probably have been lost during the progress of absorption that results from such centralization as exists in England. In spite of long centuries of suffering and of the aggression of foreign swords and foreign gold, Italy is still rich in books and MSS. The latest official statistics (1896) give particulars of 1831 libraries, of which 419 are provincial and communal. In 1893 there were 542 libraries of a popular character and including circulating libraries.

The governmental libraries (bibliothecae governativa) number 36 and are under the authority of the minister of public instruction. The Regolamento controllando them was issued in the Bollettino Ufficiale, 5 Dec. 1907. They consist of the national central libraries of Rome (Vittorio Emanuele) and Florence, of the national libraries of Milan (Brádena), Naples, Palermo, Turin and Venice (Mariani); the biblioteca governativa at Cremona; the Marcelliana, the Mediceo-Laurenziana and the Riccardiana at Florence; the governativa at Lucca; the Estense at Modena; the Brancacciana and that of San Giacomo at Naples; the Palatina at Parma; the Angelica, the Casanatense, and the Lancisiana at Rome; the university libraries of Bologna, Cagliari, Catania, Genoa, Messina, Modena, Naples, Padua, Pavia, Pisa, Rome and Sassari; the Ventimiliana at Catania (joined to the university library for administrative purposes); the Vallicelliana and the musical library of the R. Accad. of St Cecilia at Rome; the musical section of the Palatine at Parma; and the Lucchesi-Palli (added to the national library at Naples). There are provisions whereby small collections can be united to larger libraries in the same place and where there are several government libraries in one city a kind of corporate administration can be arranged. The libraries belonging to bodies concerned with higher education, to the royal scientific and literary academies, fine art galleries, museums and scholastic institutions are ruled by special regulations. The minister of public instruction is assisted by a technical board.
The librarians and subordinates are divided into (1) librarians, or keepers of MSS.; (2) sub-librarians, or sub-keepers of MSS.; (3) attendants, or book distributors; (4) ushers, &c. Those of class I constitute the "board of direction," which is presided over by the librarian, and meets from time to time to consider important measures connected with the administration of the library. Each library is to possess, alike for books and MSS., a general inventory, an accessions register, an alphabetical author-catalogue and a subject-catalogue. When they are ready, catalogues of the special collections are to be compiled, and these the government intends to print. A general catalogue of the MSS. was in 1910 being issued together with catalogues of oriental codices and incunabula. Various other small registers are provided for. The sums granted by the state for library purposes must be applied to (1) salaries and the catalogues of the MSS.; (2) maintenance and other expenses; (3) purchase of books, binding and repairs, &c. Books are chosen by the librarians. In the university libraries part of the expenditure is decided by the librarians, and part by a council formed by the professors of the different faculties. The rules (Boill. Ufficiale, Sept. 1910) forbids the loan of MSS. and books valuable, and obliges them to be sent to other countries under special circumstances.

The 36 bibliothecae governatoris annually spend about 300,000 lire in books. From the three sources of gifts, copyright and purchases, their accessions in 1908 were 142,930, being 21,122 more than the previous year. The number of readers is increasing. In 1908 there were 1,176,934, who made use of 1,650,542 vols., showing an increase of 30,456 readers and 67,579 books as contrasted with the statistics of the previous year. Two monthly publications catalogue the accessions of these libraries, dealing with copyright additions of Italian literature, the other with all foreign books.

The minister of public instruction has kept a watchful eye upon the literary treasures of the suppressed monastic bodies. In 1875 there were 1700 of these confiscated libraries, containing two millions and a half of volumes. About 650 of the collections were added to the contents of the public libraries already in existence; the remaining 1050 were handed over to the different local authorities, and served to form 371 new communal libraries, and in 1876 the number of new libraries so composed was 415.

The Biblioteca Vaticana stands in the very first rank among European libraries as regards antiquity and wealth of MSS. The Vatican. We can trace back the history of the Biblioteca Vaticana to the earliest records of the Scrinium Sedis Apostolicæ, which was enshrined in safe custody at the Lateran, and later on partly in the Turris Chartularia; but of all the things that used to be stored there, the only survival, and that is a dubious example, is the celebrated Codex Amiatinus now in the Laurentian Library at Florence. Of the new period inaugurated by Innocent III. there but remains to us the inventory made under Boniface VIII. The library shared in the removal of the Papal court to Avignon, where the collection was renewed and increased, but the Pontifical Library at Avignon has only in part, and in later times, been taken into the Library of the Vatican. This latter is a new creation of the great humanist popes of the 15th century. Eugenius IV. planted the first seed, but Nicholas V. must be looked upon as the real founder of the library to which Sixtus IV. consecrated a definite abode, ornate and splendid, in the Court of the Pappagallo. Sixtus V. erected the present magnificent building in 1588, and greatly augmented the collection. The library increased upon various popes and librarians, among the most noteworthy of whom were Marcello Cervini, the first Cardinale Bibliotecario, later Pope Marshall II., Sirloin and A. Carafa. In 1600 it was further enriched by the acquisition of the valuable library of Fulvio Orsini, which contained the pick of the most precious libraries. Pope Paul V. (1605-1621) separated the library from the archives, fixed the progressive numeration of the Greek and Latin MSS., and added two great halls, called the Pauline, for the new codices. Under him and under Urban VIII. a number of MSS. were purchased from the Convento of Assisi, of the Minerva at Rome, of the Capranica College, &c. Especially noteworthy are the ancient and beautiful MSS. of the monastery of Bobbio, and those which were acquired in various ways from the monastery of Rossano. Gregory XV. (1622) received from Maximilian I., duke of Bavaria, by way of compensation for the money supplied by him for the war, the valuable library of the Elector Palatine, which was seized by Count Tilly at the capture of Heidelberg. Alexander VII. (1668), having purchased the large and beautiful collection formerly belonging to the dukes of Urbino, added the MSS. of it to the Vatican library. The Libreria della Regina, i.e. of Christina, queen of Sweden, composed of very precious manuscripts from ancient French monasteries, from St Gall in Switzerland, and others—all of the MSS. of Alexandre Petua, of great importance for their history and French literature, was purchased and in great part presented to the Vatican library by Pope Alexander VIII. (Ottoboni) in 1689, while other MSS. came in later with the Ottoboni library. Under Clement XI. there was the noteworthy purchase of the 54 Greek MSS. which had belonged to Pius II., and also the increase of the collection of Oriental MSS. Under Benedict XIV. there came into the Vatican library, as a legacy, the collections of the Marchese Petyou. These form the most valuable Italian editions, besides 185 MSS.; and by purchase, the Bibliotheca Ottoboniana, which, from its wealth in Greek, Latin, and even Hebrew MSS., was, after that of the Vatican, the richest in all Rome. Clement XIII. in 1758, Clement XIV. in 1769, and Pius VI. in 1775 were also beneficiaries. During three centuries the vast and monumental library grew with uninterrupted prosperity, but it was to undergo a severe blow at the end of the 18th century. In 1798, as a sequel to the Treaty of Tolentino, 500 MSS. picked from the most valuable of the different collections were sent to Paris by the victorious French to enrich the Bibliothèque Nationale and other libraries. These, however, were chiefly restored in 1815. Most of the Palatine MSS., which formed part of the plunder, found their way back to the university of Heidelberg. Pius VII. acquired for the Vatican the library of Cardinal Zelada in 1800, and among other purchases of the 19th century must be especially noted the splendid Cicognara collection of archaeology and art (1823); as well as the library in 40,000 vols. of Cardinal Angelo Mal (1850). Recent more important purchases, during the Pontificate of Leo XIII., have been the Borghese MSS., about 300 in number, representing part of the ancient library of the popes at Avignon; the entire precious library of the Barberrini; the Borgia collection De Propaganda Fide, containing Latin and Oriental MSS., and 500 incunabula.

Few libraries are so magnificently housed as the Biblioteca Vaticana. The famous Codici Vaticani are placed in the salone or great double hall, which is decorated with frescoes depicting ancient libraries and councils of the church. At the end of the great hall an immense gallery, also richly decorated, and extended to 1200 ft., opens out from right to left. Here are preserved in different rooms the codici Palatini, Regii, Ottoboniani, Capponianian, &c. The printed books only are on open shelves, the MSS. being preserved in closed cases. The printed books that were at first stored in the Borgia Apartment, now with the library of Cardinal Mai, constitute in great part the Museo Sala di Consultazioni, which was opened to students under the Pontificate of Leo XIII. Other books, on the other hand, are still divided into 1st and 2nd raccolta, according to the ancient denomination, and are stored in adjacent halls.

Well-reasoned calculations place the total number of printed books at 400,000 vols.; of incunabula about 4000, with many vellum copies; 500 Aldines and a great number of bibliographical rarities. The Latin manuscripts number 31,373; the Greek amount to 4148; the Oriental MSS., of which the computation is not complete, amount to about 4000. Among the Greek and Latin MSS. are some of the most valuable in the world, alike for antiquity and intrinsic importance. It is sufficient to mention the famous biblical Codex Vaticanus of the 4th century, the two Virgils of the 4th and 5th centuries, the Bembo Terence, the palimpsest De Republica of Cicero, conjectured to be of the 4th century, discovered by Cardinal Mai, and an extraordinary
number of richly ornamented codices of great beauty and costliness. The archives are apart from the library, and are accessible in part to the public under conditions. Leo XIII. appointed a committee to consider what documents of general interest might expeditiously be published.

The Biblioteca Vaticana is now open from October 1st to Easter every morning between 9 and 1 o'clock, and from Easter to June 20 from 8 o'clock to 12, with the exception of Sundays, Thursdays and the principal feast days.

Catalogues of special classes of MSS. have been published. The Oriental MSS. have been described by J. S. Assemani, Biblio-
teca orientalis Clementino-Vaticana (Rome, 1710-1728, 4 vols. folio), and Bibl. Vat. cod. MSS. catalogus ab S. E. e J. S. Assemani redactus (ib., 1736-1750, 3 vols. folio), and by Cardinal Mai in Script. Vat. nova collecta. The Coptic MSS. have been specially treated by G. Zoega (Rome, 1816, folio) and by F. G. Bonjour (Rome, 1869, 410). There are printed catalogues of the Capponi (1747) and the Cicognara (1820) libraries. The following catalogues have lately been printed: E. Stevenson, Codd. Palatini Graeci (1853), Codd. Gr. Reg. Scaligere et Phil. II. (1887); Feron-Battaglia et Cod. Ottoboni (1892), C. Codd. Urb. Graeci (1893), C. Codd. Urb. Latini (1895); E. Stevenson, Codd. Palatini Lat. tom. i. (1886); G. Salerno, Codici Capponiani (1897); M. Vattasso and P. Franchi de' Cavalieri, Codd. Lat. Vaticani, tom. i. (1902); C. Stornaiolo, Codices Urbani Latini, tom. i. (1902); E. Stevenson, Inventario dei libri stampati Palatino-Vaticani (1886-1891); and several volumes relating to Egyptian papyri by O. Marucchi. Some of the greatest treasures have been reproduced in facsimile.

The most important library in Italy for modern requirements is the Biblioteca Nazionale Centrale Vittorio Emanuele. From its foundation in 1875, incorporating the bibliotheca maior o secreta of the Jesuits in the Collegio Romano, and all the cloister libraries of the Province Romana which have come down to us from the high antiquity, it has now, by purchases, by donations, through the operation of the law, of the press increased to about 850,000 printed vols., and is continually being ameliorated. It possesses about 1600 incunabula and 6000 manuscripts. Not only among these are the Farnesini and the Sessorian MSS. of Santa Croce in Jerusalem, and some of these of the 6th to the 8th centuries are real treasures. The library has been recently reorganized. It is rich in the history of the renaissance, Italian and of Europe, of the 15th to 17th centuries. Its richest collections are the Rappresentazioni of the 16th and 17th centuries, 200 books printed on vellum, and a copy of collection of municipal histories and statutes, of testi di lingua and of maps. The Galileo collection numbers 908 MSS. The MS. portolani, 25 in number, are for the most part of the 16th century. Of particular interest is a manuscript which seems to be the original charts executed for Sir Robert Dudley (duke of Northumberland) in the preparation of his Arco del Mare. The library contains (1909) 571,698 printed vols., 20,222 MSS., 9037 incunabula, 15,674 xylographs, and a xylographic Biblia Pauperum. Amongst the MSS. are a rare Dante and autograph letters of Galileo, some poems in Tasso's autograph, and a fine series of illustrated service-books, with miniatures representing the history of the order from the 16th to the 17th century. One room is devoted to the works of Manzoni.

The Biblioteca Nazionale di Napoli, better known as the Braidense, founded in 1770 by Maria Theresa, consists of 243,000 printed vols. 1757 MSS. and over 3000 autographs. It comprises nearly 2300 books printed in the 15th century (including the works of the Minor Doctors and the early compositions of the several seem to be the original chart executed for Sir Robert Dudley (duke of Northumberland) in the preparation of his Arco del Mare. The library contains (1909) 571,698 printed vols., 20,222 MSS., 9037 incunabula, 15,674 xylographs, and a xylographic Biblia Pauperum. Amongst the MSS. are a rare Dante and autograph letters of Galileo, some poems in Tasso's autograph, and a fine series of illustrated service-books, with miniatures representing the history of the order from the 16th to the 17th century. One room is devoted to the works of Manzoni.

The Biblioteca Nazionale di Napoli, better known as the Braidense, founded in 1770 by Maria Theresa, consists of 243,000 printed vols. 1757 MSS. and over 3000 autographs. One room is devoted to the works of Manzoni.
centuries, including a fine first Homer; and several MS. maps and portolani, one dating from the end of the 14th century. The library contains about 389,100 printed vols., 7990 MSS. and 4217 incunabula.

The Biblioteca Nazionale di Palermo, founded from the Collegio Massimo of the Jesuits, with additions from other libraries of the suppressed order, is rich in 15th-century books, which have been elaborately described in a catalogue printed in 1875, and in Aldine and bibliographical curiosities of the 16th and following centuries. Among the curiosities of the 16th century, many being unique. The library contains 167,898 printed vols., 2550 incunabula, 1537 MSS.

The Biblioteca Nazionale Universitaria di Turin took its origin in the donation of the library of the Chiesa di San Pietro di Porta Palatina. It was made to the University by Vittorio Amedeo II. in 1720. The disastrous fire of January 1904 destroyed about 24,000 out of the 300,000 vols. which the library possessed, and of the MSS., the number of which was 4138, there survive now but 1500 in a more or less perfect condition. Among these were the palimpsests of Cicero, Cassiodorus, the Codex Theodosianus and the famous Livre d'Heures. What escaped the fire entirely was the valuable collection of 1095 incunabula, the most ancient of which is the Rationale Dinaricum Officium of 1490. Since that time the library has been enriched by new gifts, the most conspicuous of which is the collection of 30,000 vols. presented by Baron Alberico Lumbruno, principally relating to the French Revolution and comprising, among many other rarities, the premises of the Palazzo del Debito Publico. The Biblioteca Marciana, or library of St Mark at Venice, was traditionally founded in 1362 by a donation of MSS. from the famous Petrarch (1304-74), with the condition of their being copied and presented to the city. To these, in 1393, it was transferred to Modena by Cesare D'Este in 1598. Muratori, Zaccaria and Tiraboschi were librarians here, and made good use of the treasures of the library. It is particularly rich in MSS. of the 16th century. It was opened to the public in 1753. The number of these and of original drawings by the old masters amounts to 80,000 pieces; the printed volumes number 200,000, the incunabula 620, and the MSS. 1500. At Modena is the famous Biblioteca Estense, so called from a new foundation made by the Adriatic in 1441. It contains 77,000 printed vols., 3336 MSS., and 1904 autographs of the Campion collection. The oldest library at Naples is the Biblioteca Brancacciana, with 50,000 vols., and 170 MSS., most of which were given to the city by Cardinal Bessarione in 1468. The printed vols. number 417,314. The precious includes 12,106 MSS. of great value, of which more than 1000 Greek codices were given by Cardinal Bessarione. The number of MSS. is further augmented by a library of MSS., the collection of which consists of the old Library of the monastery of the Institute. The library of the Institute is a great many private and conventual libraries have been incorporated with the Marciana, which had its first abode in the Libreria del Sambonico, from which in turn it was transferred in 1534 to the premises of the palace in the Castello. The library has a rich collection of Greek, rare incunabula, and a great number of volumes, unique or exceedingly rare, on the subject of early geographical research. Amongst the MSS., is a Latin Homer, an invaluable codex of the laws of the Lombards, and the autograph MS. of Sarpi's History of the Church. It was founded in 1816. It was reopened in 1821.

Among the university libraries under government control some deserve special notice. First in historical importance comes the Biblioteca Estense of the University of Bologna, a library of 377,000 vols., 233,000 MSS., and 146 Bodleian editions. The University of Padua, a university of 12th century, the Avicenna, with manuscripts dated 1254, described by Matteo da Vicenza, and containing several interesting Peshito texts. Amongst the Italian MSS. is a rich assembly of municipal histories. Mezzofanti was for a long time the custodian here, and his own collection of books has been incorporated in the library, which is remarkable likewise for the number of early editions and Aldine which it contains. A collection of the manuscripts of Agostino Caracci is another special feature of worth. The grand hall with its fine furniture in walnut wood merits particular attention. The Biblioteca della Universita at Naples was established by Joachim Muratori in 1722. It contains about 150,000 printed vols., 12,000 MSS., and 2000 incunabula, 203 Aldines, and 156 Bodoni editions, but the most important incunabula and MSS. about the middle of the 19th century. Of the university libraries are those of Catania (1755), 130,000 vols.; Genoa (1773), 132,000 vols., 1588 MSS.; Pavia (1763), 250,000 vols., 1100 MSS.; Padua (200,000 vols., 2356 MSS.), which in 1910 was housed in a new building with 130,000 vols.; and lastly, the University of Monza, damaged in the earthquake of 1908, preserved, however, beneath its ruins the more important part of its furniture and fittings, and in 1910 was already restored to active work, as regards the portion serving for the reawakened Faculty of Law in the University.
has a 10th-century codex of Aristophanes and two 14th-century codices of Dante. At Vercelli the Biblioteca dell'Archivio Capitolare, the foundation of which can be assigned to no certain date, but must be referred to the early days when the barbarous conquerors, the Lombards, had established their footing in MSS., all of great antiquity and value. Amongst them is an Evangelium S. Eusebii in Latin, supposed to be of the 4th century; also the famous codex containing the Anglo-Saxon homilies which have been described by Mr. Hume, and the Sibylline Books (1841) there is also the Biblioteca Municipal with about 25,000 vols. There are libraries attached to colleges, churches and clubs, and most of the larger towns possess public libraries.

The MS. library in Rome is the Biblioteca Publica National of Rio de Janeiro (1807) now comprising over 250,000 printed vols., with many MSS. National literature and works connected with South America are special features of this library. Of the Biblioteca National de S.America the most important is the Biblioteca Municipal.

There are various provincial and public libraries throughout Brazil, doing good work, and a typical example is the public library of Maranhao.

The Biblioteca Nacional at Santiago is the chief library in Chile. The catalogue is printed, and is kept up by annual supplements. It possesses about 100,000 vols. There is also a University Library at Santiago, and a fairly good Biblioteca Publica at Valparaiso.

The Biblioteca Nacional at Lima was founded by a decree of the liberator San Martin on the 28th of August 1821, and placed in the house of the old convent of San Pedro. The nucleus of the library consists of the titles of the late Mr. R. S. de Montogo, and several monasteries, and a large present of books was also made by San Martin. The library is chiefly interesting from containing so many MSS. and rare books relating to the history of Peru in vice-regal times.

Spain and Portugal.

Most of the royal, state and university libraries of Spain and Portugal have government control and support. In Portugal the work of the universities is to a certain extent connected up, and an official bulletin is published in which the laws and accessions of the libraries are contained.

The chief library of the state is the Biblioteca Nacional (formerly the Biblioteca Real) at Madrid. The printed volumes number 600,000 with 200,000 pamphlets. Spanish literature is of course well represented, and, in consequence of the numerous accessions from the Biblioteca del Congreso, the classes of theology, history, &c., contain 30,000 MSS., including some finely illuminated codices, historical documents, and many valuable autographs. The collection of prints extends to 120,000 pieces, and was principally formed from the important series belonging to the late Prince Real de la Escorial. The books of the library are of the latest publication, and have one catalogue arranged under authors' names, and one under titles; the departments of music, maps and charts, and prints have subject-catalogues as well. There is a general index of the MSS., with special catalogues of the Greek and Latin codices and genealogical documents. The cabinet of medals is most valuable and well arranged. Of the other Madrid libraries it is enough to mention the Biblioteca de la Real Academia de la Historia, 1758 (20,000 vols. and MSS.), which contains some printed and MS. Spanish books of great value, including the well-known Salazar collection.

The history of the library of the Escorial (g.r.) has been given elsewhere. In 1808, before the invasion, the Escorial is estimated to have contained about 400,000 vols. In 1841, after the French occupation, the library was re-opened to Madrid, but when it was returned by Ferdinand, 10,000 vols. were missing. There are now about 40,000 printed vols. The Arabic MSS. have been described by M. Casiri, 1760-1779; and a catalogue of the Latin MSS. has been given by M. Caproni. The library contains the following:—

Among the libraries of Portugal the Biblioteca Nacional at Lisbon (1796) naturally takes the first place. In 1841 it was largely increased from the monastic collections, which, however, seem to have been taken up by the Biblioteca de historia and genealogia and the Biblioteca de historia da Inglaterra, and it contains about 155,000 vols., and that of Seville (1767) has 82,000 vols. Other cities in Spain possess provincial or university libraries open to students under various restrictions, among them may be mentioned the Biblioteca de la Universidad de Salamanca, the Biblioteca Provincial y Universitaria de Barcelona (1841) contains about 40,000 vols. Of printed and MS. books, of which there are about 400,000 vols., of printed books, among which theology, canon law, history and Portuguese and Spanish literature largely predominate. There is also a cabinet of 40,000 coins and medals. The Biblioteca da Academia, founded in 1780, is preserved in the suppressed convent.

Latin America.

Much interest in libraries has not been shown in south, central and other parts of Latin America. Most of the libraries which exist are national or legislative libraries.

As the libraries of the republic of Cuba are more Spanish than American in character, it will be convenient to consider them here. The chief libraries are in Havana, and the best are the Museo de la Historia del Arte, and the Biblioteca Publica Provincial. The Biblioteca Publica has within recent years been completely overhauled, and is now one of the most actively-managed libraries in Latin America.

Cuba is divided into twenty-nine states and territories of the Mexican republic about half have public libraries, and only a small proportion of the contents consists of modern literature. Many possess rare and valuable books, of interest to the bibliographer and student who have come from the libraries of the suppressed religious bodies. There is a large number of scientific and literary associations in the republic, each possessing books. The Society of Geography and Statistics, founded in 1851 in Mexico City, is the most important, and possesses about 3000 vols., of which are in the library.

After the triumph of the Liberal party the cathedral, university and conventual libraries of the city of Mexico came into the possession of the government, and steps were taken to form them into a national collection, but it was not finally organized until 1867, when the church of San Augustin was taken and fitted up for the purpose. In 1884 it was opened as the Biblioteca Nacional, and now possesses over 200,000 vols. Two copies of every book printed in Mexico must be presented to this library. Most of the libraries of Mexico, city or provincial, are subscription, and belong to societies and schools of various kinds.
of the Ordem Terceira da Penitencia. In 1836 the Academy acquired the library of that convent, numbering 30,000 vols., which have since been kept apart. The Archivo Nacional, in the same building, contains the archives of the kingdom, brought here after the destruction of the Monastery of St. Francis in 1768.

The Biblioteca Publica Municipal at Oporto is the second largest in Portugal, although only dating from the 9th of July 1833, the anniversary of the decapitation of D. Pedro, and when the memorable siege was raised. It was formed by the transfer of the collections of the Real Biblioteca do Porto. The regent (ex-emperor of Brazil) gave to the town the libraries of the suppressed convents in the northern provinces, the municipality undertaking to defray the expense of removing them. The collection now numbers over 60,000 printed books and MSS., and 130,000 among the school children. The Bibliothèque publique of Bruges (1798) contains 145,500 printed books and MSS., housed in a very artistic building, once the Tonlieu or dousane, 1477. The library of the old Biblioteca de la Ville dates from 1814, when on the foundation of the university the old Bibliothèque de la Ville was added to it. There are now 350,000 printed vols., pamphlets, MSS., &c. The Liège collection is augmented by the lectures of the fine arts, but is also augmented by M. Ulysse Capitaine, extends to 12,000 vols. and pamphlets. There are various printed catalogues. The Bibliothèques Populaires of Liège established in 1862, now number five, and contain the most important works. The Duke of Brabant bequeathed a part of his personal library of 5,000 vols. to Liège schools, and they are open as a rule only one part of the day. Every small town has a similar library, and a complete list of them, together with much other information, will be found in the Annaire de la Belgique scientifique, artistique et litteraire (Brussels 1908 and later issues).

The national library of Holland is the Koninklijke Bibliotheek at Hague, which was established in 1798, when it was decided to place the libraries of the provinces under the control of the defunct government bodies in order to form a library for the States-General, to be called the National Bibliothek. In 1805 the present name was adopted; and since 1815 it has become the national library. In 1848 the Barons of the Museum van Westreenen van Linschoten bequeathed the so-called hollondische Boeken, MSS., and prints to the country, and directed that they should be preserved in his former residence as a branch of the royal library. There are now upwards of 500,000 vols. of printed books, and the MSS. number 5,000, beginning history, and including many fine books and volumes of engravings, prints, and miniatures. Books are lent all over the country. The library boasts of the richest collection in the world of books on chess, Dutch incunabula, Elzevirs and Spinoza. There is one general written catalogue of the MSS. of 1845, which is also valuable, but by no means complete. A printed catalogue was issued, with four supplements down to 1811, and since 1866 a yearly list of additions has been published. Special mention should be made of the excellent catalogue of the incunabula published in 1886.

The next library in numerical importance is the famous Bibliothèque Academica Lugduno-Batavae, which dates from the foundation of the university of Leiden by William I., prince of Orange, on the 8th of February 1575. It has acquired many valuable additions from the books and MSS. of the distinguished scholars, Collius, Joseph Scaliger, Isaac Voss, Ruhnken and Hemsterhuis. The MSS. comprehend many of great intrinsic importance. The library of the Society of Natural Sciences of Leiden is included in this library. It is one of the richest in the national history and literature. The Arabic and Oriental MSS. known as the Legatuum Warinarianum are of great value and interest; and the collection of maps bequeathed in 1870 by J. J. Bosboom oftrecht will also be of great interest. The library has been since 1807 in a new building which was formerly a church of the Beguines, adapted in 1800 somewhat after the style of the British Museum. The catalogue (one alphabetical and one classified) are on slips, the titles being printed; a catalogue of the MSS. was printed in 1716, one of the books added between 1814 and 1847 and a supplementary part of MSS. only in 1850. A catalogue of the Oriental MSS. was published in 6 vols. (1851-1877). The Bibliothek der Rijksuniversiteit (1753) at Amsterdam contains over 100,000 vols.

The University Library at Utrecht dates from 1582, when certain conventual collections were brought together in order to form a public library, which was shortly afterwards enriched by the books belonging to the faculties of the university. The foundation of the university in 1536, the town library passed into its charge. Among the MSS. are some interesting cloister MSS. and the famous "Utrecht Psalter," which contains the oldest text of the Athanarian creed. The library has an annual supplement of 100 vols. with supplement in 1845, index from 1845-1855 in 8vo., and additions 1866-1870, 2 vols. 8vo. A catalogue of the MSS. was issued in 1877. The titles of MSS. are now printed in sheets and passed down for inspection. The manuscript collection is fine.

The basis of the University Library at Amsterdam consists of a collection of books brought together in the 15th century and preserved in the Nieuwe Kerk. At the time of the Reformaition in 1578 the Reformed Church in Amsterdam took possession of the Nieuwe Kerk for the use of the public till 1612, when they were transferred to the Athenaeum. Since 1877 the collection has been known as the University Library, and in 1881 it was removed to a building designed for the purpose in the gardens of the British Museum. The library includes the best collection of medical works in Holland, and the Bibliotheca Rosenthaliana of Hebrew and Talmudic literature is of great fame and value; a catalogue of the last was printed in 1875. The libraries of the Dutch Geographical
and other societies are preserved here. A general printed catalogue was issued in 6 vols. 8vo, Amsterdam (1856-1877); one describing the bequests of J. de Bosch Kemper, E. J. Potgieter and F. W. Rive, in 4 vols. 8vo, 1851-1858. A MSS. of Professor Mol in 48 vols. 8vo, published in 1860, and one of those of P. Camper in 1884. Other catalogues have been published up to 1902, including one of the MSS. The library contains about half a million volumes. There are also popular scripture and reading-rooms in all parts of the city, and in Rotterdam there is a movement of recent growth, in favour of training librarians on advanced English lines.

The library of the Koninklijk Bibliothek may be said to have taken place during the reign of Christian III, (1533-1559), who took pride in the possession of a wide choice MSS.; but the true founder was Frederick III. (1648-1705), who published one of his famous collections of Icelandic literature and the acquisition of Tycho Brahe's MSS. The present building (in the Christiansborg castle) was designed in 1667; during notable accessions may be mentioned the collections of C. Reitzer, the court physician (20,000 vols. and 500 MSS.) and Count de Thott; the last bequeathed 6,030 vols. printed before 1531, and the remainder of his books, over 100,000 vols., were eventually purchased. In 1793 the library was opened to the public, and it has 400,000 vols. Of interest are the contrivance of every book published within the kingdom must be deposited. The incunabula and block-books form an important series. There is a general knowledge in cataloguing in the use of reading; and an alphabetical one on 500 boxes for the Libraries. A good catalogue of the de Thott collection was printed in 12 vols. 8vo, (1759-1795); a catalogue of the French MSS. appeared in 1844; of Oriental MSS., 1846; of the Danish collection, 1875, 8vo. Annual reports are issued, and the library has been published since 1864. The library now contains over 750,000 vols.

The University Library, founded in 1482, was destroyed by fire in 1726, and re-established shortly afterwards. A copy of every Danish book was to be deposited. The MSS., include the famous Arne-Magnan collection. There are now 800,000 vols. in this library. The Stadsbibliotek of Aarhus (1902) possesses about 200,000 vols., and the Landsbørsalen Islands (National Library) has over 90,000 printed books and 5,500 MSS. In Copenhagen there are 11 popular libraries, in part by the city, and there are at least 50 towns in the provinces with public libraries and in some cases reading-rooms. An association promoting public libraries was formed in 1905, and in 1909 the minister of public instruction appointed a special association.

The chief library in Norway is the University Library at Christiania, established at the same time as the university, September 2nd, 1811, by Frederick VI. with a donation from the king of many thousands of duplicates of the Royal Library, Copenhagen, and since augmented by important bequests. Annual publications are issued and there are now over 420,000 vols. in the collection. The Deichman Bibliothek in Christiania was founded by Carl Deichmann in 1780 (now 300,000 vols.). In 1898 it was augment-
ized, and in 1903 the open shelf method was installed by Haakon Nyhus, the librarian, who had introduced it in the small town of Rennesmoe. The library is partly supported by endowment, partly by grants from the municipality, and to a large extent by a fine collection of books, and in 1888 it was augmented by a typical example of a progressive library. The Free Library at Bergen has about 90,000 vols. and has recently been re-housed in a new building. The Free Library at Trondhjem, with open shelves, has also been opened at Trondhjem. The Koninklijke Bibliotek in Copenhagen, Kongelige Vinderskabels Selskab at Trondhjem now contains about 120,000 vols.

Owing to the absence of small towns and villages in Norway, most of the library work is concentrated in the coast towns. The Royal Library at Stockholm was first established in 1586. The original collection was given to the university of Upsala by Gustavus II., that formed by Christina is at the Vatican, and the library brought together by Charles X. was destroyed by fire in 1697. The present library was organized around 1667. The Bibliotheca-Engstrom Library (14,500 printed books and 1,200 MSS.) rich in materials (for Swedish history) is now annexed to it. In 1708, medicine and mathematics are left to other libraries. Among the MSS. are MSS. of the 9th or 10th century, with its interesting Anglo-Saxon inscription, is particularly noteworthy. The catalogues are in writing, and are both alphabetical and classified; printed catalogues have been issued of portions of the MSS.

The present building was opened in 1882. The library now contains about 320,000 printed books and over 1,000 MSS. The Karolinska Institute in Stockholm, contains a library medicinal with numbering over 40,000.

The University Library at Uppsala was founded in 1626, from the remains of several convent libraries; he also provided an endowment. The chief library in this branch is the Codex Argenteus, containing the Greek and Arabic manuscripts of Ulfilas. The general catalogues in writing. A catalogue was printed in 1814; special lists of the foreign accessions are published each year from 1850; the Arabic, Persian and Turkish MSS. described by Tornberg, 1846. It now contains about 340,000 printed books and MSS. The library at Lund dates from the foundation of the university in 1668, and was based upon the old cathedral library. The MSS. include the le再度 archive.

There are about 200,000 vols. in the library. The Stadtbibliotek of Gothenburg contains about 100,000 vols., and has a printed catalogue.

Russia.

The imperial Public Library at St Petersburg is one of the largest libraries in the world, and now possesses about 800,000 printed vols. and 34,000 MSS., as well as large collections of maps, autographs, photographs, &c. The beginning of such a magnificent collection may be said to have been the books seized by the Czar Peter during his invasion of Courland in 1714; the library did not receive any notable augmentation, however, till the year 1795, when, by the acquisition of the famous Zalski collection, the Imperial Library suddenly attained a place in the first rank among great European libraries. The Zalski Library was formed by the Polish count Joseph Zalski, who collected at his own expense during forty-three years no less than 200,000 vols., which were added to by his brother Andrew, bishop of Cracow, by whom in 1747 the library was thrown open to the public. At his death it was left under the control of the Jesuit College at Warsaw; on the suppression of the order it was taken care of by the Commission of Education; and finally in 1795 it was transferred by Suworof to St Petersburg as a trophy of war. It then extended to 250,000 printed vols., and 10,000 MSS., but in consequence of the withdrawal of medical and illustrated works to enrich other institutions, hardly 200,000 vols. remained in 1810. Literature, history and theology formed the main features of the Zalski Library; the last class alone amounted to one-fourth of the whole number. Since the beginning of the 19th century, through the liberality of the sovereigns, the gifts of individuals, careful purchases, and the application of the law of 1810, whereby two copies of every Russian publication must be deposited here, the Imperial Library has attained its present extensive dimensions. Nearly one hundred different collections, some of them very valuable and extensive, have been added from time to time. They include, for example, the Tula Slavonic collection (1830), Tischendorff's MSS. (1858), the Dolgorukov Oriental MSS. (1859), and the Firkowsich Hebrew (Karaite) library collection (1862-1863), the libraries of Adelung (1858) and Tobler (1877), that of the Slavonic scholar Jungmann (1856), and the national library of Karazin (1867). This system of acquiring books, while it has made some departments exceedingly rich, has left others completely meagre. The library was not regularly opened to the public until 1814; it is under the control of the minister of public instruction. There are fine collections of Aldines and Elzevirs, and the numerous incunabula are instructively arranged.

The manuscripts include 26,000 codices, 41,340 autographs, 4,689 charters and 576 maps. The glory of this department is the celebrated Codex Sinaiticus of the Greek Bible, brought from the convent of St Catherine on Mount Sinai by Tischendorf in 1859. Other important Biblical and patristic codices are to be found among the Greek and Latin MSS.; the Hebrew MSS.
include some of the most ancient that exist, and the Samaritan collection is one of the largest in Europe; the Oriental MSS. comprehend many valuable texts, and among the French are some of great historical value. The general catalogues are in writing, but many special catalogues of the MSS. and printed books are also preserved.

The nucleus of the library at the Hermitage Palace was formed by the empress Catherine II., who purchased the books and MSS. of Voltaire and Diderot. In the year 1861 the collection amounted to 150,000 vols., of which nearly all relates to the history of art, were then transferred to the Imperial Library. There are many large and valuable libraries attached to the government departments in St Petersburg, and most of the academies and colleges and learned societies are provided with similar libraries.

The second largest library in Russia is in the Public Museum at Moscow. The class of history is particularly rich, and Russian early printed books are well represented. The MSS. number 5,000, including many ancient Slavonic codices and historical documents of value. One room is devoted to a collection of Masonic MSS., which comprehend the archives of the lodges in Russia between 1816 and 1821. There is a general alphabetical catalogue in writing; the catalogue of the MSS. has been printed, as well as those of some of the special collections. The large and valuable library now contains close upon 1,000,000 printed books and MSS. The Imperial University at Moscow (1755) has a library of over 310,000 vols., and the Duchovnaya Academy has 120,000 vols. The Imperial Russian Historical Library has 270,000 vols., and the Imperial National Library is estimated to contain about 1,000,000 vols. and most of the state institutions and schools are supplied with libraries. All the Russian universities have libraries, some of them being both large and valuable—Dorpat (1802) 400,000 vols., Charkov (1823) 180,000 vols.; Odessa (1865) 250,000 vols.; and Warsaw (1817) 550,000 vols. There are also communal or public libraries at Charkov (1886) 110,000 vols.; Warsaw (1852) 40,000 vols.; Riga, 90,000 vols.; Vilna (1865) 210,000 vols., and many other towns.

A text-book on library economy, based on Graessel and Brown, was issued at St Petersburg in 1904.

**Eastern Europe.**

At Athens the National Library (1842) possesses about 250,000 vols., and there is also a considerable library at the university. The Public Library at Corfu has about 40,000 vols.
Belgrade University Library has 60,000 vols., and the University Library of Sofia has 30,000 vols. Constantinople University in 1910 had a library in process of formation, and there are libraries at the Greek Literary Society (20,000 vols.) and Theological School (11,000 vols.).

**China.**

Chinese books were first written on thin slips of bamboo, which were replaced by silk or cloth scrolls in the 3rd century B.C., paper coming into use in the beginning of the 2nd century. The practice continued until the 16th century. There were no public libraries in the western sense.

The practice of forming national collections of the native literature originated in the attempts to recover the works destroyed in the burning of the books by the "First Emperor" (220 B.C.). In 190 B.C. the law for the suppression of literary works was repealed, but towards the close of the 1st century B.C. many vols. were still missing. Hsiao Wu (139-86 B.C.) formed the plan of Repositories, in which books might be stored, with officers to transcribe them. Liu Hsien (50-9 B.C.) was specially appointed to classify the literary works, and copies of important books were made and the resumé of their labours is a detailed catalogue with valuable notes describing 11,332 "sections" (volumes) by 652 authors. Similar national collections were formed by nearly every succeeding dynasty. The first provincial libraries were established in 1572, and the second, in 1612. The first of these has led to the formation of very large imperial, official and private collections of books. Large numbers of works, chiefly relating to Buddhism and Taoism, are also stored in many of the temples. Through the vols. are usually several, and frequently in many volumes. The histories and encyclopedia are mostly of vast dimensions. Collections of books are kept in wooden cupboards or on open shelves, placed on their sides, each set of (50) of volumes (or about 250 to 300 ft.) being kept in what is called a "hu." The back of the book is pasted on the edge (either the top or bottom in a European book) and so face outwards as it lies on the shelf. Catalogues are simple lists with comments on the books, not the systematic and scientific productions used in Western countries. There are circulating libraries in large numbers in Peking, Canton and other cities.

See E. T. C. Werner, "Chinese Civilisation" (in H. Spencer's *Descriptive Sociology*, p. 11x).  

**Japan.**

The ancient history of libraries in Japan is analogous to that of China, with whose civilization and literature it had close relations. Since about 1870, however, the great cities and institutions have established libraries on the European model. It is probable that one of the most important of these was the Imperial Cabinet (1885) at Tokio with over 500,000 vols., consisting of the collections of the various government departments, and is for official use alone. The University Library (1872) is the largest open to students and the public; it contains over 400,000 vols. of which over 100,000 are Chinese books. The Public Library in the main room (Toshio-Kwan) at Ueno Park (1872) was formed in 1872 and contains over 250,000 vols., of which about one-fifth are European books. At Tokio are also to be found the Ohashi Library (1902) with 60,000 vols., and the Rikkyo Library (1908) with 130,000 vols. and the Nanki Library (1889) with 86,000 vols. The library of the Imperial University of Kyoto contains nearly 200,000 vols., of which over 90,000 are in European languages. To this is attached the Fukukura Medical College with 11,000 vols. The Municipal Library of Kyoto (1898) contains 46,000 vols. Other important municipal libraries in Japan are those at Akita in the province of Ugo, 47,000 vols., at Mito, province of Hitachi (1898), and some at Sapporo, Sarat. However, the chief libraries are Buddhist, Yamauchi, province of Suo (1907), 23,000 vols. The libraries of the larger temples often contain books of value to the philologist. Lending libraries of native and Chinese literature have existed in Japan from very early times.

**Library Associations and Training.**

The first and largest association established for the study of librarianship was the American Library Association (1876). The Library Association of the United Kingdom was formed in 1877 as an outcome of the first International Library Conference, held at London, and in 1898 it received a royal charter. It publishes a *Year Book*, the monthly *Library Record*, and has also examined by international committees of professional men. It also publishes examinations in Literary History, Bibliography and Library Economy, and issues certificates and diplomas. There are also English and Scottish district library associations. The Library Assistants Association was formed in 1895 and has branches in different parts of England, Wales and Ireland. It issues a monthly magazine entitled *The Library Assistant*. There is an important Library Association in Germany which issues a year-book giving information concerning the libraries of the country, and a similar organization in Austria-Hungary which issues a magazine at irregular intervals. An Association of Archivists and Librarians was formed at Brussels in 1907, and there are similar societies in France, Italy, Holland and elsewhere. In every country there is now some kind of association for the study of librarianship, archives or bibliography. International conferences have been held at London, 1877; London, 1897; Paris (at Exhibition), 1905; St Louis, 1904; Brussels (preliminary), 1910; and Brussels, 1910.

**Library Periodicals.**—The following is a list of the current periodicals which deal with library matters, with the dates of their establishment and place of publication: *The Library Journal* (New York, 1876); *The Library* (London, 1889); *Public Libraries* (Chicago, 1896); *International Library World* (London, 1898); *The Library Assistant* (1898); *The Library Association Record* (1899); *Library Work* (Minneapolis, U.S., 1906); *Bulletin of the American Library Association* (Boston, 1907); *Revue des bibliothèques* (Paris, 1891); *De Bibliothekskunst* (Copenhagen, 1896); *Bibliographische Beilage* (1893); *Bibliographie des bibliotheken* (1894); *Bibliotheken* (1895); *De Bibliothekskunst* (Hague, 1907); *Bibliographische Berichte für Bibliotheken* (Copenhagen, 1906); *For Folk-og Barnboksamlinger* (Christiania, 1906); *Folkebibliotekslaget* (Stockholm, 1903); *Zentralblatt für Bibliothekswesen* (Leipzig, 1884); *Blätter für Volksbibliotheken und Volksbildung* (Leipzig, 1897); *Die Bibliographie des Bibliotheks- und Buchwesens* (ed. by Albert Gottschalk, 1904); *Die Bibliographie des Bibliotheks- und Buchwesens* (ed. by Adalbert Hertzschank, 1895); *Jahrbuch der Deutschen Bibliotheken* (Leipzig, 1902); *Minerva. Jahrbuch der gelehrten Welt* (Leipzig, 1895); *Mittathen der Bibliotheke der Bibliotheken* (Vienna, 1889); *Dansk Bibliotheksblad* (Copenhagen, 1894); *Bibliothekskritik* (Copenhagen, 1895); *Bibliotheksmagazin* (Leipzig, 1896); *Toozo-kan* (Nagoya, 1905); *Revista delle biblioteche e di Igiene* (Florence, 1890); *Bollettino delle biblioteche popolari* (Milan, 1907); *Revista de Archivos, Bibliotecas y Museos* (Madrid, 1897); *The Librarian* (Tokio, Japan, 1897).
LIBRATION—LICHENS

LIBRATION (Lat. libra, a balance), a slow oscillation, as of a balance; in astronomy especially the seeming oscillation of the moon around her axis, by which portions of her surface near the edge of the disk are alternately brought into sight and swung out of sight.

LICATA, a seaport of Sicily, in the province of Girgenti, 24 m. S.E. of Girgenti direct and 54 m. by rail. Pop. (1901) 22,031. It occupies the site of the town which Phintias of Acruras (Agrigentum) erected after the destruction of Gela, about 281 B.C., by the Mamertines, and named after himself. The river Salso, which flows into the sea on the east of the town, is the ancient Himera Meridionalis. The promontory at the foot of which the town is situated, the Foggio di San′ Angelo, is the Ecnomus (Eknomon) of the Greeks, and upon its slopes are scanty traces of ancient structures and rock tombs. It was off this promontory that the Romans gained the famous naval victory over the Carthaginians in the spring of 246 B.C., while the plain to the north was the scene of the defeat of Agathocles by Hamilcar in 310 B.C. The modern town is mainly important as a shipping port for sulphur.

LICENCE (through the French from Lat. licentia, licere, to be lawful), permission, leave, liberty, an abuse of liberty, licentiousness; in particular, a formal authority to do some lawful act. Such authority may be either verbal or written; when written, the document containing the authority is called a "licence." Many acts, lawful in themselves, are regulated by statutory authority, and licences must be obtained for the sale of alcoholic liquor see LIQUOR LAWS.

LICHEN (lichen ruber), in medical terminology, a papular or ulcerous disease of the skin, consisting of an eruption in small thickly set, slightly elevated red points, more or less widely distributed over the body, and accompanied by slight febrile symptoms.

LICHENS, in botany, compound or dual organisms each consisting of an association of a higher fungus, with a usually unicellular, sometimes filamentous, alga. The fungal part of the organism nearly always consists of a number of the Discomyces or Pyrenomyces, while the algal portion is a member of the Schizopyraceae (Cyanophyceae or Blue-green Algae) or of the Green Algae; only in a very few cases is the fungus a member of the Basidiomycetes. The special fungus which take part in the association are, with rare exceptions, not found growing separately, while the algal forms are constantly found free. The reproductive organs of the lichen are of a typically fungal character, i.e., are apothecia or perithecia (see DYCTIOCYANUS). The algal cells are never known to form spores while part of the lichen-thallus, they may do so when separated from it and growing free. The fungus thus clearly takes the upper hand in the association.

Owing to their peculiar dual nature, lichens are able to live in situations where neither the alga nor fungus could exist alone. The enclosed alga is protected by the threads (hyphae) of the fungus, and supplied with water and salts and, possibly, organic nitrogenous substances; in its turn the alga by means of its green or blue-green colouring matter and the sun's energy manufactures carbohydrates which are used in part by the fungus. An association of two organisms to their mutual advantage is known as symbiosis, and the lichen in botanical language is described as a symbiotic union of an alga and a fungus. This form of relationship is now known in other groups of plants (see BACTERIOLOGY and FUNGI), but it was first discovered in the lichens. The lichens are characterized by their excessively slow growth and their great length of life.

Until comparatively recent times the lichens were considered as a group of simple organisms on a level with algae and fungi. The green (or blue-green) cells were termed gonidia by Wallroth, who looked upon them as asexual reproductive cells. When it was later realized that they were not reproductive elements they were considered as mere outgrowths of the hyphae of the thallus which had developed chlorophyll. In 1865 De Bary suggested the possibility that such lichens as Collema, Ephere, &c., arose as a result of the attack of parasitic Ascomycetes upon the algae, Nostoc, Chroococcus, &c. In 1867 the observations of Pamintzin and Baranetzky showed that the gonidia, in certain cases, were able to live outside the lichen-thallus, and in the case of Physcia, Evernia and Cladonia were able to form zoospores. Baranetzky therefore concluded that a certain number, if not all of the so-called algae were nothing more than free living lichen-gonidia. In 1886 Schwendener put forward the really illuminating view—exactly opposite to that of Baranetzky—that the gonidia in all cases were algae which had been attacked by parasitic fungi. Although Schwendener supported this view of the "dual" nature of lichens by very strong evidence he identified fungal as well as algal gonidia with the free-living algae, yet the theory was received with a storm of opposition by nearly all lichenologists. These workers were unable to consider with equanimity the loss of the autonomy of their group and its reduction to the level of a special division of the fungi. The observations of Schwendener, however, received ample support from Bornet's (1873) examination of 60 genera. He investigated the exact relation of fungus and alga and showed that the same alga is able to combine with a number of different fungi to form lichens; thus Chroolepos umbrinus is found as the gonidia of 13 different lichen genera.

The view of the dual nature of lichens had hitherto been based on analysis; the final proof of this view was now supplied by the actual synthesis of a lichen from fungal and algal constituents. Rees in 1871 produced the sterile thallus of a Collema from its constituents; later Stahl did the same for three species. Later Bonnier (1886) succeeded in producing fertile thalli by sowing lichen spores and the appropriate algae upon sterile glass plates or portions of bark, and growing them in sterilized air (fig. i). Möller also in 1887 succeeded in growing small lichen-thalli without their algal constituent (gonidia) on nutritive solutions; in the case of Calicium pycnidia were actually produced under these conditions.

The thallus or body of the lichen is of very different form in different genera. In the simplest filamentous lichens (e.g. Ephere pubescens) the form of thallus is the form of the filamentous alga which is merely surrounded by the fungal hyphae (fig. 2). The next simplest forms are gelatinous lichens (e.g. Collemaeae); in these the algae are Chroococcaceae and Nostocaceae, and the fungus makes its way into the gelatinous membranes of the algal cells and ramifies there (fig. 3). We can distinguish this class of forms as lichens with a homomeric thallus, i.e. one in which the algae and fungi are equally distributed. The majority of the lichens, however, possess a stratified thallus in which the gonidia are found as a definite layer or layers embedded in a pseudo-parenchymatous mass of fungal hyphae, i.e. they are heteromeros (figs. 8 and 9). Obviously these two conditions may merge...
into one another, and the distinction is not of classificatory value.

In external form the heteromerosous thallus presents the following modifications. (a) The foliaceous (leaf-like) thallus, which may be either peltate, i.e. rounded and entire, as in Umbilicaria, &c., or variously lobed and lacinated, as in Sticta, Parmelia, Cetraria (fig. 4), &c. This is the highest stage of its development and is sometimes very considerably expanded. (b) The fruticose thallus may be either erect, becoming pendulous, as in Usnea (fig. 5), Ramalina, &c., or prostrate, as in Alectoria jubata, var. chalybeiformis. It is usually divided into branches and branchlets, bearing some resemblance to a miniature shrub. An erect cylindrical thallus terminated by the fruit is termed a podetium, as in Cladonia (fig. 7). (c) The crustaceous thallus, which is the most common of all, forms a mere crust on the substratum, varying in thickness, and may be squamose (in Sarcosoma), radulate (in Placodium), areolate, granulose or pulverulent (in various Lecanora and Lecidea). (d) The hypophyloedal thallus is often concealed beneath the bark of trees (as in some Parmeliaceae and Anthonia), or enters into the fibres of wood (as in Xylotrema and

Conidia.—It has been made clear above that the conidia are nothing more than algal cells, which have been ensnared by fungal hyphae and made to develop in captivity (fig. 1). Funstuck gives ten free living algae which have been identified as the conidia of lichens. Pleurococcus (Cystococcus) humicolus in the majority of lichens, e.g. Usnea, Cladonia, Physcia, Parmelia, Calicum, many species of Lecidea, &c., Trentepohlia (Chroolepus) umbria in many species of Verrucaria, Graphidium and Lecidea; Palmaella botryoides in Epigloea; Pleurococcus vulgaris in Acarospora, Dermatocarpon, Catillaria; Dactylolycoccus infusionum in Solorina, Nephomia;

After Sach, from De Baty's Vergleichende Morphologie und Biologie der Pilze, by permission of Wilhelm Engelmann.

Nostoc lichenoides in most of the Collemaceae; Rivularia rubida in Omphalaria; Lichina, &c., Polyccoccus punctiformis in Peltigera, Pan-naria and Stictina; Gloiocapsa polydermatica in Baeomyces and Omphalaria; Sirostriphon pulvinatus in Ephebe parvifolia. The majority of lichens are confined to one particular kind of conidium (i.e. species of alga) but a few forms are known (Lecanora granatina, Solorina crocea) which make use of more than one kind in their development. In the case of Solorina, for example, the principal alga is a green alga, Nostoc (a blue-green alga) is also found playing a subsidiary part as
lichen. In *L. graminina* the primary alga is *Pleurococcus*, the secondary, *Gleocapsa*.

**Cephalodia.**—In about 100 species of lichens peculiar growths are developed in the interior of the thallus which cause a slight projection of the upper or lower surface. These structures are known as *cephalodia* and they usually occupy a definite position in the thallus. They are distinguished by possessing as gonidia algae foreign to the ordinary part of the thallus. The foreign algae are always members of the Cyanophyceae and on the same individual and even in the same cephalodium more than one type of gonidium may be found. The function of these peculiar structures is unknown. Zulkal has suggested that they may play the part of water-absorbing organs.

The exact relation of gonidia and hyphae has been investigated especially by B. and B. also by Hedlund, and very considerable differences have been shown to exist in different genera. In *Physyma*, *Arnoldia*, *Phylliscum* and other genera the gonidia are killed sooner or later by special hyphal branches, *haustoria*, which pierce the membrane of the algal cell, penetrate the protoplasm and absorb the contents (fig. 11, C). In other cases, e.g. *Smonalis*, *Micarea*, the haustoria pierce the membrane, but do not penetrate the protoplasm (fig. 11, D). In many other cases, especially those algae possessing *Pleurococcus* as their gonidia, there are no penetrating hyphae, but merely around them of the hyphal investment; their increase in number leads to the rupture of the enclosing cortical layer and the soredia escape from the thallus as a powdery mass (fig. 12). Since they are provided with both fungal and algal elements, they are able to develop directly, under suitable conditions, into a new thallus. The soredia are the most successful method of reproduction in lichens, for not only are some forms nearly always without spore-formation and in others the spores largely abortive, but in all cases the spore represents only the fungal component of the thallus, and its success in the development of a new lichen-thallus depends on the chance meeting, at the time of germination, with the appropriate algal component.

**Conidia.**—Contrary to the behaviour of the non-lichen forming Ascomycetes the lichen-fungi show very few cases of ordinary conidial formation. Bornet describes free conidia in *Arnoldia saxatilis*, and *Placodium* and *Conidia*-formation has been described by Neubner in the Calicaceae.

**Spermatia.**—In the majority of genera of lichens small flask-shaped structures are found embedded in the thallus (fig. 13). These were investigated by Tulasne in 1853, who gave them the name *spermatia*. The lower, ventral part of the spermatogonium is lined by delicate hyphae, the *sterigmata*, which give minute to minute colourless cells, the *spermatia*. The sterigmata are either simple (fig. 13, C) or separate—the so-called arthrosterigmata (fig. 13, B). The spermatogonia open by a small pore at the apex, towards which the sterigmata converge and through which the spermatia escape (fig. 13). There are two views as to the nature of the spermatia. In one view they are mere asexual conidia, and the term *pycnocnidia* is accordingly applied since they are borne in structures like the non-sexual *pycnidia* of other fungi. In the other view the spermatia are the male sexual cells and thus are rightly named; it should, however, be pointed out that this was not the view of Tulasne, though we owe to him the designation which carries with it the sexual significance. The question is one very difficult to settle owing to the fact that the major of spermatia appear to be functionless. In favour of the conidal view is the fact that the in the case of *Collema* and a few other forms the spermatia have been made to germinate in artificial cultures, and in the case of *Calicium parietinum* Möller succeeded in producing a spermatogonia bearing thallus from a spermatium. For the germination of the spermatia in nature there is only the observation of Hedlund, that in *Catillaria denigrata* and *C. praesertis* a thallus may be derived from the spermatia under natural conditions. In relation to the view that the spermatia are sexual cells, or at least were primitively so, it must be pointed out that although the actual fusion of the spermatial nucleus with a female nucleus has not been observed, yet in a few cases the spermatia have been seen to fuse with a projecting portion (trichogynes) of the ascomycium, as in *Collema* or *Parmelia*, and there is very strong circumstantial evidence that fertilization takes place (see later in section on development of ascocarp). The resemblance of the spermatia and spermatogonia to those of Uredineae should be pointed out, where also there is considerable evidence for their original sexual nature, though they appear in that group to be functionless in all cases. The observations of Möller, &c., on the germination cannot be assumed to negative the sexual hypothesis for the sexual cells of *Ulothris* and *Ectocarpus*, for example.

![Diagram of Lichen Thallus](image)
are able to develop with or without fusion. The most satisfactory view in the present state of our knowledge seems to be that the spermatia are male cells which, while retaining their fertilizing action in a few cases are now mainly functionless. The female sexual organs, the anogonia, would thus in the majority of cases develop by the aid of some reduced sexual process or the ascomycetes be developed without relation to sexual organs. A further argument in support of this view is that it is in complete agreement with what we know of the sexuality of the ordinary, free-living ascomycetes, where we find both normal and reduced forms (see Fungi).

Fruit Bodies.—We find two chief types of fruit bodies in the lichens, the peritesium and apothecium; the first when the fungal element is a member of the Pyrenomycetes division of the Ascomycetes, the second when the fungus belongs to the Discomycetes division.

In the two genera of lichens—the Basidiolichens—in which the fungus is a member of the Basidiozymes, we have the fructification characteristic of that class of fungi: these are dealt with separately. The peritesium is very constant in form and the gonidia take no part.

There present various shapes of which the following are the principal types: (a) ellipsoid, which are large, rounded, without any distinct thalline margin (e.g. Usnea, Fucus, etc.); (b) lecanorine, or scutelliform, which are orbicular and surrounded by a distinct, more or less prominent thalline margin (e.g. Parmelia, Lecanora), having sometimes also in addition a proper one (e.g. Thelephora, Urecoschial); (c) lecidea, or patelliform, which are typically orbicular, with only a proper margin (e.g. Leccida), sometimes obsolete, and which are occasionally irregular in shape, angular or flexuose (e.g. Leccidaurana, L. myrmecina), complicated and gyrose (e.g. Gymnopora), and even stipitate (e.g. Basidioschizae).

Illustrious, which are of very irregular figure, elongated, branched, or flexuose, with only a proper margin (e.g. Xylariophora, Graphis, etc.).

The fungi are either non or none (e.g. some Arthoniaceae), and often very variable even in the same species. In colour the apothecia are extremely variable, and it is but rarely that they are the same colour as the thallus (e.g. Usnea, Ramalina). Usually they are of different colour, and may be black, brown, yellowish, or also frequently bears, rusty-red, orange-red, yellow, or of various intermediate shades. Occasionally in the same species their colour is very variable (e.g. Lecanora metabolida, Leccida decorata), while sometimes they are white or glaucous, rarely greenish, pruinose. Leccida apothecia, which are not black, but otherwise variously coloured, are termed blasticine.

The two principal parts of which an apothecium consists are the hypothecium and the hymenium, or thecium. The hypothecium is the basal part of the apothecium on which the hymenium is borne; the latter consists of ascii (thecae) with ascospores, and paraphyses. The paraphyses (which may be absent entirely in the Pyrenolichens) are erect, colourless filaments which are usually dilated and coloured at the apex; the apices are usually cemented together into a definite layer, the epistoma (Fig. 14). The spores themselves may be unicellular without a septum or multicellular with one or more septa. Sometimes the two cavities are restricted to the two ends of the spore, the polar-lobate type and the two loculi may be united.

The thalline margin (margo thallinosus) is the projecting edge of a special layer of thallus, the amphithecium, round the actual apothecium; the proper margin (margo proprius) is the projecting edge of the apothecium itself.
LICHENS

by a narrow channel (fig. 15). At other times the spores are divided by both transverse and longitudinal septa producing the muriform (murali-divided) spore so called from the resemblance of the individual chambers to the stones in a wall. The very large single spores of Pertusaria have been shown to contain numerous nuclei and when they germinate develop a large number of germ tubes.

Development of the Ascomycetes.—As the remarks on the nature of the spermia show, the question of the sexuality of the lichens has been hotly disputed in common with that of the Ascomycetes. As indicated above, the weight of evidence seems to favour what has been put forward in the case of the non-lichen-forming fungi (see Putex), that in some cases the ascogonium develop as a result of a previous fertilization by spermia, in other cases the ascogonium develop without such a union, while in still other

cases the reduction goes still farther and the ascogenous hyphae instead of developing from the ascogonium are derived directly from the vegetative hyphae.

The first exact knowledge as to the origin of the ascocarp was the work of Stahl on Cladonia in 1877. He showed that the archicarp consisted of two parts, a lower coiled portion, the ascogonium, and an upper portion, the trichogyne, which projected from the thallus. Only when a spermium was found attached to the trichogyne did the further development of the ascogonium take place. From these observations he drew the natural conclusion that the spermium was a male, sexual cell. This view was hotly contested by many workers and it was sought to explain the trichogyne—without much success—as a respiratory organ, or as a boring organ which made a way for the developing apothecium. It was not till 1918, however, that Stahl's work received confirmation and addition at the hands of Baur (fig. 16). The latter showed that in Cladonia cristata there are two kinds of thalli, one with numerous apothecia, the other quite sterile or bearing only a few. The sterile thalli possessed no spermogonia, but were found to show sometimes as many as 1000 archicarps with trichogyne; yet none or very few came to maturity. The fertile thalli were shown to bear either spermogonia or trichogyne. Furthermore, it should be noted that after the fusion of the spermia with the trichogyne the transverse walls of the organ become perforated.

There was thus very strong circumstantial evidence in favour of fertilization, although the male nucleus was not traced. The further work of Baur, and that of Darbishire, Funstuck and Lindau, have shown that in a number of other cases trichogyne, ascogonium, and trichogyne have been present. Thus ascogonia with trichogyne have been observed in Endocarpon, Collema, Pertusaria, Leccana, Gyrophora, Parmelia, Ramalina, Physcia, Anaphyaxis and Cladonia. In Nechomum, Peligeria, Peltigera and Solarina a coagonia without trichogyne have been observed. In Collema and a form like Xanthoria parietina it is probable that actual fertilization takes place, and possibly also in some of the other forms. It is probable, however, that in the majority of cases the ascogonium develop without normal fertilization, as is necessarily the case where the ascogonium have no trichogyne or the spermia are absent. In these cases we should expect to find some reduced process of fertilization similar to that of

Humaria granulata among the ordinary Ascomycetes, where in the absence of the antheridia the female nucleus fuse in pairs. In other lichens we should expect to find the ascogenous hyphae arising directly from the vegetative hyphae as in Humaria granulata among the ordinary fungi, where the sperm is associated with the fusion of vegetative nuclei. It is possible that Solarina saccata as a class. Cytological details of nuclear behaviour among the lichens are, however, difficult to obtain owing to the slow growth of these forms and the often refractory nature of the material in the matter of preparation for microscopical examination.

Evolution of Spores.—The spores are ejected from the apothecia and perithecia as in the fungi by forcible evacuation from the ascus. In the majority of forms it is clear that the soredia, rather than the ascogonium, is the more important part in lichen distribution as the development of the ordinary spores is dependent on their finding the proper ascogonium. In various species of material in the matter of preparation for microscopical examination.

Basiolichens.

As is clear from the above, nearly all the lichens are produced by the association of an ascomycetous fungus with algae. For some obscure reason the Basidiomycetes do not readily form lichens, so that only a few forms are known in which the fungal element is a member of this family. The two best-known genera are Cora and Dictyoneura; Corella, whose hymenium is unknown, is also placed here by Wainio. The so-called Gasterolichens, Trichocoma and Emericella, have been shown to be merely ascomycetous fungi. Clavaria sulphurea, however, has apparently some claims to be considered as a Basidiolichen, since the base of the fruit body and the thallus from which it arises, according to Coker, always shows a mixture of hyphae and algae.

The best-known species is Cora pratonia, which is grown in tropical regions growing on the bare earth and on trees; the gonidia belong to the genus Chroococcus while the fungus belongs, apparently, to the Thelephorae (see Fungi). This lichen seems unique in the fact that the fungal element is also found growing and fruiting entirely devoid of algae, while in the

Fig. 14.—Diagram showing Apothecia in Section and surrounding Portion of Thallus, and special terms used to designate these parts.

Fig. 15.—Vertical Section of Apothecium of Xanthoria parietina. a, Paraphyses. b, Asci (thecae) with binocular spores. c, Hypothecium.

Fig. 16.—Cora pratonia. A, Viewed from above; B, From below; h, hymenium. (Nat. size.)
lichens the fungus portion seems to have become so specialized to its symbiotic mode of life that it is never found growing independently.

The genus Dictyonema has gonidia belonging to the blue-green alga, Scytomena. When the fungus predominates in the thallus it has a bracket-like mode of growth and is found projecting from the branches of trees with the hymenium on the under side. When the alga is predominant it forms felted patches on the bark of trees, the Laudatae form. It is said that the fungus of Cora pavorum and of Dictyonema is identical, the difference being in the nature of the alga.

Mode of Life.

Lichens are found growing in various situations such as bare earth, the bark of trees, dead wood, the surface of stones and rocks, where they have little competition to fear from ordinary plants. As is well known, the lichens are often found in the most exposed and arid situations; in the extreme polar regions these plants are practically the only vegetable forms of life. They owe their capacity to live under the most inhospitable conditions to the dual nature of the organism, and to their capacity to withstand extremes of heat, cold and drought without destruction. On a bare rocky surface a fungus would die from want of organic substance and an alga from drought and want of mineral substances. The lichen, however, is able to grow as the alga supplies organic food material and the fungus has developed a battery of acids (see below) which enable it to dissolve the most resistant rocks. It is owing to the power of disintegrating by both mechanical and chemical means the rocks on which they are growing that lichens play such an important part in soil-production. The resistance of lichens is extraordinary; they may be cooled to very low temperatures and heated to high temperatures without being killed. They may be dried so thoroughly that they can easily be reduced to powder yet their vitality is not destroyed but only suspended; on being supplied with water they absorb it rapidly by their general surface and renew their activity. The life of many lichens thus consists of alternating periods of activity when moisture is plentiful, and completely suspended animation under conditions of dryness. Though so little sensitive to drought and extremes of temperature lichens appear to be very easily affected by the presence in the air of noxious substances such as are found in large cities or manufacturing towns. In such districts lichen vegetation is entirely or almost entirely absent. The growth of lichens is extremely slow and many of them take years before they arrive at a spore-bearing stage. Xanthoria parietina has been known to grow for forty-five years before bearing apothecia. This slowness of growth is associated with great length of life and it is probable that individuals found growing on hard mountain rocks or on the trunks of aged trees are many hundreds of years old. It is possible that specimens of such long-lived species as Leccia geographica actually outlive in longevity the oldest trees.

Relation of Fungus and Alga.

The relation of the two constituents of the lichen have been briefly stated in the beginning of this article. The relation of the fungus to the alga, though it may be described in general terms as one of symbiosis, partakes also somewhat of the nature of parasitism. The algal cells are usually controlled in their growth by the hyphae and are prevented from forming zoospores, and in some cases, as already described, the algal cells are killed sooner or later by the fungus. The fungus seems, on the other hand, to stimulate the algal cells to special development, for those in the lichen are larger than those in the free state, but this is not necessarily adverse to the idea of parasitism, for it is well known that an increase in the size of the cells of the host is often the result of the attacks of parasitic fungi. It must be borne in mind that the exact nutritive relations of the two constituents of the lichen have not been completely elucidated, and that it is very difficult to draw the line between symbiosis and parasitism. The lichen algae are not alone in their specialization to the symbiotic (or parasitic) mode of life, for, as stated earlier, the fungus appear in the majority of cases to have completely lost the power of independent development, since with very rare exceptions they are not found alone. They also differ very markedly from true living fungi in their chemical reactions.

Chemistry of Lichens.

The chemistry of lichens is very complex, not yet fully investigated and can only be very briefly dealt with here. The wall of the hyphae of the fungus is not a true cell wall and consists of protoplasmic fractions of cellulose but older material shows somewhat different reactions, similar to those of the so-called fungus-cellulose. In many lichen-fungi the wall shows various chemical modifications. In numerous lichens, e.g., as Usnea filipendula, the wall contains lecanorin, a gummy substance which swells in cold water and dissolves in hot. Besides this substance, a very similar one, isolichenin, is also found which is distinguished from lecanorin by the fact that it dissolves in cold water and turns blue under the reaction of Iodine. The calcium oxalate is a very common substance, especially in crustaceous lichens; fatty oil in the form of drops or as an infiltration in the membrane is also common; it sometimes occurs in special cells and extreme cases may represent 10% of the dry substance as in Verrucaria calcicola, Biotella immersa.

Colouring Matters.—Many lichens, as is well known, exhibit a vivid colouring which is usually due to the incrustation of the hyphae with crystalline excretory products. These excretary products have been given many an academic name and hence are generally known as lichen-acids. A large number of these compounds, which are mostly benzene derivatives, have been isolated and more or less closely investigated. They are characterized by their insolubility or very slight solubility in water; as examples may be mentioned erythric acid in Roccella and Lecanora; evernic acid in species of Evernia, Ramalina and Ciadamia; lernic acid in Lecanora, Gyrophora. The so-called chrysophanic acid found in Xanthoria Physcia is not an acid but a base and is not a specific colouration.

Colour Reactions of Lichens.—The classification of lichens is unique in the fact that chemical colour reactions are used by many lichenologists in the discrimination of species, and these reactions are included in the specific diagnoses. The substances used as tests in these reactions are caustic potash and calcium hypochlorite; the former being the substance dissolved in an equal weight of water and the latter a saturated extract of bleaching powder in water. These reagents are represented by the symbol K and CaCl respectively, and the presence or absence of the colour reactions are represented thus, K+, CaCl+, or K-, CaCl-. If the cortical layer should exhibit positive reaction and the medulla negative reaction with both reagents, the reaction result is represented thus, K+CaCl++. If a reaction is only produced after the consecutive addition of the two reagents, this is symbolized by K(CaCl)+. A solution of iodine is also used as a reagent and failed to produce any reaction with the substratum or spores may give with this reagent. The objection to the use of these colour reactions is due to the indefinite nature of the reaction and the doubt as to the constant presence of a definite chemical compound in a given species. A yellow colour withSwieca potash and iodine may be produced by amorphous ferric acid, thamnic acid, &c. Again in the case of Xanthoria parietina vulpinic acid is only to be found in young thalli growing on sandstone; in older forms or in those growing on another substratum it is not to be detected. A similar relation holds for the formation and the nature of the substratum has been observed in many lichens. Considerations such as these should make one very wary in placing reliance on these colour reactions for the purposes of classification.

Economic Uses of Lichens.

In the arts, as food and as medicine, lichens have been highly esteemed, though others are not now employed for the same purposes as formerly.

1. Lichens Used in the Arts.—Of these the most important are such as yield, by maceration in ammonia, the dyes known in commerce as archil, cudbear and litmus. These, however, may with propriety be regarded as but different names for the same pigments, the variations in the character of which are attributable to the different modes in which the pigments are manufactured. Archil proper is derived from several species of Roccella (e.g. R. Montaguei, R. tinctoria), which yield a rich lilac purple dye; it once fetched a high price in the market. Of considerable value is the “perelle” prepared from Lecanora parea, and used in the preparation of a red or crimson dye. Inferior to this is cudbear, derived from Lecanora tartarea, which was formerly very extensively employed by the dyers of North Europe for giving a scarlet or purple colour to woollen cloths. By adding certain alkalies to the other ingredients used
LICHENS

in the preparation of these pigments, the colour becomes indigo-
blue, in which case it is the limus of the Dutch manufacturers.
Amongst other lichens affording red, purple or brown dyes may
be mentioned Ramalina sacculata, Parmelia saxatilis and P.
aphalodes, Umbilicaria pulsatula and several species of
Gyrophora, Urectaria splendens, all of which are more or less
employed as domestic dyes. Yellow dyes, again, are derived from
Chlorella vulgaris, Platygyra juniperinum, Parmelia caperata
and P. conspersa, Physcia flavicans, Ph. paretina and Ph.
lychna, though like the preceding they do not form articles of
commerce, being merely used locally by the natives of the
regions in which they occur most plentifully. In addition to
these, many exotic lichens, belonging especially to Parmelia
and Sistia (e.g. Parmelia tinctorum, Sistia argyreae), are rich in
colouring matter, and, if obtained in sufficient quantity, would
yield a dye in every way equal to archil. These pigments
primarily depend upon special acids contained in the thallii
of lichens, and their presence may readily be detected by means of
the reagents already noticed. In the process of manufacture,
however, they undergo various changes, of which the chemistry
is still but little understood. At one time also some species were
used in the arts for supplying a gum as a substitute for
gum-arabic. These were chiefly Ramalina fraxinea, Evernia
prunastri and Parmelia physodes, all of which contain a consider-
able proportion of gummy matter (of a much inferior quality,
however, to gum-arabic), and were employed in the process
of calico-printing and in the making of parchment and cardboard.
In the 17th century some filamentose and fruticose lichens,
viz. species of Usnea and Ramalina, also Evernia furfuracea and
Cladonia rangiferina, were used in the art of perfumery. From
their supposed aptitude to imbibe and retain odours, their
powder was the basis of various perfumes, such as the celebrated
"Poudre de Cypre" of the hairdressers, but their employment
in this respect has long since been abandoned.

2. Nutritive Lichens.—Of still greater importance is the
capacity of many species for supplying food for man and beast.
This results from their containing starchy substances, and in
some cases a small quantity of saccharine matter of the nature of
manitane. One of the most useful nutritious species is Cetraria
islandica, "Iceland moss," which, after being deprived of its
bitterness by boiling in water, is reduced to a powder and made
into cakes, or boiled and eaten with milk by the poor Icelanders,
whose sole food it often constitutes. Similarly Cladonia rangi-
ferina and Cl. sylvatica, the familiar "reindeer moss," are
frequently eaten by man in times of scarcity, after being powdered
and mixed with flour. Their chief importance, however, is that
in Lapland and other northern countries they supply the winter
food of the reindeer and other animals, who scrape away the snow
and eagerly feed upon them. Another nutritious lichen is the
"Tripe de Roche" of the arctic regions, consisting of several
species of the Gyrophorei, which when boiled is often eaten by
the Canadian hunters and Red Indians when pressed by hunger.
But the most singular edible lichen of all is the "manna lichen,"
which in times of drought and famine has served as food for large
numbers of men and cattle in the arid steppes of various countries
stretching from Algiers to Tartary. This is derived chiefly
from Lecanora esculenta, which grows unattached on the ground
in layers from 3 to 6 in. thick over large tracts of country in
the form of small irregular lumps of a greyish or white colour.
In connexion with their use as food we may observe that of
recent years in Scandavia and Russia an alcoholic spirit has
been distilled from Cladonia rangiferina and extensively con-
sumed, especially in seasons when potatoes were scarce and
dear. Formerly also Sistia pulmonaria was much employed in
brewing instead of hops, and it is said that a Siberian monastery
was celebrated for its beer which was flavoured with the
bitter principle of this species.

3. Medicinal Lichens.—During the middle ages, and even in
some quarters to a much later period, lichens were extensively
used in medicine in various European countries. Many species
had a great repute as demulcents, febrifuges, astringents, tonics,
purgatives and anthelmintics. The chief of those employed
for one or other, and in some cases for both, of these purposes
were Cladonia pyxidata, Usnea barbata, Ramalina farinacea,
Evernia prunastri, Cetraria islandica, Sistia pulmonaria,
Parmelia saxatilis, Xanthoria parietina and Pertusaria amara.
Others again were believed to be endowed with specific virtues,
e.g., Pettigera canina, which formed the basis of the celebrated
"pulvis antilysus" of Dr Mead, long regarded as a sovereign
cure for hydrophobia; Platygyra juniperinum, lauded as a specific
in jaundice, no doubt on the similia similibus principle from a
resemblance between its yellow colour and that of the jaundiced
skin; Pelidice aphthosa, which on the same principle was regarded
by the Swedes, when boiled in milk, as an effectual remedy for
the aphthae or rash on their children. Almost all of these virtues,
general or specific, were imaginary; and at the present day,
except perhaps in some remoter districts of northern Europe,
only one of them is employed as a remedial agent. This is the
"Iceland moss" of the druggists' shops, which is undoubtedly
an excellent demulcent in various dyspeptic and chest complaints.
No lichen is known to be possessed of any poisonous properties
to man, although Chlorella vulgaris is believed by the Swedes to
be so. Zukal has considered that the lichen acids protect the
lichen from the attacks of animals; the experiments of Zopfi,
however, have cast doubt on this; certainly lichens containing
very bitter acids are eaten by mites though some of the acids
appear to be poisonous to frogs.

Classification.

The dual nature of the lichen thallus introduces at the outset
a classificatory difficulty. Theoretically the lichens may be
classified on the basis of their algal constituent, on the basis of
their fungal constituent, or they may be classified as if they were
homogeneous organisms. The first of these systems is impractic-
able owing to the absence of algal reproductive organs and the
similarity of the algal cells (gonidia) in a large number of different
forms. The second system is the most obvious one, since the
fungus is the dominant partner and produces reproductive
organisms. The third system was that of Nylander and his followers,
who did not accept the Schwenderian doctrine of duality. In
actual practice the difference between the second and third
methods is not very great since the fungus is the producer of
the reproductive organs and generally the main constituent.
Most systems agree in deriving the major divisions from the characters
of the reproductive organs (perithecia, apothecia, or basidiospore
bearing fructification), while the characters of the algal cells
and those of the thallus generally are used for the minor divisions.
The difference between the various systems lies in the relative
importance given to the reproductive characters on the one hand
and the vegetative characters on the other. In the system
(1854-1855) of Nylander the greater weight is given to the latter,
while in more modern systems the former characters receive
the more attention.

A brief outline of a system of classification, mainly that of
Zahlbruckner as given in Engler and Prantl's Pflanzenfamilien,
is outlined below.

There are two main divisions of lichens, Ascolichenes and
Basidiolichenes, according to the nature of the fungal element,
whether an ascomycete or basidiomycete. The Ascolichenes
are again divided into Pyrenocarpeae or Pyrenolichenes and
Gymnocarpeae or Discolichenes; the first having an ascocarp
of the nature of a perithecium, the second bearing their ascospores
in an open apothecium.

Pyrenolichenes

Series I. Perithecium simple not divided.

a. With Pleurococcus or Palmeda gonidia.

Morioaceae, Verrucariaceae, Pyrenothecaceae.

b. With Chroogomphus gonidia.

Pyrenulaceae, Paratheliaceae.

c. With Phytolecidium or Cephaloporus gonidia.

Strigulaceae.

d. With Nostoc or Scytonema gonidia.

Pyrenidiaceae.

Series II. Perithecia divided or imperfectly divided by cross-walls.

Mycocarpaceae with Palmeda or Chroogomphus gonidia.
LICHENS

Disclichen

Series I. Coniciarpaceae. The paraphyses branch and form a network (capillitium) over the asci, the capillitium and ejected spores forming a long persistent powdery mass (mezium).

Caliciaceae, Cypheliciaceae, Sphaerophoraceae.

Series II. Graphidinae. Apothecia seldom round, usually elongated-ellipsoid, no capillitium.

Arthoniaceae, Graphidaceae, Roccellaceae.

Series III. Cylciarpaceae. Apothecium usually circular, no capillitium.

A. Spores usually two-celled, either with a strongly thickened cross-wall often perforated by a narrow canal or with cross-wall only slightly thickened. In the first case the spores are usually colourless, the second case always brown.

Buelliacaceae, Physciaceae.

B. Spores unicellular, parallel-multicellular or muriform, usually colourless, cross-walls usually thin.

a. Thallus always gelatinous.

Goniadia always belonging to the Cypselhaceae, Lichinaeae, Ephiaceae, Collemaeae, Pyrenoporeae.

β. Thallus not gelatinous.

Coniocondaceae, Lecideaceae, Cladoniaceae, Lecanoraeeae, Pertusariaeae, Peligerarieae, Stictacaceae, Pannariaceae, Gyrophoraceae, Parmelaceae, Cladoniaceae, Usneaceae.

Basiidilichen (Hymenolithicen)

Corn, Dictyonema (incl. Lauderii), Corella (doubtfully placed here as the hymenium is unknown).

Habitat and Distribution of Lichens.

1. Habitats.—These are extremely varied, and comprise a great number of very different substrata. Chiefly, however, they are the bark of trees, rocks, the ground, mosses and, rarely, perennial leaves. (a) With respect to corticole lichens, some prefer the rugged bark of old trees (e.g., Ramalin, Parmelia, Sietie, S Hipetidae) and others the smooth bark of young trees and shrubs (e.g., Graphidetum and some Lecidea). Many are found principally in large forests (e.g., Usneae, Acroconidium); while a few occur especially on trees by roadsides (e.g., Physco pietina and Ph. pululacea). In connexion with corticolous lichens may be mentioned those lichis species which grow on decayed, or decaying wood of trees and on old plates (e.g., Calicii, various Lecidea, Xyloderma), (b) As to saxicolous lichens, which occur on rocks and stones, they may be divided into two sections, viz. calcicolous and calcifugous. To the former belong such as are found on calcareous and cretaceous rocks, and the mortar of walls (e.g., Lecanora calcarea, Lecidea calcivora and several Vernicarieae), while all other saxicolous lichens may be regarded as belonging to the latter, whatever may be the mineralogical character of the substratum. It is here worthy of notice that the apothecia of several calcicolous lichens (e.g., Lecanora Pseudostis, Lecidea calcivora) have the power of forming minute cavities in the rock, in which they are partially buried. (c) With respect to terrestrial species, some prefer peaty soil (e.g., Cladonia, Leveida decalorata), others calcareous soil (e.g., Lecanora crocea, Lecidea decipiens), others sandy soil or hardened mud (e.g., Collema liminum, Peltigera venosa); while many may be found growing on all kinds of soil, from the sands of the sea-shore to the granitic debris of lofty mountains, with the exception of course of cultivated ground, there being no agrarian lichens. (d) Muscicolous lichens are again such as are most frequently met with on decayed mosses and Jungermannia, whether on the ground, trees or rocks (e.g., Leptogium muscicola, Gymnopus calcidicola). (e) The epiphyllous species are very peculiar as occurring upon perennial leaves of certain trees and shrubs, whose vitality is not at all affected by their presence as it is by that of fungi. In so far, however, as is known, they are very limited in number (e.g., Leveida, Botulice, Strigula).

Sometimes various lichens occur abnormally in such unexpected habitats as dried dung of sheep, bleached bones of reindeer and whales, old lead, iron and glass, in districts where the species are abundant. It is apparent that in many cases lichens are quite indifferent to the substrata on which they occur, whence we infer that the preference of several for certain substrata depends upon the temperature of the locality or that of the special habitat. Thus in the case of saxicolous lichens the mineralogical character of the rock has of itself little or no influence upon lichen growth, which is influenced more especially and directly by their physical properties, such as their capacity for retaining heat and moisture. As a rule lichens grow commonly in open exposed habitats, though some are found only or chiefly in shady situations; while, as already observed, scarred any occur where the atmosphere is impregnated with smoke. Many species also prefer growing in moist places by streams, lakes and the sea, though very few are normally and probably none entirely, aquatic, being always at certain seasons exposed for a longer or shorter period to the atmosphere (e.g., Lichina, Lepidotium ritualis, Endocarpum flava, Verrucarcaris aquatica). Some species are entirely parasitical on other lichens (e.g., various Lecideae and Pyrenorcarpi), and may be peculiar to one (e.g., Lecidea vivellinaria) or common to several species (e.g., Habrothallus peltariformis). A few, generally known as erratic species, have been met with growing upon unprepared to any substratum (e.g., Porina varia, var. concentrica, Lecanora esculenta); but it can hardly be that these are really free ab inital (vide Crambne in Journ. Bot., 1872, p. 356). It is to the different characters of the stations they occupy with respect to exposure, moisture, &c., that the variability observed in many types of lichens is to be attributed.

2. Distribution.—From what has now been said it will readily be inferred that the distribution of lichens over the surface of the globe is regulated, not only by the presence of suitable substrata, but more especially by climatic conditions. At the same time it may safely be affirmed that their geographical range is more extended than that of any other class of plants, occurring as they do in the coldest and warmest regions—the dry deadwoods of arctic and antarctic seas and in the torrid valleys of tropical climes, as well as on the greatest mountain elevations yet attained by man, on projecting rocks even far above the snow-line (e.g., Lecidea geographica, Lecidea articae). In fact, lichens have been found by far the largest portion of the vegetation, occurring everywhere on the ground and on rocks, and fruiting freely; while terrestrial species of Cladonia and Stereocaulon are seen in the greatest luxuriance and abundance spreading over extensive tracts almost to the entire exclusion of other vegetation. The lichen flora of temperate regions again is essentially distinguished from the preceding by the frequency of corticolous species belonging to Lecanora, Lecidea and Graphidiaceae. In intertropical regions lichens attain their maximum development (and beauty) in the foliaceous Sticieae and Parmeleae, while they are especially characterized by epiphyllous species, as Strigula, and by many peculiar cortieole Theleotrema, Graphideae and Pyrenorcarpi. Some lichens, especially saxicolous ones, seem to be cosmopolitan (e.g., Lecanora subulata, Cladonia pyxidata); and others, not strictly cosmopolitan, have been observed in regions widely apart. A considerable number of species are endemic, but further research will no doubt show that most of them occur in other climatic regions similar to those in which they have hitherto alone been detected. To give any detailed account, however, of the distribution of the different genera (not to speak of that of individual species) of lichens would necessarily far exceed available limits.

LICHFIELD—LICHENBERG, G. C.

Entwicklung einiger Flechtenapothecien (Flora, Bd. 88, 1901);
"Untersuchungen über die Entwicklungsgeschichte der Flechtenapo-
thecien," Bot. Zeit. (1904); O. V. Darbishire, "Über die Apo-
Jahrb. (Bd. 14, 1900). Chemistry—W. Zittel, "Geflechten-pro-
dukte," Beir. z. bot. Centralbl. (Bd. 14, 1903); Die Flechtenstoffe
(J. M. C.; V. H. B.).

LICHFIELD, a city, county of a city, and municipal borough in
the Lichfield parliamentary division of Staffordshire, England,
118 m. N.W. from London. Pop. (1901) 7902. The London
and North-Western railway has stations at Trent Valley Junction
on the main line, and in the city on a branch westward. The town
lies in a pleasant country, on a small stream draining eastward
to the Trent, with low hills to the E. and S. The cathedral is
small (the full internal length is only 370 ft., and the breadth of
the nave 68 ft.), but beautiful in both situation and style. It
stands near a picturesque sheet of water named Minster Pool.
The present building dates from various periods in the 13th and
14th centuries, but the various parts cannot be allocated to
fixed years, as the old archives were destroyed during the
Civil Wars of the 17th century. The earlier records of the church
are equally doubtful. A Saxon church founded by St Chad, who
was subsequently enshrined here, occupied the site from the
close of the 7th century; of its Norman successor portions of
the foundations have been excavated, but no record exists
either of its date or of its builders. The fine exterior of the
cathedral exhibits the feature, unique in England, of a lofty
central and two lesser western spires, of which the central,
352 ft. high, is a restoration attributed to Sir Christopher Wren
after its destruction during the Civil Wars. The west front is
composed of three stages of ornate arcading, with niches contain-
ing statues, of which most are modern. Within, the south
transept shows simple Early English work, the north transept
and chapter house more ornate work of a later period in that
style, the nave, with its geometrical ornament, marks the
transition to the Decorated style, while the Lady chapel is a
beautiful specimen of fully developed Decorated work with an
aisled east end. The west front probably falls in date between
the nave and the Lady chapel. Among numerous monuments
are—memorials to Samuel Johnson, a native of Lichfield, and
to David Garrick, who spent his early life and was educated here;
a monument to Major Hudson, who fell in the Indian mutiny,
and whose father was canon of Lichfield; the tomb of Bishop
Hacket, who restored the cathedral after the Civil Wars; and a
remarkable effigy of Perpendicular date displaying Sir John
Stanley stripped to the waist and awaiting chastisement. Here
is also the "Sleeping Children," a masterpiece by Chantrey (1817).
A picturesque bishop's palace (1625) and a theological college
(1824) are adjacent to the cathedral. The diocese covers the
greater part of Staffordshire and about half the parishes in
Shropshire, with small portions of Cheshire and Derbyshire.
The church of St Chad is ancient though extensively restored;
on its site St Chad is said to have occupied a hermit's cell. The
principal schools are those of King Edward and St Chad. There
are many picturesque half-timbered and other old houses, among
which is that in which Johnson was born, which stands in the
market-place, and is the property of the corporation and opened
to the public. There is also in the market place a statue to
Johnson. A fair is held annually on Whit-Monday, accompanied
by a pageant of ancient origin. Brewing is the principal industry,
and in the neighbourhood are large market gardens. The city
is governed by a mayor, 6 aldermen and 18 councillors. Area,
3473 acres.

There is a tradition that "Christianfield" near Lichfield was
the site of the martyrdom of a thousand Christians during the
persecutions of Maximian about 286, but there is no evidence in
support of the tradition. At Wall, 3 m. from the present city,
there was a Romano-British village called Letocetum ("grey
wood"), from which the first half of the name Lichfield is
derived. The first authentic notice of Lichfield (Lyceidfeldh,
Lyckfeld, Lichfeld) occurs in Bede's history where it is mentioned
as the place where St Chad fixed the episcopal see of the Mercians.
After the foundation of the see by St Chad in 669, it was raised in
1786 by Pope Adrian through the influence of Offa, King of
Mercia, to the dignity of an archbishopric, but in 803 the primacy
was restored to Canterbury. In 1075 the see of Lichfield
was removed to Chester, and thence a few years later to Coventry,
but it was restored in 1148. At the time of the Domesday Survey
Lichfield was held by the bishop of Chester: it is not
called a borough, and it was a small village, whence, on account
of its insignificance, the see had been moved. The lordship
and manor of the town were held by the bishop until the reign
of Edward VI., when they were leased to the corporation.
There is evidence that a castle existed here in the time of Bishop
Roger Clinton (temp. Henry I.), and a footpath near the grammar-
school retains the name of Castle-ditch. Richard II. gave
a charter (1387) for the foundation of the gild of St Mary and St
John the Baptist; this gild obtained the whole local government,
which it exercised until its dissolution by Edward VI.,
who incorporated the town (1548), vesting the government
in two bailiffs and twenty-four burgesses; further charters were
given by Mary, James I. and Charles II. (1664), the last, incorporating
it under the title of the "bailiffs and citizens of the city of Lich-
field," was the governing charter until 1835; under this charter
the governing body consisted of two bailiffs and twenty-four
burenh. Lichfield sent two members to the parliament of 1304
and to a few succeeding parliaments, but the representation
did not become regular until 1552; in 1807 it lost one member,
and in 1885 its representation was merged in that of the
county. By the charter of James I. the market day was changed
from Tuesday to Tuesday and Friday; the Tuesday market
disappeared during the 19th century; the only existing fair is a
small pleasure fair of ancient origin held on Ash-Wednesday;
the annual fête on Whit-Monday claims to date from the time
of Alfred. In the Civil Wars Lichfield was divided. The
cathedral authorities with certain following were for the
king, but the townsfolk generally sided with the parliament,
and this led to the fortification of the close in 1643. Lord Brooke,
notorious for his hostility to the church, came against it, but
was killed by a deflected bullet on St Chad's day, an accident
welcomed as a miracle by the Royalists. The close yielded
and was retaken by Prince Rupert in this year; but on the break-
down of the king's cause in 1646 it again surrendered.
The cathedral suffered terrible damage in these years.

See Rev. T. Harwood, Hist. and Antiquities of Church and City
of Lichfield (1866), Victoria County History, Stafford.

LICHTENBERG, Georg Christoph (1742-1799), German
physicist and satirical writer, was born at Oberramstadt,
Darmstadt, on the 1st of July 1742. In 1763 he entered Göttingen
university, where in 1769 he became extraordinary professor
of physics, and six years later ordinary professor. This post he
held till his death on the 24th of February 1799. As a physicist
he is best known for his investigations in electricity, more especially as to the so-called Lichtenberg figures, which are fully described in his memoirs *Super nova methodo motum ac naturam fluidi electrici investigavit* (Göttingen, 1777–1780). These figures, originally studied on account of the light they were supposed to throw on the nature of the electric fluid or fluids, have reference to the distribution of electricity over the surface of non-conductors. They are produced as follows: A sharp-pointed needle is placed perpendicular to a non-conducting plate, such as of resin, ebonite or glass, with its point very near to or in contact with the plate, and a Leyden jar is discharged into the needle. The electrification of the plate is now tested by sitting over it a mixture of flowers of sulphur and red lead. The negatively electrified sulphur is seen to attach itself to the positively electrified parts of the plate, and the positively electrified red lead to the negatively electrified parts. In addition to the distribution of colour thereby produced, there is a marked difference in the form of the figure, according to the nature of the electricity originally communicated to the plate. If it be positive, a widely extending patch is seen on the plate, consisting of a dense nucleus, from which branches radiate in all directions; if negative the patch is much smaller and has a sharp circular boundary entirely devoid of branches. If the plate receives only a small charge, as, for example, from a partly charged coil, “mixed” figures result; consisting of a large red central nucleus, corresponding to the negative charge, surrounded by yellow rays, corresponding to the positive charge. The difference between the positive and negative figures seems to depend on the presence of the air; for the difference tends to disappear when the experiment is conducted in vacuo. Riess explains it by the negative electrification of the plate caused by the friction of the water vapour, &c., driven along the surface by the explosion which accompanies the disruptive discharge at the point. This electrification would favour the spread of a positive, but hinder that of a negative discharge. There is, in all probability, a connexion between this phenomenon and the peculiarities of positive and negative brush and other discharge in air.

As a satirist and humorist Lichtenberg takes high rank among the German writers of the 18th century. His biting wit involved him in many controversies with well-known contemporaries, such as Lavater, whose science of physiognomy he ridiculed, and Voss, whose views on Greek pronunciation called forth a powerful reply in *Über die Sprachverwandtschaft der Griechen- und Römersprache* (Gottingen, 1782). In 1769 and again in 1774 he resided for some time in England and his Briefe aus England (1776–1778), with admirable descriptions of Garrick’s acting, are the most attractive of his writings. He contributed to the *Göttinische Taschenkalender* from 1778 onwards, and to the *Göttinische Magazin der Literatur und Wissenschaft*, which he edited for three years (1780–1782) with J. C. A. Forster. He also published in 1704–1709 an *Ausführliche Erklärung der Hofgärtischen Küstchenstücke*.

**Lichtenberg**, formerly a small German principality on the west bank of the Rhine, enclosed by the Nahe, the Biers and the Glan, now belonging to the government district of Trier, Prussian Rhine province. The principality was constructed of parts of the electorate of Trier, of Nassau-Saarbrücken and other districts, and lay between Rhenish Bavaria and the old Prussian province of the Rhine. Originally called the lordship of Baumholder, it owed the name of Lichtenberg and its elevation in 1810 to a principality to Ernest, duke of Saxe-Coburg, to whom it was ceded by Prussia, in 1816, in accordance with terms agreed upon at the congress of Vienna. The duke, however, restored it to Prussia in 1834, in return for an annual pension of £12,000 sterling. The area is about 210 sq. m.

**LICINIUS, GRANIUS**, Roman annalist, probably lived in the age of the Antonines (2nd century A.D.). He was the author of a brief epitome of Roman history based upon Livy, which he utilized as a means of displaying his antiquarian lore. Accounts of omens, portents, prodigies and other remarkable things apparently took up a considerable portion of the work. Some fragments of the book remaining relate to the years 163–178 B.C. are preserved in a British Museum MS.

Editions.—C. A. Pertz (1857); seven Bonn students (1858); M. Füllmisch (1904); see also J. N. Madvig, *Kleine philologische Schriften* (1875), and the list of articles in periodicals in Füllmisch’s edition (p. iv.).

**LICINIUS** [Flavius Galerius Valerius Licinius], Roman emperor, A.D. 307–324, of Illyrian peasant origin, was born probably about 230. After the death of Flavius Valerius Severus he was elevated to the rank of Augustus by Galerius, his former friend and companion in arms, on the 11th of November 307, receiving as his immediate command the provinces of Illyricum. On the death of Galerius, in May 311, he shared the entire empire with Maximinus, the Hellespont and the Thracian Bosporus being the dividing line. In March 313 he married Constantia, half-sister of Constantine, at Mediolanum (Milan), in the following month inflicted a decisive defeat on Maximinus at Heraclea Pontica, and established himself master of the East, while his brother-in-law, Constantine, was supreme in the West. In 314 his jealousy led him to encourage a treasonable enterprise on the part of Bassianus against Constantine. When his perfidy became known a civil war ensued, in which he was defeated at Nicopolis in Ciliciae in Pannonia (October 8th, 314), and next in the plain of Mardia in Thrace; the outward reconciliation, which was effected in the following December, left Licinius in possession of Thrace, Asia Minor, Syria and Egypt, but added numerous provinces to the Western empire. In 323 Constantine, tempted by the “advanced age and unpopular vices” of his colleague, again declared war against him, and, having defeated his army at Adrianople (3rd of July 323), succeeded in shutting him up within the walls of Byzantium. The defeat of the superior fleet of Licinius by Flavius Julius Crispus, Constantine’s eldest son, compelled his withdrawal to Bithynia, where a last stand was made; the battle of Chrysopolis, near Chalcedon (18th of September), finally resulted in his submission. He was interned at Thessalonica and executed in the following year on a charge of treasonable correspondence with the barbarians.

See also *Orosius*, lib. vii. 28.; *Zonaras*, 1.; *Victor*, *Caes.*, 40. 41.; *Eutropius*, xi. 3.; *Orosius*, vii. 28.

**LICINIUS CALVUS STOLO, GAIUS**, Roman statesman, the chief representative of the plebeian Licinian gens, was tribune in 377 B.C., consul in 361. His name is associated with the Licinian or Licinio-Sextian laws (proposed 377, passed 357), which practically ended the struggle between patricians and plebeians. He was himself fined for possessing a larger share of the public land than his own law allowed. See also *Rome: History*, II. “The Republic.”

**LICINIUS MACER CALVUS, GAIUS** (82–47 B.C.), Roman poet and orator, was the son of the annalist Licinius Macer. As a poet he is associated with his friend Catullus, whom he followed in style and choice of subjects. As an orator he was the leader of the opponents of the florid Asiatic school, who took the simplest Attic orators as their model and attacked even Cicero as wordy and artificial. Calvus held a correspondence on questions connected with rhetoric, perhaps (if the reading be correct) the *commentarii* alluded to by Tacitus (*Dialogus*, 23); compare also Cicero, *Ad Fam.*, xv. 21). Twenty-one speeches by him are mentioned, amongst which the most famous were those delivered against Publius Vatinius. Calvus was very short of stature, and is alluded to by Catullus (Ode 53) as *Sala-pum discertum* (eloquent Lilliputian).

For Cicero’s opinion see *Brutus*, 82; *Quintilian*, x. 1. 115; *Tacticus*, *Dialogus*, 18. 21; the monograph by F. Plesius (Paris, 1896) contains a collection of the fragments (verse and prose).
LICODIA, a town of Sicily in the province of Catania, 4 m. W. of Vizzini, which is 30 m. S.W. of Catania by rail. Pop. (1901) 7032. The name Eubea was given to the place in 1872 owing to a false identification with the Greek city of Euboea, a colony of Leontini, founded probably early in the 6th century B.C. and taken by Gelon. The town occupies the site of an unknown Sice city, the cemeteries of which have been explored. A few vases of the first period were found, but practically all the tombs explored in 1808 belonged to the fourth period (700–500 B.C.) and show the gradual process of Hellenization among the Sicels.

See Römische Mitteilungen, 1898, 305 seq.; Notizie degli scavi, 1902, 219. (T. A.)

LICTORS (lictores), in Roman antiquities, a class of the attendants (appendiores) upon certain Roman and provincial magistrates.1 As an institution (supposed by some to have been borrowed from Etruria) they went back to the regal period and continued to exist till imperial times. The majority of the city lictors were freedmen; they formed a corporation divided into decuriae, from which the lictors of the magistrates in office were drawn. No officials had the nomination of their own. In Rome they wore the toga, perhaps girded up; on a campaign and at the celebration of a triumph, the red military cloak (sagum); at funerals, black. As representatives of magistrates who possessed the imperium, they carried the fasces and axes in front of them (see Fasces). They were exempt from military service; received a fixed salary; theoretically they were nominated for a year, but really for life. They were the constant attendants, both in and out of the house, of the magistrate to whom they were attached. They walked before him in Indian file, cleared a passage for him (summovebant) through the crowd, and saw that he was received with the marks of respect due to his rank. They stood by him when he took his seat on the tribunal; mounted guard before his house, against the wall of which they stood the fasces; summoned offenders before him, seized, bound and scourged them, and (in earlier times) carried out the death sentence. It should be noted that directly a magistrate entered an allied, independent state, he was obliged to dispense with his lictors. The king had twelve lictors; each of the consuls (immediately after their institution) twelve, subsequently limited to the monthly officiating consul, although Caesar appears to have restored the original arrangement; the dictator, as representing both consuls, twenty-four; the emperors twelve, until the time of Domitian, who had twenty-four. The Flamen Dialis, each of the Vestals, the magister vicorum (overseer of the sections into which the city was divided) were also accompanied by lictors. These lictors were probably supplied from the lictores curiati, thirty in number, whose functions were specially religious, one of them being in attendance on the pontifex maximus. They originally summoned the comitia curiata, and when its meetings became merely a formality, acted as the representatives of that assembly. Lictors were also assigned to private individuals at the celebration of funeral games and to the agilis at the games provided by them and the theatrical representations under their supervision.

For the fullest account of the lictors, see Mommsen, Römisches Staatsrecht, i. 355, 374 (3rd ed., 1887).

LIDDELL, HENRY GEORGE (1811–1898), English scholar and divine, eldest son of the Rev. Henry George Liddell, younger brother of the first Baron Ravensworth, was born at Winchester, near Bishop Auckland, on the 6th of February 1811. He was educated at Charterhouse and Christ Church, Oxford. Gaining a double first in 1833, Liddell became a college tutor, and was ordained in 1838. In the same year Dean Gaisford appointed him Greek reader in Christ Church, and in 1840 he was appointed to the headmastership of Westminster School. Meanwhile his life work, the great Lexicon (based on the German work of F. Passow), which he and Robert Scott began as early as 1834, had made good progress, and the first edition appeared in 1833. It immediately became the standard Greek-English dictionary and still maintains this rank, although, notwithstanding the great additions made of late to our Greek vocabulary from inscriptions, papyri and other sources, scarcely any enlargement has been made since about 1880. The 8th edition was published in 1897. As headmaster of Westminster Liddell enjoyed a period of great success, followed by trouble due to the outbreak of fever and cholera in the school. In 1855 he accepted the deanship of Christ Church, then vacant by the death of Gaisford. In the same year he brought out a History of Ancient Rome (much used in an abridged form as the Student's History of Rome) and took a very active part in the first Oxford University Commission. His tall figure, fine presence and aristocratic mien were for many years associated with all that was characteristic of Oxford life. Coming just at the transition period when the "old Christ Church," where Pusey strove so hard to preserve, was inevitably becoming broader and more liberal, it was chiefly due to Liddell that necessary changes were effected with the minimum of friction. In 1859 Liddell welcomed the then prince of Wales when he matriculated at Christ Church, being the first holder of that title who had matriculated since Henry V. In conjunction with Sir Henry Acland, Liddell did much to encourage the study of art at Oxford, and his taste and judgment gained him the admiration and friendship of Ruskin. In 1891, owing to advancing years, he resigned the deanship. The last years of his life were spent at Ascot, where he died on the 18th of January 1898. Dean Liddell married in July 1846 Miss Lorina Reeve (d. 1910), by whom he had a numerous family.

See memoir by H. L. Thompson, Henry George Liddell (1899).

LIDDESDALE, the valley of Liddel Water, Roxburghshire, Scotland, extending in a south-westerly direction from the vicinity of Peel Fell to the Esk, a distance of 21 m. The Waverley route of the North British railway runs down the dale, and the Cattrall, or Picts' Dyke, crosses its head. At one period the points of advantage on the river and its affluents were occupied with freestones and peat-tops, but many of them have disappeared and the remainder are in decay. Larriston Tower belonged to the Elliotts, Mangerton to the Armstrongs and Park to "little Jack Elliot," the outlaw who nearly killed Bothwell in an encounter in 1566. The chief point of interest in the valley, however, is Hermitage Castle, a vast, massive H-shaped fortress of enormous strength, one of the oldest baronial buildings in Scotland. It stands on a hill overlooking Hermitage Water, a tributary of the Liddel. It was built in 1244 by Nicholas de Souls and was captured by the English in David II.'s reign. It was retaken by Sir William Douglas, who received a grant of it from the king. In 1492 Archibald Douglas, 5th earl of Angus, exchanged it for Bothwell Castle on the Clyde with Patrick Hepburn, 1st earl of Bothwell. It finally passed to the duke of Buccleuch, under whose care further ruin has been arrested. It was here that Sir Alexander Ramsay of Dalhousie was received by Sir William Douglas in 1542, and that James Hepburn, 4th earl of Bothwell, was visited by Mary, queen of Scots, after the assault referred to.

To the east of the castle is Ninestane Rig, a hill 943 ft. high, 4 m. long and 1 m. broad, where it is said that William de Soule, hated for oppression and cruelty, was (in 1320) boiled by his own vassals in a copper cauldron, which was supported on two of the nine stones which composed the "Druidical circle" that gave the ridge its name. On one of these stones (1802 ft.), the writer of ballads, who was born in the parish of Southdean (pronounced Soudan), was for several years schoolmaster of Soughtree, near the head of the valley. The castle of the lairds of Liddesdale stood near the river Hermitage Water and the Liddel and around it grew up the village of Castleton.

LIDDON, HENRY PARRY (1829–1890), English divine, was the son of a naval captain and was born at North Stoneham, Hampshire, on the 20th of August 1829. He was educated at King's College School, London, and at Christ Church, Oxford,
where he graduated, taking a second class, in 1850. As vice-principal of the theological college at Cuddesdon (1854–1859) he wielded considerable influence, and, on returning to Oxford as vice-principal of St Edmund's Hall, became a growing force among the undergraduates, exercising his influence in strong opposition to the liberal reaction against Tractarianism, which had set in after Newman's secession in 1845. In 1864 the bishop of Salisbury (W. K. Hamilton), whose examining chaplain he had been, appointed him prebendary of Salisbury cathedral. In 1866 he delivered his Bampton Lectures on the doctrine of the divinity of Christ. From that time his fame as a preacher, which had been steadily growing, may be considered established.

In 1870 he was made canon of St Paul's Cathedral, London. He had before this published Some Words for God, in which, with great power and eloquence, he combated the scepticism of the day. His preaching at St Paul's soon attracted vast crowds. The afternoon sermon, which fell to the lot of the canon in residence, had usually been delivered in the choir, but soon after Liddon's appointment it became necessary to preach the sermon under the dome, where from 3000 to 4000 persons used to gather to hear the preacher. Few orators belonging to the Church of England have acquired so great a reputation as Liddon. Others may have surpassed him in originality, learning or reasoning power, but for grasp of his subject, clearness of language, lucidity of arrangement, felicity of illustration, vividness of imagination, elegance of diction, and above all, for sympathy with the intellectual position of those whom he addressed, he has hardly been rivalled. In the elaborate arrangement of his matter he is thought to have imitated the great French preachers of the age of Louis XIV.

In 1870 he also made Irish professor of exegesis at Oxford. The combination of the two appointments gave him extensive influence over the Church of England. With Dean Church he may be said to have restored the waning influence of the Tractarian school, and he succeeded in popularizing the opinions held by the late Pusey and Keble, had been more widely known. His forceful style was equally conspicuous in his opposition to the Church Discipline Act of 1874, and in his denunciation of the Bulgarian atrocities of 1876. In 1882 he resigned his professorship and utilized his thus increased leisure by travelling in Palestine and Egypt, and showed his interest in the Old Catholic movement by visiting Döllinger at Munich. In 1886 he became chancellor of St Paul's, and it is said that he declined more than one offer of a bishopric. He died on the 9th of September 1890, in the full vigour of his intellect and at the zenith of his reputation. He had undertaken and nearly completed an elaborate life of Dr Pusey, for whom his admiration was unabated; and this work was completed after his death by Messrs Johnston and Wilson. Liddon's great influence during his life was due to his personal fascination and the beauty of his pulpit oratory rather than to any high qualities of intellect. As a theologian his outlook was that of the 16th rather than the 17th century; and, as a preacher, Liddon's Lectures are difficult to realize how they can ever have been hailed as a great contribution to Christian apologetics. To the last he maintained the narrow standpoint of Pusey and Keble, in defiance of all the developments of modern thought and modern scholarship; and his latter years were embittered by the consciousness that the younger generation of the disciples of his school were beginning to make friends of the Mammon of scientific unrighteousness.

The publication in 1889 of Lux Mundi, a series of essays attempting to harmonize Anglican Catholic doctrine with modern thought, was a severe blow to him, for it showed that even at the Pusey House, established as the citadel of Puseyism at Oxford, the principles of Pusey were being departed from. Liddon's importance is now mainly historical. He was the last of the classical pulpit orators of the English Church, the last great popular exponent of the traditional Anglican orthodoxy. Besides the works mentioned, Liddon published several volumes of Sermons, a volume of Lent lectures entitled Some Elements of Religion (1870), and a collection of Essays and Addresses on such themes as Buddhism, Dante, &c.

See Life and Letters, by J. O. Johnston (1904); G. W. E. Russell, H. P. Liddon (1903); A. B. Donaldson, Five Great Oxford Leaders (1900), from which the life of Liddon was reprinted separately in 1905.

LIE, JONAS LAURITZ EDEMIL (1833–1908), Norwegian novelist, was born on the 6th of November 1833 close to Housund (Eker), near Drammen. In 1878, his father being appointed sheriff of Tromsö, the family removed to that Arctic town. Here the future novelist enjoyed an untrammelled childhood among the shipping of the little Nordland capital, and gained acquaintance with the wild seafaring life which he was afterwards to describe. In 1846 he was sent to the naval school at Frederiksværn, but his extreme near-sight unhitted him for the service, and he was transferred to the Latin school at Bergen. In 1851 he went to the university of Christiania, where Ibsen and Björnson were among his fellow-students. Jonas Lie, however, showed at this time no inclination to literature. He pursued his studies as a lawyer, took his degrees in law in 1858, and settled down to practice as a solicitor in the little town of Kongsvinger. In 1860 he married his cousin, Thomasine Lie, whose collaboration in his work he acknowledged in 1893 in a graceful article in the Samtiden entitled "Min hustru." In 1866 he published his first book, a volume of poems. He made unlucky speculations in wood, and the consequent financial embarrassment induced him to return to Christiania to try his luck as a man of letters. As a journalist he had no success, but in 1870 he published a melancholy little romance, Den Prestes Ying (Eng. trans., The Visionary, 1894), which made him famous. Lie proceeded to Rome, and published Tales in 1871 and Tre masteren "Fremiden" (Eng. trans., The Barque "Future," Chicago, 1879), a novel, in 1872. His first great book, however, was Lodsen og hans Hustru (The Pilot and His Wife, 1874), which placed him at the head of Norwegian novelists; it was written in the little town of Rœca di Papa in the Albano mountains. From that time Lie enjoyed, with Björnson and Ibsen, a stipend as poet from the Norwegian government. Lie spent a few years partly in Dresden, partly in Stuttgart, with frequent summer excursions to Berchtesgaden in the Bavarian highlands. During his exile he produced the drama in verse called Faustina Strøm (1876). Returning to Norway, Lie began a series of romances of modern life in Christiania, of which Thomas Ross (1878) and Adam Schrader (1879) were the earliest. He returned to Germany, and settled first in Dresden again, then in Hamburg, but not to 1882, when he took up his abode in Paris, where he lived in close retirement in the society of Scandinavian friends. His summers were spent at Berchtesgaden in Tirol. The novels of his German period are Rülland (1881) and Gaa paa ("Go Ahead!" 1882), tales of life in the Norwegian merchant navy. His subsequent works, produced with great regularity, enjoyed an immense reputation in Norway. Among the best of them are: Løvevæver (1883, Eng. trans., Life's Wove, 1886); Familien paa Gåeboden ("The Family on the Island," 1881); M. Bias (1885), describing the gradual ruin of a Norwegian family; Et Samliv ("Life in Common," 1887), describing a marriage of convenience. Two of the most successful of his novels were The Commodore's Daughters (1886) and Niobe (1894), both of which were presented to English readers in the International library, edited by M. Gosse. In 1891–1892 he wrote, under the influence of the new romantic impulse, twenty-four folk-tales, printed in two volumes entitled Trold. Some of these were translated by R. N. Bain in Weird Tales (1893), illustrated by L. Housman. Among his later works were the romance Naar Sol gaaer ned ("When the Sun goes down," 1895), the powerful novel of Dyre Rein (1896), the fairy drama of Lindelin (1897), Pasto Forland (1898), a romance which contains much which is autobiographical, When the Iron Curtain Falls (1901), and The Consul (1904). His Somaland Værker were published at Copenhagen in 14 vols. (1902–1904). Jonas Lie left Paris in 1897, and, after spending a year in Rome, returned to Norway, establishing himself at Holksøen, near Christiansand. He died at Christiania on the 5th of July 1908. As a novelist he stands 'with those minute and unobtrusive
painters of contemporary manners who defy arrangement in this or that school. He is with Mrs Gaskell or Ferdinand Fabre; he is not entirely without relation with that old-fashioned favourite of the public, Fredrika Bremer.

His son, Erik Lie (b. 1868), published a successful volume of stories, Med Blyanter, in 1890; and is also the author of various works on literary history. An older son, Mons Lie (b. 1864), studied the violin in Paris, but turned to literature in 1894. Among his works are the plays Krægeden (1897); Lombardo og Agrippina (1889); Don Juan (1900); and the novels, Sjøfaren (1901); Adam, Kæm (1903) and J. Kjædensmel (1904). (E. G.)

LIE, MARIUS SOPHUS (1842–1899), Norwegian mathematician, was born at Nordfjordeid, near Bergen, on the 17th of December 1842, and was educated at the university of Christiania, where he took his doctor's degree in 1868 and became extraordinary professor of mathematics (a chair created specially for him) four years later. In 1886 he was chosen to succeed Felix Klein in the chair of geometry at Leipzig, but as his fame grew a special post was arranged for him in Christiania. But his health was broken down by too assiduous study, and he died at Christiania on the 18th of February 1890, six months after his return. Lie's work exercised a great influence on the progress of mathematical science during the later decades of the 19th century. His primary aim has been declared to be the advance and elaboration of the theory of differential equations, and it was with this end in view that he developed his theory of transformation groups, set forth in his Theorie der Transformationsgruppen (3 vols., Leipzig, 1888–1893), a work of wide range and great originality, by which probably his name is best known. A special application of his theory of continuous groups was to the general problem of non-Euclidean geometry. The last part of the book above mentioned was devoted to a study of the foundations of geometry, considered from the standpoint of B. Riemann and H. von Helmholtz; and he intended to publish a systematic exposition of his geometrical investigations, in conjunction with Dr G. Scheffers, but only one volume made its appearance (Geometrie der Berührungs- transformationen, Leipzig, 1896). Lie was a foreign member of the Royal Society, as well as an honorary member of the Cambridge Philosophical Society and the London Mathematical Society, and his geometrical inquiries gained him the much-coveted honour of the Lobatchewsky prize.

An analysis of Lie's works is given in the Bibliotheca Mathematica (Leipzig, 1900–1902).

LIEBER, FRANCIS (1800–1872), German-American publicist, was born at Hanover, Westphalia, on the 18th of March 1800. He served with his two brothers under Blücher in the campaign of 1815, fighting at Ligny, Waterloo and Namur, where he was twice dangerously wounded. Shortly afterwards he was arrested for his political sentiments, the chief evidence against him being several songs of liberty which he had written. After several months he was discharged without a trial, but was forbidden to pursue his studies at the Prussian universities. He accordingly went to Jena, where he took his degrees in 1820, continuing his studies at Halle and Dresden. He subsequently took part in the Greek War of Independence, publishing his experiences in his Journal in Greece (Leipzig, 1823; and under the title The German Anarchists, Amsterdam, 1823). For a year he was in Rome as tutor to the son of the historian Niebuhr, then Prussian ambassador. Returning to Berlin in 1825, he was imprisoned at Koepenick, but was released after some months through the influence of Niebuhr. In 1827 he went to the United States and as soon as possible was naturalized as a citizen. He settled at Boston, and for five years edited The Encyclopaedia Americana (13 vols.). From 1835 to 1856 he was professor of history and political economy in South Carolina College at Columbia, S.C., and during this period wrote his three chief works, Manual of Political Ethics (1838), Legal and Political Hermeneutics (1839), and Civil Liberty and Self Government (1853). In 1856 he resigned and next year was elected to a similar post in Columbia College, New York, and in 1865 became professor of constitutional history and public law in the same institution. During the Civil War Lieber rendered services of great value to the government. He was one of the first to point out the madness of secession, and was active in upholding the Union. He prepared, upon the requisition of the president, the important Code of War for the Government of the Armies of the United States in the Field, which was promulgated by the Government in General Orders No. 100 of the war department. This code suggested to Bluntschi his codification of the law of nations, as may be seen in the preface to his Droit International Codifié. During this period also Lieber wrote his Guerrilla Parties with Reference to the Laws and Usages of War. At the time of his death he was the umpire of the commission for the adjudication of Mexican claims. He died on the 2nd of October 1872. His books were acquired by the University of California, and his papers were placed in the Johns Hopkins University.

LIEBRECHT, MAX (1849–1900), German painter and etcher, was born in Berlin. After studying under Steffelck, he entered the school of art at Weimar in 1860. Though the straightforward simplicity of his first exhibited picture, “Women plucking Geese,” in 1872, presented already a striking contrast to the conventional art then in vogue, it was heavy and bituminous in colour, like all the artist’s paintings before his visit to Paris at the end of 1872. A summer spent at Barbizon in 1873, where he became personally acquainted with Millet and had occasion to study the works of Corot, Troyon, and Daubigny, resulted in the clearing and brightening of his palette, and taught him to forget the example of Munkacsy, under whose influence he had produced his first pictures in Paris. He subsequently went to Holland, where the example of Israels confirmed him in the method he had adopted at Barbizon; but on his return to Munich in 1878 he caused much unfavourable criticism by his realistic painting of “Christ in the Temple,” which was condemned by the clergy as irreverent and retained his only attempt at a scriptural subject. Henceforth he devoted himself exclusively to the study of free-light and to the painting of the life of humble folk. He found his best subjects in the orphanages and asylums for the old in Amsterdam, among the peasants in the fields and village streets of Holland, and in the beer-gardens, factories, and workrooms of his own country. Germany was reluctant, however, in admitting the merit of an artist whose style and method were so markedly at variance with the time-honoured academic tradition. Only when his fame had become international was Holland reconciled to his ideas; his compatriots realize the eminent position which is his due in the history of German art. It is hardly too much to say that Liebermann has done for his country what Millet did for France. His pictures hold the fragrance of the soil and the breezes of the heavens. His people move in their proper atmosphere, and their life is stated in all its monotonous simplicity, without artificial pathos or melodramatic exaggeration. His first success was a medal awarded him for “An Asylum for Old Men” at the 1881 Salon. In 1884 he settled again in Berlin, where he became professor of the Academy in 1898. He became a member of the Société nationale des Beaux Arts, of the Société royale belge des Aquarellistes, and of the Cercle des Aquarellistes at the Hague. Liebermann is represented in most of the German and other continental galleries. The Berlin National Gallery owns “The Flax-Spinners”; the Munich Pinakothek, “The Woman with Goats”; the Hamburg Gallery, “The Net-Menders”; the Hanover Gallery, the “Village Street in Holland”; “The Steamstress” is at the Dresden Gallery; the “Man on the Dunes” at Leipzig; “Dutch Orphan Girls” at Strassburg; “Beer-cellar at Brandenburg” at the Luxembourg Museum in Paris, and the “Knobplerinnen” in Venice. His etchings are to be found in the leading print cabinets of Europe.

LIEBIG, JUSTUS VON, BARON (1803–1873), German chemist, was born at Darmstadt, according to his baptismal certificate, on the 12th of May 1803 (4th of May, according to his mother). His father, a drysalter and dealer in colours, used sometimes to
make experiments in the hope of finding improved processes for the production of his wares, and thus his son early acquired familiarity with practical chemistry. For the theoretical side he read all the text-books which he could find, somewhat to the detriment of his ordinary school studies. Having determined to make chemistry his profession, at the age of fifteen he entered the shop of an apothecary at Appenheim, near Darmstadt; but he soon found how great is the difference between practical pharmacy and scientific chemistry, and the explosions and other incidents that accompanied his private efforts to increase his chemical knowledge disposed his master to view without regret his departure at the end of ten months. He next entered the university of Bonn, but migrated to Erlangen when the professor of chemistry, K. W. G. Kastner (1753-1857), was appointed in 1821 to the chair of physics and chemistry at the latter university. He followed this professor to learn how to analyse certain minerals, but in the end he found that the teacher himself was ignorant of the art. Indeed, as he himself said afterwards, it was a wretched time for chemistry in Germany. No laboratories were accessible to ordinary students, who had to content themselves with what the universities could give in the lecture-room and the library, and though both at Bonn and Erlangen Liebig endeavoured to make up for the deficiencies of the official instruction by founding a students' physical and chemical society for the discussion of new discoveries and speculations, he felt that he could never become a chemist in his own country. Therefore, having graduated as Ph.D. in 1822, he left Erlangen—where he subsequently complained that the contang of the "greatest philosopher and metaphysician of the century" (Schelling), in a period rich in words and ideas, but poor in true knowledge and genuine studies, 1 had cost him two precious years of his life—and by the liberality of Louis I., grand-duke of Hesse-Darmstadt, was enabled to go to Paris. By the help of L. J. Thénard he gained admission to the private laboratory of Dumas in the rue St. Jacques, and afterwards to the laboratories of chemistry and pharmacy at the École de Pharmacie, and soon afterwards, by the influence of A. von Humboldt, to that of Gay-Lussac, where in 1824 he concluded his investigations on the composition of the fulminates. It was on Humboldt's advice that he determined to become a teacher of chemistry, but difficulties stood in his way. As a native of Hesse-Darmstadt he ought, according to the academical rules of the time, to have studied and graduated at the university of Giessen, and it was only through the influence of Humboldt that the authorities forgave him for straying to the foreign university of Erlangen. After examination his Erlangen degree was recognized, and in 1824 he was appointed extraordinary professor of chemistry at Giessen, becoming ordinary professor two years later. In this small town his important work was accomplished. His first care was to persuade the Darmstadt government to provide a chemical laboratory in which the students might carry out experiments. Thus was founded the only laboratory, unique of its kind at the time, in conjunction with Liebig's unrivalled gifts as a teacher, soon rendered Giessen the most famous chemical school in the world; men flocked from every country to enjoy its advantages, and many of the most accomplished chemists of the 19th century had to thank it for their early training. Further, it gave a great impetus to the progress of chemical education throughout Germany, for the continued admonitions of Liebig combined with the influence of his pupils induced many other universities to build laboratories modelled on the same plan. He remained at Giessen for twenty-eight years, until in 1852 he accepted the invitation of the Bavarian government to the ordinary chair of chemistry at Munich university and this office he held, although he was offered the chair at Berlin in 1865, until his death, which occurred at Munich on the 10th of April 1853.

Apart from Liebig's labours for the improvement of chemical teaching, the influence of his experimental researches and of his contributions to chemical thought was felt in every branch of the science. In regard to methods and apparatus, mention should be made of his improvements in the technique of organic analysis, his plan for determining the natural alkalis and for ascertaining the molecular weights of organic bases by means of their chloro-platinates, his process for determining the quantity of urea in a solution—the first step towards the introduction of precise chemical methods into practical medicine—and his invention of the simple form of condenser known in every laboratory. His contributions to inorganic chemistry were numerous, including investigations on the elements found in coal tar, such as carbon, silicon, &c., on the separation of nickel and cobalt, and on the chemistry of phosphorus; but they are outweighed in importance by his work on organic substances. In this domain his first research was on the fulminates of mercuric silver, and his study of these bodies led him to the discovery of the aldehydes and zinsmaurs. The composition of fulminic acid as found by him was the same as that of cyanic acid, as found by F. Wöhler, and it became necessary to admit to them to be two bodies which differed in properties, though of the same chemical composition. The fulminates were the first examples of the many natural substances which he and his pupils showed to be the composition of organic acids, and in some cases, like fulminic acid, the element of one of the most important of all the organic acids. This discovery led directly to Wöhler's investigations on the formation of organic compounds from mineral substances, and to the establishment of the doctrine of the chemical theory of organic compounds, which, though still the subject of bitter opposition, is the foundation of modern organic chemistry.

These and other studies in pure chemistry mainly occupied his attention until about 1838, but the last thirty-five years of his life were devoted more particularly to the chemistry of the processes of life, both animal and vegetable. In animal physiology he set himself to prove that the chemistry of life was a branch of experimental biology, and he regarded all the chemical laws in the maintenance of life and health. To this end he examined such immediate vital products as blood, bile and urine; he analysed the juices of flesh, establishing the composition of creatin and inulin and the process of its degradation; he determined the nature of the uric acid and its derivatives; he investigated the formation and function of the body's gums and other substances; he showed how the process of combustion and oxidation performed within the organism. A secondary result of this line of study was the preparation of his food for infants and of his extract of meat. Vegetable physiology he pursued with special reference to agriculture, which he held to be the foundation of all trade and industry, but which could not be rationally practised without the guidance of chemical principles. His first publication on this subject was Die Chemie der Nahrung- und Ernährungsvorrichtungen, published in 1838, which was translated into English by Lyon Playfair. Rejecting the old notion that plants derive their nourishment from humus, he taught that they get carbon and nitrogen from the carbon dioxide and ammonia present in the atmosphere, and that the earth supplies them with these substances by the processes of photosynthesis and fixation which latter he regarded as essentially chemical in nature—while they obtain a small quantity of ammonium salts, because he held that the air does not supply ammonium salts in sufficient quantities to feed the organism's growth. On this theory he prepared artificial manures containing the essential mineral substances together with a small quantity of ammonium salts, because he held that the air does not supply ammonium salts in sufficient quantities to feed the organism's growth and development. He published experiments on ten acres of poor sandy land which he obtained from the town of Giessen in 1845. But in practice the results were not wholly satisfactory, and it was a long time before he recognized one important reason for the failure in the fact that

Bismarck's influence. There is no more curious episode in German history than the success with which Bismarck acquired the services of many of the men of 1848; but Liebknecht remained faithful to his principles and resigned his editorship. He became a member of the Arbeiterverein, and after the death of Ferdinand Lassalle he was the chief mouthpiece in Germany of Karl Marx, and was instrumental in spreading the influence of the newly-founded International. Expelled from Prussia in 1865, he settled at Leipzig, and it is primarily to his activity in Saxon among the newly-formed unions of workers that the modern social democratic party owes its origin. Here he conducted the Demokratisches Wochenblatt. In 1867 he was elected a member of the North German Reichstag, but in opposition to Lassalle's followers he refused all compromise with the 'capitalists,' and avowedly used his position merely for purposes of agitation whilst taking every opportunity for making the parliament ridiculous. He was strongly influenced by the 'great German' traditions of the democrats of 1848, and, violently anti-Prussian, he distinguished himself by his attacks on the policy of 1866 and the 'revolution from above,' and by his opposition to every form of militarism. His adherence to the traditions of 1848 are also seen in his dread of Russia, which he maintained to his death. His opposition to the war of 1870 exposed him to insults and violence, and in 1872 he was condemned to two years' imprisonment in a fortress for treasonable intentions. The union of the German Socialists in 1874 at the congress of Gotha was really a triumph of his influence, and from that time he was regarded as founder and leader of the party. From 1874 till his death he was a member of the German Reichstag, and for many years also of the Saxon diet. He was one of the chief spokesmen of the party, and he took a very important part in directing its policy. In 1881 he was expelled from Leipzig, but took up his residence in a neighbouring village. After the lapse of the Socialist law (1890) he became chief editor of the Vorwärts, and settled in Berlin. If he did not always find it easy in his later years to follow the new developments, he preserved to his death the idealism of his youth, the hatred both of Liberalism and of State Socialism; and though he was to some extent overshadowed by Bebel's greater oratorical power, he was the chief support of the orthodox Marxist tradition.

LIEBKNECHT, WILHELM (1826-1900), German socialist, was born at Giessen on the 29th of March 1826. Left an orphan at an early age, he was educated at the gymnasium in his native town, and attended the universities of Giessen, Bonn and Marburg. Before he left school he had become affected by the political discontent then general in Germany; he had already studied the writings of St Simon, from which he gained his first interest in communism, and had been converted to the extreme republican theories of which Giessen was a centre. He soon came into conflict with the authorities, and was expelled from Berlin apparently in consequence of the strong sympathy he displayed for some Poles, who were being tried for high treason. He proposed in 1846 to migrate to America, but went instead to Sardinia, where he earned his living as a teacher. As soon as the revolution of 1848 broke out he hastened to Paris, but the attempt to organize a republican corps for the invasion of Germany was prevented by the government. In September, however, in concert with Gustav von Struve, he crossed the Rhine from Switzerland at the head of a band of volunteers, and proclaimed a republic in Baden. The attempt collapsed; he was captured, and, after suffering eight months' imprisonment, was brought to trial. Fortunately for him, a new rising had just broken out; the mob burst into the court, and he was acquitted. During the short duration of the revolutionary government he was an active member of the most extreme party, but on the arrival of the Prussian troops he succeeded in escaping to France. Thence he went to Geneva, where he came into intercourse with Mazzini; but, unlike most of the German exiles, he was already an adherent of the socialist creed, which Mazzini represented. He had migrated from Switzerland to Giessen, and thence to London, where he lived for thirteen years in close association with Karl Marx. He endured great hardships, but secured a livelihood by teaching and writing; he was a correspondent of the Augsburger Allgemeine Zeitung. The amnesty of 1861 opened for him the way back to Germany, and in 1862 he accepted the post of editor of the Norddeutsche Allgemeine Zeitung, the founder of which was an old revolutionist. Only a few months elapsed before the paper, passed under
with a final appeal (since 1884) to the supreme district court at Innsbruck. Compulsory military service was abolished in 1868, the army having till then been very strong. The principality forms ecclesiastically part of the diocese of Coire, while as regards customs duties it is joined with the Vorarlberg, and as regards postal and coinage arrangements with Austria, which (according to the agreement of 1852, renewed in 1876, by which the principality entered the Austrian customs union) must pay it at least 40,000 crowns annually. In 1904 the revenues of the principality amounted to 888,031 crowns, and its expenditure to 802,165 crowns. There is no public debt.

The county of Vaduz and the lordship of Schellenberg passed through many hands before they were bought in 1613 by the count of Hohenems (to the N. of Feldkirch). In consequence of financial embarrassments, that family had to sell both (the lordship in 1690, the county in 1713) to the Liechtenstein family, which had since the 12th century owned two castles of that name (both now ruined), one in Styria and the other a little S.W. of Vienna. In 1719 these new acquisitions were raised by the emperor into a principality under the name of Liechtenstein which formed subsequently one of the Holy Roman Empire (till 1866) and of the German Confederation (1815-1866), having been sovereign 1806-1815 as well as since 1866.

LIÉGE, one of the nine provinces of Belgium, touching on the east the Dutch province of Limburg and the German district of Khenish Prussia. To a certain extent it may be assumed to represent the old prince-bishopric. Besides the city of Liége it contains the towns of Verviers, Dolhain, Seraing, Huy, etc. The Meuse flows through the centre of the province, and its valley from Huy down to Herstal is one of the most productive mineral districts in Belgium. Much has been done of late years to develop the agricultural resources of the Condroz district south of the Meuse. The area of the province is 723,470 acres, or 1130 sq. m. The population in 1904 was 803,354, showing an average of 763 per sq. m.

LIÉGE (Walloon, Liège, Flemish, Luik, Ger. Liichtich), the capital of the Belgian province that bears its name. It is finely situated on the Meuse, and was long the seat of a prince-bishopric. It is the centre of the Walloon country, and Scott commits a curious mistake in Quentin Durward in making people talk Flemish. The Liége Walloon is the nearest existing approach to the old Romance language. The importance of the city to-day arises from its being the chief manufacturing centre in Belgium, and owing to its large output of arms it has been called the Birmingham of the Netherlands. The productive coal-mines of the Meuse valley, extending from its western suburb of Seraing to the north in the Province of Liege, constitute its chief wealth. At Seraing is established the famous manufacturing firm of Cockrill, whose offices are in the old summer palace of the prince-bishops. The great cathedral of St. Lambert was destroyed and sacked by the French in 1794, and in 1802 the church of St. Paul, dating from the 10th century but rebuilt in the 13th, was declared the cathedral. The law courts are installed in the old palace of the prince-bishops, a building which was constructed by Bishop Everard de la March in 1508 and 1540. The new boulevards are well laid out, especially those flanking the river, and the views of the city and surrounding country are very fine. The university, which has separate schools for mines and arts and manufactures, is one of the largest in the country, and enjoys a high reputation for teaching in its special line.

Liége is a fortified position of far greater strength than is generally appreciated. In the wars of the 18th century Liége played but a small part. It was then defended only by the citadel and a detached fort on the right side of the Meuse, but at a short distance from the river, called the Chartreuse. Marlborough captured these forts in 1703 in preparation for his advance in the following year into Germany which resulted in the victory of Blenheim. The citadel and the Chartreuse were still the only defences of Liége in 1888 when, after long discussions, the Belgian authorities decided on adequately fortifying the two important passes of the Meuse at Liége and Namur. A similar plan was adopted at each place, viz. the construction of a number of detached forts along a perimeter drawn at a distance varying from 4 to 6 m. of the town, so as to shelter it so far as possible from bombardment. At Liége twelve forts were constructed, six on the right bank and six on the left. Those on the right bank beginning at the north and following an eastern curve are Barchon, Évegnée, Fléron, Chaudfontaine, Eboung and Boncelles. The average distance between each fort is 4 m., but Fléron and Chaudfontaine are separated by little over 1 m. in a direct line as they defend the main line of railway from Germany. The six forts on the left bank also commencing at the north, but following a western curve, are Pontisse, Liers, Lantin, Loncin, Hollogne and Flemalle. These forts were constructed under the personal direction of General Blalmont, and are on exactly the same principle as those he designed for the fortifications of Liége, the fortifications being constructed in concrete with casemates, and the heavy guns are raised and lowered automatically. Communication is maintained between the different forts by military roads in all cases, and by steam tramways in some. It is estimated that 25,000 troops would be required for the defence of the twelve forts, but the number is inadequate for the defence of so important and extensive a position. The population of Liége, which in 1875 was only 117,600, had risen by 1900 to 157,760, and in 1905 it was 168,532.

History.—Liége first appears in history about the year 558, at which date St Monulph, bishop of Tongres, built a chapel near the confluence of the Meuse and the Legia. A century later the town, which had grown round this chapel, became the favourite abode of St Lambert, bishop of Tongres, and here he was assassinated. His successor St Hubert raised a splendid church over the tomb of the martyred bishop about 720 and made Liége his residence. It was not, however, until about 930 that the title of bishop of Tongres was abandoned for that of bishop of Liége. The episcopate of Notger (972-1008) was marked by large territorial acquisitions, and the see obtained recognition as an independent principality of the Empire. The popular saying was “Liége owes Notger to God, and everything else to Notger.” By the munificent encouragement of successive bishops Liége became famous during the 11th century as a centre of learning, but the history of the town for centuries records little else than the continuous struggles of the citizens to free themselves from the exactions of their episcopal sovereigns; the aid of the emperor and of the dukes of Brabant being frequently called in to repress the popular risings. In 1316 the citizens compelled Bishop Adolph de la Marck to sign a charter, which made large concessions to the popular demands. It was, however, a triumph of short duration, and the troubles continued, the insurgent subjects now and again obtaining a fleeting success, only to be crushed by the armies of the powerful relatives of the bishops, the houses of Brabant or of Burgundy. During the episcopate of Louis de Bourbon (1456-1484) the Liégeois, having expelled the bishop, had the temerity to declare war on Philip V., duke of Burgundy. Philip’s son, Charles the Bold, utterly defeated them in 1467, and razed the walls of the town to the ground. In the following year the citizens again revolted, and Charles being once more successful delivered up the city to sack and pillage for three days, and deprived the remnant of the citizens of all their privileges. This incident is narrated in Quentin Durward. The long episcopate of Eberhard de la March (1505-1538) was a time of good administration and of quiet, during which the town regained something of its former prosperity. The outbreak of civil war between two factions, named the Cluroux and the Grignoux, marked the opening of the 17th century. Bishop Maximilian Henry of Bavaria (1656-1688) at last put an end to the internal strife and imposed a regulation (règlement) which abolished all the free institutions of the citizens.
and the power of the gilds. Between this date and the outbreak of the French Revolution the chief effects of the prince-bishops were directed to maintaining neutrality in the various wars, and preserving their territory from being ravaged by invading armies. They were only in part successful. Liège was taken by Marlborough in 1702, and the fortress was garrisoned by the Dutch until 1718. The French revolutionary armies overran the principality in 1792, and from 1794 to the fall of Napoleon it was annexed to France, and was known as the department of the Othre. The Congress of Vienna in 1815 decreed that Liège with the other provinces of the southern Netherlands should form part of the new kingdom of the Netherlands under the rule of William I., of the house of Orange. The town of Liège took an active part in the Belgian revolt of 1830, and since that date the ancient principality has been incorporated in the kingdom of Belgium.

The see, which at first bore the name of the bishopric of Tongres, was under the metropolitan jurisdiction of the archbishops of Cologne. The principality comprised besides the town of Liège and its district, the counties of Louvain and Hoorn, the marquesate of Franchimont, and the duchy of Bouillon. According to Bu 存在无法确定的字符和符号

LIEGE, an adjective implying the mutual relationship of a feudal superior and his vassal; the word is used as a substantive of the feudal superior, more usually in this sense, however, in the form "liege lord," and also of the vassals, his "lieges." Hence the word is often used of the loyal subjects of a sovereign, with no reference to feudal ties. It appears that ligetals or ligetis, the medieval Latin term for a chattel of the superior, was restricted to a particular form of homage. According to N. Broussel (Nouvel examen de l'usage général des feux en France, 1772) the homage of a "liege" was a stronger form of the ordinary homage, the especial distinction being that while the ordinary vassal only undertook forty days' military service, the liege promised to serve as long as the war might last, in which his superior was engaged (cf. Ducange, Glossarium, s.v. "ligius").

The etymology of the word has been much discussed. It comes into English through the O. Fr. lige or liege, Med. Lat. ligius. This was early connected with the Lat. ligatus, bound, ligare, to bind, from the sense of the obligation of the vassal to his lord, but this has been generally abandoned. Broussel takes the Med. Lat. liga, i.e., foedus, conferatio, the English "league," as the origin. Ducange connects it with the word lites, which appears in a gloss of the Salic law, and is defined as a scripthibus, servus globae. The more usually accepted derivation is now from the Old High Ger. ledig, or ledig, meaning "free." (Mod. Ger. ledig means unemployed, vacuous.) This meaning was extended by the 12th and 13th centuries to a man of the common condition (Ger. Diener, 1235, of a word "ledig-man" (quoted in Ducange, Glossarium, s.v.). Proinde affecto sumus ligius homae quod Teutonicus dicit ledighman. Skeat, in explaining the application of "free" to such a relationship as that subsisting between a feudal superior and his vassal, says "a liege lord" seems to have been the lord of a free band; and his lieges, though serving under him, were privileged men, free from all other obligations; their name being due to their freedom, not to their service" (Etym. Dict., ed. 1880). A. Luchaire (Manuel des institutions françaises, 1892, p. 189, n. 1) considers it difficult to call a man "free" who is under a strict obligation to another; further that the "liege" was not free from all obligation to a third party, for the charters prove without doubt that the "liege men" owed duty to more than one lord.

LIEGNITZ, a town in Germany, in the Prussian province of Silesia, picturesquely situated on the Kitzbachi, just above its junction with the Schwarzwasser, and 40 m. W.N.W. of Breslau, on the main line of railway to Berlin via Sommerfeld. Pop. (1885) 43,547. (1905) 50,710. It consists of an old town, surrounded by pleasant, shady promenades, and several well-built suburbs. The most prominent building is the palace, formerly the residence of the dukes of Liegnitz, rebuilt after a fire in 1835 and now used as the administrative offices of the district. The Ritter Akademie, founded by the emperor Joseph I. in 1708 for the education of the young Silesian nobles, was reconstructed as a gymnasium in 1810. The Roman Catholic church of St John, with two fine towers, contains the burial vault of the dukes. The principal Lutheran church, that of SS. Peter and Paul (restored in 1892-1894), dates from the 14th century. The manufactures are considerable, the chief articles made being cloth, wool, leather, tobacco, pianos and machinery. It trade in grain and its cattle-markets are likewise important. The large market gardens in the suburbs grow vegetables of considerable annual value.

Liegnitz is first mentioned in an historical document in the year 1094. In 1163 it became the seat of the dukes of Liegnitz, who greatly improved and enlarged it. The dukes were members of the Order of the Teutonic Knights, which gave many kings to Poland. During the Thirty Years' War Liegnitz was taken by the Swedes, but was soon recaptured by the Imperialists. The Saxon army also defeated the imperial troops near Liegnitz in 1634. On the death of the last duke of Liegnitz in 1675, the duchy came into the possession of the Empire, which retained it until the Prussian conquest of Silesia in 1742. On the 15th of August 1760 Frederick the Great gained a decisive victory near Liegnitz over the Austrians, and in August 1813 Blücher defeated the French in the neighbourhood at the battle of the Kutzbach. During the 19th century Liegnitz rapidly increased in population and prosperity. In 1906 the German autumn manoeuvres were held over the terrain formerly the scene of the great battles already mentioned.

LIEV, in law. The word lien is literally the French for a bond, cord or chain, and keeping in mind that meaning we see in what respect it differs from a pledge on the one hand and a mortgage on the other. It is the bond which attaches a creditor's right to a debtor's property, but which gives no right ad rem, i.e., to property in the thing; if the property is in the possession of the creditor he may retain it, but in the absence of statute he cannot sell to recover what is due to him without the ordinary legal process against the debtor; and if it is not in possession, the law would indeed assist him to seize the property, and will hold it for him, and enable him to sell it in due course and pay himself out of the proceeds, but does not give him the property itself. It is difficult to say at what period the term lien made its appearance in English law; it probably came from more than one source. In fact, it was used for any right for any mortgage for any property, not specially defined by other better recognized species of title.

The possessory lien of a tradesman for work done on the thing, of a carrier for his hire, and of an innkeeper for his bill, would seem to be an inherent right which must have been in existence from the dawn, or before the dawn, of civilization. Probably the man who made or repaired weapons in the Stone Age was careful not to deliver them until he received what was stipulated for, but it is also probable that the term itself resulted from the infusion of the civil law of Rome into the common law of England which the Norman Conquest brought about, and that it represents the "tact pledge" of the civil law. As might be expected, so far as the possessory lien is concerned the common law and civil law, and probably the laws of all countries, whether civilized or not, coincide; but there are many differences with respect to other species of lien. For instance, by the common
Lien

Law—in this respect a legacy of the feudal system—a landlord has a lien over his tenant's furniture and effects for rent due, which can be enforced without the assistance of the law simply by the landlord taking possession, personally or by his agent, and selling enough to satisfy his claim; whereas the maritime lien is more distinctly the product of the civil law, and is only found and used in admiralty proceedings, the high court of admiralty having been founded upon the civil law, and still (except so far as restrained by the common-law courts prior to the amalgamation and co-ordination of the various courts by the Judicature Acts, and as affected by statute law) acting upon it. The peculiar effects of this maritime lien are discussed below. There is also a class of liens, usually called equitable liens (e.g. that of an unpaid vendor of real property over the property sold), which are akin to the nature of the civil law rather than of the common law. The word lien does not frequently occur in statute law, but it is found in the extension of the common-law 'carriers' or shipowners,' in the Merchant Shipping Act 1854; in the definition, extension and limitation of the vendor's lien; in the Factors Act 1877, and the Sale of Goods Act 1893; in granting a maritime lien to a shipmaster for his wages and disbursements, and in regulating that of the seamen in the Merchant Shipping Act 1894; and in the equity jurisdiction of the county courts 1888.

Common-Law Liens.—These may be either particular, i.e. a right over one or more specified articles for a particular debt, or general, i.e. for all debts owing to the creditor by the debtor. The requisites for a particular lien are, firstly, that the creditor should be in possession of the article; secondly, that the debt should be incurred with reference to the article; and thirdly, that the amount of the debt should be certain. It may be created by express contract, by implied contract (such as the usage of a particular trade or business), or as a consequence of the legal relation existing between the parties. As an example of the first, a shipowner has a lien for the cargo for his freight; but though the shipper agrees to pay dead freight in addition, i.e. to pay freight on any space in the ship which he fails to occupy with his cargo, the shipowner has no lien on the cargo for such dead freight except by express agreement. The most usual form of the second is that which is termed a possessory lien—the right a ship-repairer has to retain a ship in his yard till he is paid for the repairs executed upon her, and the right a cobbler has to retain a pair of shoes till he is paid for the repairs done to them. But this lien is only in respect of the work done on, and consequent benefit received by, the subject of the lien. Hence an agistor of cattle has no lien at common law upon them for the value of the pasturage consumed, though he may have one by agreement; nor a conveyancer upon deeds which he has not drawn, but which are in his possession for reference. The most common example of the third is that of a carrier, who is bound by law to carry for all persons, and has, therefore, a lien for the price of the carriage of the goods carried. It has been held that even if the goods are stolen, and entrusted to the carrier by the thief, the carrier can hold them for the price of the carriage against the rightful owner. Of the same nature is the common-law lien of an innkeeper on the baggage of his customer for the amount of his account, he being under a legal obligation to entertain travellers generally. Another instance of the same class is where a person has obtained possession of certain things over which he claims to hold a lien in the exercise of a legal right. For example, when a lord of a manor has seized cattle as estrays, he has a lien upon them for the expenses of their keep as against the real owner; but the holder's claim must be specific, otherwise a general tender of compensation releases the lien.

A general lien is a right of a creditor to retain property, not merely for charges relating to it specifically, but for debts due on a general account. This not being a common-law right, is viewed in the English courts with the greatest jealousy, and to be enforced must be strictly proved. This can be done by proof either of an express or implied contract or of a general usage of trade. The first of these is established by the ordinary methods or by previous dealings between the parties on such terms; the second is recognized in certain businesses; it would probably be exceedingly difficult, if not impossible, to extend it at the present time to any other trades. When, however, a lien by general usage has once been judicially established, it becomes part of the Law Merchant, and the courts are bound to recognize and enforce it. The best known and most important instance is the right of a solicitor to retain papers in his hands belonging to his client until his account is settled. The solicitor's lien, though probably more commonly enforced than any other, is of no great antiquity in English law, the earliest reported case of it being in the reign of James II.; but it is now of a twofold nature. In the first place there is the retaining lien. This is similar in kind to other possessory liens, but of a general nature attaching to all papers of the client, and even to his money, up to the amount of the solicitor's bill, in the hands of the solicitor in the ordinary course of business. There are certain exceptions which seem to have crept in for the same reason as the solicitor's lien itself, i.e. general convenience of litigation; such exceptions are the will of the client after his decease, and proceedings in bankruptcy. In the latter case the actual possessory lien is given up, the solicitor's interests and priorities being protected by the courts, and it may be said that the giving up the papers is really only a means of enforcing the lien they give in the bankruptcy proceedings. In the second place there is what is called a charging lien—more correctly classed under the head of equitable lien, since it does not require possession, but is a lien the solicitor holds over property recovered or preserved for his client. He had the lien on an order by the court upon a fund in court by the common law, but as to property generally it was only given by 23 & 24 Vict. c. 127, § 28; and it has been held to attach to property recovered in a probate action (ex parte Tweed, C.A. 1890, 2 Q.B. 167). A banker's lien is also high in a bank for a person's amount due to him to be held for his customer for money due on a general balance. Other general liens, judicially established, are those of wharffingers, brokers and factor (which are in their nature akin to those of solicitors and bankers), and of calico printers, packers of goods, fullers (at all events at Exeter), dyers and millers; but in all these special trades it is probable that the true reason is that the account due was for one continuous transaction. The calico would come to be printed, the goods to be packed, the cloth to be bleached, the silk to be dyed, and the corn to be ground, in separate parcels, and at different times, but all as one undertaking; and they are therefore, though spoken of as instances of general lien, only adaptations by the courts of the doctrine of particular lien to special peculiarities of business. In none of these cases would the lien exist, in the absence of special agreement, for other matters of account, such as money lent or goods sold.

Equitable Liens.—"Where equity has jurisdiction to enforce rights and obligations growing out of an executory contract," e.g. in a suit for specific performance, "this equitable theory of remedies cannot be carried out unless the notion is admitted that the contract creates some right or interest in or over specific property, which the decree of the court can lay hold of, and by means of which the equitable relief can be made efficient. The doctrine of equitable liens supplies this necessary element; and it was introduced for the sole purpose of furnishing a ground for these specific remedies which equity confers, operating upon particular identified property instead of the general pecuniary recoveries granted by courts of common law. It follows, therefore, that in a large class of executory contracts express and implied, which the common law regards as creating no property, right nor interest analogous to property, but only a mere personal right to obligation, equity recognizes in addition to the personal obligation a particular right over the thing with which the contract deals, which it calls a lien, and which though not property is analogous to property, and by means of which the plaintiff is enabled to follow the identical thing and to enforce the defendant's obligation by a remedy which operates directly on the thing.

1 This right, however, is not absolute, but depends on the custom of the port (Raitt v. Mitchell, 1815, 4 Camp. 140).
The theory of equitable liens has its ultimate foundation, therefore, in contracts express or implied which either deal or in some manner relate to specific property, such as a tract of land, particular chattels or securities, a certain fund and the like. It is necessary to divest oneself of the purely legal notion concerning the effects of such contracts, and to recognize the fact that equity regards them as creating a charge upon, or hypothecation of, the specific thing, by means of which the personal obligation arising from the agreement may be more effectively enforced than by a mere pecuniary recovery at law" (Pomeroy, 2 Eq. Jur. 232).

This description from an American text-book seems to give at once the fullest and most concise definition and description of an equitable lien. It differs essentially from a common-law lien, inasmuch as in the latter possession or occupation is as a rule necessary, whereas in the equitable lien the person claiming the lien is seldom in possession or occupation of the property, its object being to obtain the possession wholly or partially.

A special instance of such a lien is that claimed by a publisher over the copyright of a book which he has agreed to publish on terms which are not complied with—for example, the author attempting to get the book published elsewhere. It cannot perhaps be said that this has been absolutely decided to exist, but a strong opinion of the English court of exchequer towards the close of the 18th century was expressed in its favour (Brook v. Wentworth, 3 Anstruther 881). Other instances are the charging lien of a solicitor, and the lien of a person on improvements effected by him on the property of another who "lies by" and allows the work to be done before claiming the property. So also of a trustee for expenses lawfully incurred about the trust property. The power of a limited liability company to create a lien upon its own shares was in 1901 established (Allen v. Gold Refs. Co., C.A. 1900, 1 Ch. 656).

Maritime Liens. —Maritime lien differs from all the others yet considered, in its more elastic nature. Where a maritime lien has once attached to property—and it may and generally does attach without possession—it will continue to attach, unless lost by laches, so long as the thing to which it attaches exists, notwithstanding changes in the possession of and property in the thing, and notwithstanding that the new possessor or owner may be entirely ignorant of its existence; and even if enforced it leaves the owner's personal liability for any balance unrealized intact (the "Gemina," 1890, P. 285). So far as England is concerned, it must be borne in mind that the courts of admiralty were conducted in accordance with the principles of civil law, and in that law both the pledge with possession and the hypothecation without possession were well recognized. The extreme convenience of such a right as the latter with regard to such essentially movable chattels as ships is apparent. Strictly speaking, a maritime lien is confined to cases arising in those matters over which the courts of admiralty had original jurisdiction, viz., collisions at sea, seamen's wages, salvage and bottomry, in all of which cases the appropriate remedy is a proceeding in rem in the admiralty court. In the first of these—collisions at sea—if there were no maritime lien there would frequently be no remedy at all. When two ships have collided at sea it may well be that the innocent ship knows neither the name nor the nationality of the wrongdoer, and the vessel may escape with slight damage and not have to make a port of refuge in the neighbourhood. Months afterwards it is ascertained that she was a foreign ship, and in the interval she has changed owners. Then, were it not a fact that a maritime lien invisible to the wrongdoer nevertheless attaches itself to his ship at the moment of collision, and continues to attach, the unfortunate owner of the innocent ship would have no remedy, except the doubtful one of pursuing the former owner of the wrong-doing vessel in his own country in a personal action where such proceedings are allowed—which is by no means the case in all foreign countries. The same reasons apply, though not possibly with quite the same force, to the other classes of cases mentioned.

Between 1840 and 1873 the jurisdiction of the admiralty court was largely extended. At the latter date it was merged in the probate, divorce and admiralty division of the High Court of Justice. Since the merger questions have arisen as to how far the enlargement of jurisdiction has extended the principle of maritime lien. An interesting article on this subject by J. Mansfield, barrister-at-law, will be found in the Law Quarterly Review, vol. iv., October 1888. It must be sufficient to state here that where legislation has extended the already existing jurisdiction to which a maritime lien pertained, the maritime lien is extended to the subject matter, but that where a new jurisdiction is given, or where a jurisdiction formerly existing without a maritime lien is extended, no maritime lien is given, though even then the extended jurisdiction can be enforced by proceedings in rem. Of the first class of extended jurisdictions are collisions, salvage and seamen's wages. Prior to 1840 the court of admiralty only had jurisdiction over these when occurring or earned on the high seas. The jurisdiction, and with it the time limit, is exclusive, 1840, N.C. 447, 76. In a case of a ship in collision in rem or salvage, and as to seamen's wages, whereas they were dependent on the earning of freight, they are now free from any such limitation; and also, whereas the remedy in rem was limited to seamen's wages not earned under a special contract, it is now extended to all seamen's wages, and also to a master's wages and disbursements, and the maritime lien covers all these. The new jurisdiction given over claims for damage to cargo carried into any port in England or Wales, and on appeal from the county courts over all claims for damage to cargo under £300, though it may be prosecuted by proceedings in rem, i.e., by arrest of the ship, yet confers no maritime lien; and so also in the case of claims by material men (builders and fitters-out of ships) and for necessaries. Even though in the latter case the admiralty court had jurisdiction previously to 1840, whereas the necessaries were supplied on the high seas, yet as it could not be shown that such jurisdiction had ever been held to confer a maritime lien, no such lien is given. Even now there is much doubt as to whether towage confers a maritime lien or not, the services rendered being pursuant to contract, and frequently to a contract made verbally or in writing on the high seas, and being rendered also to a great extent on the high seas. In these cases and to that extent the high court of admiralty would have had original jurisdiction. But prior to 1840 towage, as now rendered by steam tugs expressly employed for the service, was practically unknown, and therefore there was no established catena of precedent to show the exercise of a maritime lien. It may be argued on the one hand that towage is only a modified form of salvage, and therefore entitled to a maritime lien, and on the other that it is only a form of necessary power supplied like a new sail or mast to a ship to enable her to complete her voyage expeditiously, and therefore of the nature of necessaries, and as such not entitled to a maritime lien.

The matter is not of academical interest only, for though in the case of an inward-bound ship the tug owner can make use of his statutory right of proceeding in rem, and so obtain much of the benefit of a maritime lien, yet in the case of an outward-bound ship, if she once gets away without payment, and the agent or other authorized person refuses or is unable to pay, the tug owner's claim may, on the return of the ship to a British port, be met by an allegation of a change of ownership, which defeats his right of proceeding at all if he has no maritime lien; whereas if he has a maritime lien he can still proceed against the ship and recover his claim, if he has not been guilty of laches.

A convenient division of the special liens other than possessory on ships may be made by classifying them as maritime, statutory-maritime or quasi-maritime, and statutory. The first attach only in case of damage done by collision of ships on the high seas, salvage on the high seas, bottomry and seamen's wages so far as freight has been earned; the second attach in cases of damage by collision within the body of a county, salvage within the body of a county, towage and bottomry where there has been earned, master's wages and disbursements. These two classes continue to attach notwithstanding a change of ownership without notice of the lien, if there have been no laches in enforcing it (the "Faulkner," 1852, N.C. 467; the "Kong Marien," 1851, P. 223). The third class, which only give a right to proceed
in rem, i.e. against the ship itself, attach, so long as there is no bona fide change of ownership, without citing the owners, in all cases of claims for damage to ship and of claims for damage to cargo where no owner is domiciled in England or Wales. Irrespective of this, however, if only in some cases, by breach of contract, on the face of the bill of lading, but also of breaches of contract to carry where the damage does not exceed £300, when the suit must be commenced in a county court having admiralty jurisdiction; and in cases of claims for negligence, there is no ship’s broker’s legal liability to the extent of wages earned even under a special contract by masters and mariners, and of claims for towage. In all three classes the lien also exists over cargo where the suit from its nature extends to it, as in salvage and in some cases of bottomry or respondencia, and in cases where the proceedings are taken against cargo by the shipowner for a breach of contract (cargo ex "Argos" and the "Hewsons," 1873, L.R. 5 P.C. 134; the "Aina," 1860, 5 Ex. D. 227).

In addition, and in those countries such as the United States which have adopted her jurisprudence in maritime matters generally, the doctrine of maritime lien, or that which is substituted for it, is very differently treated. Speaking generally, those states which have adopted the Napoleonic code or modifications of them—France, Italy, Spain, Holland, Portugal, Belgium, Greece, Turkey, and to some extent Russia—have adopted a maritime lien the civil-law principle of privileged debts. Amongst these in all cases are found claims for salvage, wages, bottomry, under certain restrictions, and necessary. Each of these has a privileged claim against the ship, and in some cases against freight and cargo as well, but it is a matter of very great importance that, even if all claims for collision damage (which as we have seen confers a maritime lien, and one of a very high order, in Great Britain) confers no privilege against the wrong-doing ship, whilst in all these countries an owner can get rid of his personal liability by recording a lien, and if the ship is sunk, escape all liability whilst retaining any insurance there may be. This, indeed, was at one time the law of Great Britain; the measure of damage was limited by the value of the ship, and for the first time in the 9th century he get rid of his liability for damage by abandoning the ship and freight. A different rule prevails in Germany and the Scandinavian states. There claims relating to the ship, unless the owner has specially relinquished the rights of lien, claim priority over a mortgage. The claim is limited ab initio to ship and freight, except in the case of seamen’s wages, which do confer a personal claim so far as they have been earned on a voyage or passage completed prior to the loss of the vessel. In all maritime states, however, except Spain, a provisional arrest of the ship is allowed, and thus between the privilege accorded to the debt and the power to arrest till bail is given or the ship abandoned to creditors, a condition of things analogous to the maritime lien is established; especially as these claims when the proper legal steps have been taken to render them valid—usually by endorsement on the ship’s papers on board, or by registration at her port of registry—attach to the ship and follow her into the hands of a purchaser. They are in fact notice to him of the incurring.

Duration of Lien.—So long as the party claiming the lien at common law retains the property, the lien continues, notwithstanding the debt in respect of which it is claimed becoming barred by the Statute of Limitations (Higgins v. Scott, 1831, 2 B. & Ald. 413). But if he takes proceedings at law to recover the debt, and on a sale of the goods to satisfy the judgment, purchases them himself, he so alters the nature of the possession that he loses his lien (Jacobs v. Latour, 5 Bing. 130). An equitable lien probably in all cases continues, provided the purchaser of the subject matter has notice of the lien at the time of his purchase. A maritime lien is in no respect subject to the Statute of Limitations, and continues in force notwithstanding a change in the ownership of the property without notice, and is only terminated when it has once attached, by laches on the part of the person claiming it (the "Kong Magnati," 1891, P. 275).

Therefore, in the case of the owner’s lien in the hands of the salvors by 4 Anne c. 16 (Stat. Rev. & 5 Anne c. 3) all suits for seamen’s wages in the Admiralty must be brought within six years.

Ranking of Maritime Liens.—There may be several claimants holding maritime and other liens on the same vessel. For example, a foreign vessel comes into collision by her own fault and is damaged and her cargo also; she is assisted into port by salvors and ultimately under a towage agreement, and put into the hands of a shipwright who does necessary repairs. The innocent party to the collision has a maritime lien for his damage, and the seamen for their wages; the cargo owner has a suit in rem or a statutory lien for damage, and the shipwright a possessory lien for the value of his repairs, while the tugs certainly have a right in rem and possibly a maritime lien also in the nature of salvage. The value of the property may be insufficient to pay all claims, and it becomes a matter of great consequence to settle whether any, and if so which, have priority over the others, or whether all rank alike and have to divide the proceeds of the property pro rata amongst them. The following general rules apply: liens for benefits conferred rank against the fund in the inverse, and those for the repairation of damage sustained in the direct order of their attaching to the res; as between the two classes those last mentioned rank before those first mentioned of earlier date; as between liens of the same class and the same date, the first claimant has priority over others who have not taken action. The courts of admiralty, however, allow equitable considerations, and enter into the question of marshalling assets. For example, one claimant has a lien on two funds, or an effective right of action in addition to his lien, and another claimant has only a lien upon one fund, the first claimant will be obliged to exhaust his second remedy before coming into competition with the second. As regards possessory liens, the shipwright takes the ship as she stands, i.e. with her incumbrances, and it appears that the lien for seaman’s wages takes precedence of a solicitor’s lien for costs, under a charging order made in pursuance of the Solicitors Act 1860, § 28.

Subject to equitable considerations, the true principle appears to be that services rendered under an actual or implied contract, or by virtue of a statutory right, entitle the person rendering them to attach the proceeds of the vessel without any lien, whether the latter is a proprietor of the vessel, and therefore liable for damage done by her—hence the priority of the damage lien—but, directly it has attached, benefits conferred on the property by enabling it to reach port in safety benefit the holder of the damage lien in common with all other prior holders of maritime liens. It is less easy to see why two damage liens the earlier should take precedence of the later, except on the principle that the res which came into collision the first time was already liable to damage, and the lien for the second collision arises not on the same res, but on the same ship before a recovery of her for the first lien upon her for the first collision, and where there was more than one damage lien, and also liens for benefits conferred prior to the first collision between the two collisions and subsequent to the second collision must have priority in order to meet the peculiar circumstances. The claim of a mortgagee is normally deferred to all maritime liens, whether they are for benefits conferred on the property in which he is interested or for damage done by it, and also for the same reason to the possessory lien of the shipwright, but both the possessory lien of the shipwright and the claim of the mortgagee take precedence over a claim for necessaries, which only confers a statutory lien or a right to proceed in rem in certain cases. In the case of a right to enter a vessel to re-take possession, where the privileged debts are all set out in order of priority in these codes, though, as has been already pointed out, the lien for damage by collision—the most important in English law—has no counterpart in the former.

Stoppage in Transit.—This is a lien held by an unpaid vendor in certain cases over goods sold after they have passed out of his actual possession. It has been much discussed whether it is an equitable or common-law right or lien. The fact appears to be that it has always been a part of the Law Merchant, which, properly speaking, is itself a part of the common law of England unless inconsistent with it. This particular right was, in the first instance, held by a court of equity to be equitable and not contrary to English law, and by that decision this particular part of the Law Merchant was approved and became part of the common law of England (see per Lord Abinger in Gibson v. Carruthers, 8 M. & W., p. 336 et seq.). It may be described as a lien by the Law Merchant, decided by equity to be part of the common law, but in its nature partaking rather of the character of an equitable lien than one at common law. It is “a right which arises solely upon the insolvency of the buyer, and is based on the plain reason of justice and equity that one man’s goods shall not be applied to the payment of another man’s debts. If, therefore, after the vendor has delivered the goods out of his own possession and put them in the hands of a carrier for delivery to the buyer, he discovers that the buyer is insolvent, he may re-take the goods if he can before they reach the buyer’s possession, and thus avoid having his property applied to paying debts due by the buyer to other people” (Benjamin on Sales, 2nd ed., 286). This right, though only recognized by English law in 1690, is highly favoured by
the courts on account of its intrinsic justice, and extends to quasi-vendors, or persons in the same position, such as consignors who have bought on behalf of a principal and forwarded the goods. It is, however, defeated by a lawful transfer of the document of title to the goods by the vendor to a third person, who takes it bona fide and for valuable consideration (Factors Act 1889; Sale of Goods Act 1893).

Assignment or Transfer of Lien.—A lien being a personal right acquired in respect of personal services, it cannot, as a rule, be assigned or transferred; but here again there are exceptions. The personal representative of the holder of a possessory lien on his decease would probably in all cases be held entitled to it; and it has been held that the lien over a client’s papers remains with the firm of solicitors notwithstanding changes in the constitution of the firm (Gregory v. Cresswell, 14 L.J. Ch. 300). So also where a solicitor, having a lien on documents for his costs, assigned the debt to his bankers with the benefit of the lien, it was held that the bankers might enforce such lien in equity. But though a tradesman has a lien on the property of his customer for his charges for work done upon it, where the property is delivered to him by a servant and continues to be in his possession, such a lien cannot be transferred to the servant, even if he has paid the money himself; and the lien does not exist at all if the servant was acting without authority in delivering the goods, except where (as in the case of a common carrier) he is bound to receive the goods, in which case he retains his lien for the carriage against the rightful owner. Where, however, there is a lien on property of any sort not in possession, a person acquiring the property with knowledge of the lien takes it subject to such lien. This applies to equitable liens, and cannot apply to those common-law liens in which possession is necessary.

It is, however, true that by statute certain common-law liens can be transferred, e.g. under the Merchant Shipping Act a master of a ship having a lien upon cargo for his freight can transfer the possession of the cargo to a wharfinger, and with it the lien (Merchant Shipping Act 1894, § 404). In this case, however, though the matter is simplified by the statute, if the wharfinger was constituted the agent or servant of the shipmaster, his possession would be the possession of the shipmaster, in which case there would be no real transfer of the lien; therefore the common-law doctrine is not altered, only greater facilities for the furtherance of trade are given by the statute, enabling the wharfinger to act in his own name without reference to his principal, who may be at the other side of the world. So also a lien may be retained, notwithstanding that the property passes out of possession, where it has to be deposited in some special place (such as the Custom-House) to comply with the law. Seamen cannot sell or assign or in any way part with their maritime lien for wages (Merchant Shipping Act 1894, § 166), but, nevertheless, with the sanction of the court, a person who pays seamen their wages is entitled to stand in their place and exercise their rights (the Cornelia Henrietta, 1866, L.R. 1 Ad. & Ec. 51).

Waiver.—Any parting with the possession of goods is in general a waiver of the lien upon them; for example, when a factor having a lien on the goods of his principal gives them to a carrier to be carried at the expense of his principal, even if undisclosed, he waives his lien, and has no right to stop the goods in transitu to recover it; so also where a coach-builder who has a lien on a carriage for repairs allows the owner from time to time to take it out for use without expressly reserving his lien, he has waived it, nor has he a lien for the standage of the carriage except by express agreement, as mere standage does not give a possessory lien. It has even been held that where a portion of goods sold as a whole for a lump sum has been taken away and paid for proportionately, the conversion has taken place and the lien for the residue of the unpaid purchase-money has gone (Gurr v. Cuthbert, 1843, 12 L.J. Ex. 309). Again, an acceptance of security for a debt is inconsistent with the existence of a lien, as it substitutes the credit of the owner for the material guarantee of the thing itself, and so acts as a waiver of the lien. For the same reason even an agreement to take security is a waiver of the lien, though the security is not, in fact, given (Alliance Bank v. Brown, 11 L.T. 332).

Sale of Goods under Lien.—At common law the lien only gives a right to retain the goods, and ultimately to sell by legal process, against the owner; but in certain cases a right has been given by statute to sell without the intervention of legal process, such as the right of an innkeeper to sell the goods of his customer for his unpaid account (Innkeepers Act 1878, § 1), the right of a wharfinger to sell goods entrusted to him by a shipowner with a lien upon them for freight, and also for their own charges (Merchant Shipping Act 1894, §§ 407, 408), and of a railway company to sell goods for their charges (Railway Clauses Act 1845, § 97). Property affected by an equitable lien or a maritime lien cannot be sold by the holder of the lien without the intervention of the court to enforce an order, or judgment of the court. In Admiralty cases, where a sale is necessary, no bail having been given and the property being under arrest, the sale is usually made by the marshal in London, but may be elsewhere on the parties concerned showing that a better price is likely to be obtained.

Within the United States, speaking very generally, the law relating to liens is that of England, but there are some considerable differences occasioned by three principal causes. (1) Some of the Southern States, notably Louisiana, have never adopted the common law of England. When that state became one of the United States of North America it had (and still preserves) its own system of law. In this respect the law is practically identical with the Code Napoleonic, which, again speaking generally, substitutes privileges for liens, i.e., gives certain claims a prior right to others against particular property. These privileges being strictly in praesenti interpretatione cannot be extended by any principle analogous to the English doctrine of equitable liens. (2) Probably in consequence of the United States and the several states composing it having had a more democratic government than Great Britain, in their earlier years at all events, certain liens have been created by statute in several states in the interest of the working classes which have no parallel in Great Britain, e.g., in some states workmen employed in building a house or a ship have a lien upon the building or ship for their unpaid wages. This statutory lien partakes rather of the nature of an equitable than of a common-law lien, as the property is not in the possession of the workman, and it may be doubted whether the right thus conferred is more beneficial to the workman than the priority his wages have in bankruptcy proceedings in England. Some of the states have also practically extended the maritime lien to matters over which it was never contended for in England. (3) By the constitution of the United States the admiralty and inter-state jurisdiction is vested in the federal as distinguished from the state courts, and these federal courts have not been liable to have their jurisdiction curtailed by prohibition from courts of common law, as the court of admiralty had in England up to the time of the Judicature Acts; consequently the maritime lien in the United States extends further than it does in England, even after recent enlargements; it covers claims for necessaries and by material men (see Maritime Lien), as well as collision, salvage, wages, bottomry and damage to cargo.

Difficulties connected with lien occasionally arise in the federal courts in admiralty cases, from the conflict on the subject between the municipal law of the state where the court happens to sit and the admiralty law; but as there is no power to prohibit the federal court, its view of the admiralty law based on the civil law prevails. More serious difficulties arise where a federal court has to try inter-state questions, where the two states have different laws on the subject of lien; one for example, like Louisiana, following the civil law, and the other the common law and equitable practice of Great Britain. The question as to which law is to govern in such a case can hardly be said to be decided. “The question whether equitable liens can exist to be enforced in Louisiana by the federal courts, notwithstanding its restrictive law of privileges, is still an open one” (Doris,
Contracts of Pledge, 517; and see Burdon Sugar Refining Co. v. Payne, 167 U.S. 127.

British Colonies.—In those colonies which before the formation of the Canadian federation were known as Upper Canada and the Maritime Provinces of British North America, and in the several Australasian states where the English common law is enforced except as modified by colonial statute, the principles of lien, whether by common law or equitable or maritime, discussed above with reference to England, will prevail; but questions not dissimilar to those treated of in reference to the United States may arise where colonies have come to the crown of Great Britain by cession, and where different systems of municipal law are enforced. For example, in Lower Canada the law of France prior to the Revolution occupies the place of the common law in England, but is generally regulated by a code very similar to the Code Napoleon; in Mauritius and its dependencies the Code Napoleon itself is in force except so far as modified by subsequent ordinances. In South Africa, and to some extent in Ceylon and Guiana, Roman-Dutch law is in force; in the island of Trinidad old Spanish law, prior to the introduction of the present civil code of Spain, is the basis of jurisprudence. Each several system of law requires to be studied on the point; but, speaking generally, apart from the possession and maintenance of jurisdiction, functions, and rights in admiralty courts, it may be assumed that the rules of the civil law, giving a privilege or priority in certain specified cases rather than a lien as understood in English law, prevail in those colonies where the English law is not in force.

(L. W. R.)

LIERRE (Flemish, Lier), a town in the province of Antwerp, Belgium; 9 m. S.E. of Antwerp. Pop. (1904) 24,229. It carries on a brisk industry in silk fabrics. Its church of St Gommare was finished in 1557 and contains three fine glass windows, the gift of the archduke Maximilian, to celebrate his wedding with Mary of Burgundy.

Liestal, the capital (since 1833) of the half canton of Basel-Stadt in Switzerland. It is a well-built but uninteresting industrial town, situated on the left bank of the Ergolz stream, and is the most populous town in the entire canton of Basel, after Basel itself. By rail it is 8½ m. S.E. of Basel, and 15 m. N.W. of Olten. In the 15th-century town hall (Rathaus) is preserved the golden drinking cup of Charles the Bold, duke of Burgundy, which was taken at the battle of Nancy in 1477. In 1900 the population was 5403, all German-speaking Swiss Protestants. The town was sold by its lord to the bishop of Basel, who, in 1400, sold it to the city of Basel, at whose hands it suffered much in the Peasants' War of 1525, and so consented gladly to the separation of 1833.

Lieutenant, one who takes the place, office and duty of and acts on behalf of a superior or other person. The word in English preserves the form of the French original (from lieu, place, tenant, holding), which is the equivalent of the Latin locum tenens, one holding the place of another. The usual English pronunciation appears early, the word being frequently spelled lieutentant, lieutenant or lieutenant in the 14th and 15th centuries. The modern American pronunciation is lieutenant, while the German is represented by the present form of the word Leutnant. In French history, lieutenant du roi (locum tenens regis) was a title borne by the officer sent with military powers to represent the king in certain provinces. With wider powers and functions, both civil as well as military, and holding authority throughout an entire province, such a representative of the king was called lieutenant général du roi. The first appointment of these officials dates from the reign of Philip IV. In the 18th century the administration of the provinces was in the hands of gouverneurs, to whom the lieutenants du roi became subordinates. The titles lieutenant civil or criminel and lieutenant général de police have been borne by certain judicial officers in France (see Châtelot and Bailiff: Bailiff). As the title of the representative of the sovereign, "lieutenant" in English usage appears in the title of the lord lieutenant of Ireland, and of the lords lieutenant of the counties of the United Kingdom (see below).

LIERRE—LIEUTENANT

The most general use of the word is as the name of a grade of military and military officer. It is common in this application to nearly every nation that most of the provinces: be given In Italy and Spain the first part of the word is omitted, and an Italian and Spanish officer bearing this rank are called tenente or teniente respectively. In the British and most other navies the lieutenants are the commissioned officers next in rank to commanders, or second class of captains. Originally the lieutenant was a soldier who aided, and in case of need replaced, the captain, who, until the latter half of the 17th century, was not necessarily a seaman in any navy. At first one lieutenant was carried, and only in the largest ships. The number was gradually increased, and the lieutenants formed a numerous corps. At the close of the Napoleonic War in 1815 there were 3211 lieutenants in the British navy. Lieutenants now often qualify for special duties such as navigation, or gunnery, or the management of torpedoes. In the British army a lieutenant is a subaltern officer ranking next below a captain and above a second lieutenant. In the United States of America subalterns are classified as first lieutenants and second lieutenants. In France the two grades are lieutenant and sous-lieutenant, while in Germany the Leutnant is the lower of the two ranks, the higher being Ober-leutnant. In the British army, the rank of "lieutenant," in the French army, that of "captain," in the Spanish army, that of "teniente," and in the Austrian army, that of "lieutenant," was formerly the second class in the actual line of officers and commanded the colonel's company or troop, and ranked as junior captain, or "punny captain," as he was called by Cromwell's soldiers.

The lieutenants of a county in England and Wales and in Ireland, is the term applied to officers from the reign of Henry VIII. (or, according to some, Edward VI.), when the military functions of the sheriff were handed over to him. He was responsible for the efficiency of the militia of the county, and afterwards of the yeomanry and volunteers. He was the commander of all the forces in the county, and the officers he appointed. By the Rescript of the court of the Forces Act 1871, the jurisdiction, duties and command exercised by the lord lieutenants was revested in the crown, but the power of recommending for first appointments was reserved to the lord lieutenants. By the Territorial and Reserve Forces Act 1907, the lord lieutenant of a county was constituted president of the county association. The office of lord lieutenant is honorary, and is held during the royal pleasure, but virtually for life. Appointment to the office is by letters patent under the great seal. Usually, though not necessarily, the person appointed lord lieutenant is also appointed custos rotulorum (q.v.). Appointments to the county bench of magistrates are usually made on the recommendation of the lord lieutenant (see Magistrate).

A deputy lieutenant (denoted frequently by the addition of the letters D.L. after a person's name) is a deputy of a lord lieutenant of a county. His appointment and qualifications previous to 1808 were regulated by the Military Act 1802. By s. 30 of that act the lieutenant of each county was required from time to time to appoint such properly qualified persons as he thought fit, living within the county, to be deputy lieutenants. At least twenty had to be appointed for each county. If there were so many qualified; if less than twenty were qualified, then all the duly qualified persons in the county were to be appointed. The appointments were subject to the sovereign's approval, and a return of all appointments to, and removals from, the office had to be laid before parliament annually. To qualify for the position in 1907, the deputy lieutenant had to be (a) a peer of the realm, or the heir-apparent of such a peer, having a place of residence within the county; or (b) have in possession an estate in land in the United Kingdom of the yearly value of £200. In the case of (b) the place was that of a such a person; or (d) have a clearly yearly income from personal property within the United Kingdom of not less than £200 (s. 33). If the lieutenant were absent from the United Kingdom, or through illness or other cause were unable to act, the sovereign might authorize any three of the deputy lieutenants to act in his or her place, or to appoint a deputy lieutenant to act as vice-lieutenant. Otherwise, the duties of the office were practically nominal, except that a deputy lieutenant might attest militia recruits and administer the oath of allegiance of the militia. (See Administration of the Forces.) The court of aldermen of the British crown, and the formation of county associations to administer the territorial army, placed increased duties on deputy lieutenants, and it was publicly announced that the king's approval of appointments to that position would be given in the case of gentlemen who had served for ten years in some force of the crown, or had rendered eminent service in connexion with a county association.

The lord lieutenant of Ireland is the head of the executive in that country. He represents his sovereign and maintains the formalities of government, the business of government being entrusted to the
LIFE, the popular name for the activity peculiar to protoplasm (q.v.). This conception has been extended by analogy to phenomena different in kind, such as the activities of masses of water or of air, or of machinery, or by another analogy, to the duration of a composite structure, and by imagination to real or supposed phenomena such as the manifestations of incorporeal entities. From the point of view of exact science life is associated with matter, is displayed only by living bodies, by all living bodies, and is what distinguishes living bodies from bodies that are not alive. Herbert Spencer's formula that life is "the continuous adjustment of internal relations to external relations" was the result of a profound and subtle analysis, but omits the fundamental consideration that we know life only as a quality of and in association with living matter.

In developing our conception we must discard from consideration the complexities that arise from the organization of the higher living bodies, the differences between one living animal and another, or between plant and animal. Such differentiations and integrations of living bodies are the subject-matter of discussions on evolution; some will see in the play of circumambient media, natural or supernatural, on the simplest forms of living matter, sufficient explanation of the development of such matter into the highest forms of living organisms; others will regard the potency of such living matter so to develop as a mystery, and peculiar quality that must be added to the conception of life. Choice amongst these alternatives need not complicate investigation of the nature of life. The explanation that serves for the evolution of living matter, the vehicle of life, will serve for the evolution of life. What we have to deal with here is life in its simplest form.

The definition of life must really be a description of the essential characters of life, and we must set out with an investigation of the characters of living substance with the special object of detecting the differences between organisms and unorganized matter, and the differences between dead and living organized matter.

Living substance (see PROTOPLASM), as it now exists in all animals and plants, is particular, consisting of elementary organisms living independently, or grouped in communities, the communities forming the bodies of the higher animals and plants. These small particles or larger communities are subject to accidents, internal or external, which destroy them, immediately or slowly, and thus life ceases; or they may wear out, or become clogged by the products of their own activity. There is no reason to regard the mortality of protoplasm and the consequent limited duration of life as more than the necessary consequence of particular character of living matter (see LONGEVITY).

Protoplasm, the living material, contains only a few elements, all of which are extremely common and none of which is peculiar to it. These elements, however, form compounds characteristic of living substance and for the most part peculiar to it. Proteid, which consists of carbon, hydrogen, nitrogen, oxygen and sulphur, is present in all protoplasm, is the most complex of all organic bodies, and, so far, is known only from organic bodies. A multitude of minor and simpler organic compounds, of which carbohydrates and fats are the best known, occur in different protoplasm in varying forms and proportions, and are much less isolated from the inorganic world. They may be stages in the elaboration or disintegration of protoplasm, and although they were at one time believed to occur only as products of living matter, are gradually being conquered by the synthetic chemist. Finally, protoplasm contains various inorganic substances, such as salts and water, the latter giving it its varying degrees of liquid consistency.

We attain, therefore, our first generalized description of life as the property or peculiar quality of a substance composed of none but the more common elements, but of these elements grouped in various ways to form compounds ranging from proteid, the most complex of known substances to the simplest salts. The living substance, moreover, has its mixture of elaborate and simple compounds associated in a fashion that is peculiar. The older writers have spoken of protoplasm or the cell as being in a sense "manufactured articles"; in the more modern view such a conception is replaced by the statement that protoplasm and the cell have behind them a long historical architecture. Both ideas, or both modes of expressing what is fundamentally the same idea, have this in common, that life is not a sum of the qualities of the chemical elements contained in protoplasm, but a function first of the peculiar architecture of the mixture, and then of the high complexity of the compounds contained in the mixture. The qualities of water are no sum of the qualities of oxygen and hydrogen, and still less can we expect to explain the qualities of life without regard to the immense complexity of the living substance.

We must now examine in more detail the differences which exist or have been alleged to exist between living organisms and inorganic bodies. There is no essential difference in structure. Confusion has arisen in regard to this point from attempts to compare organized bodies with crystals, the comparison having been suggested by the view that as crystals present the highest type of inorganic structure, it was reasonable to compare them with organic matter. Differences between crystals and organized bodies have no bearing on the problem of life, for organic substance must be compared with a liquid rather than with a crystal, and differs in structure no more from inorganic liquids than these do amongst themselves, and less than they differ from crystals. Living matter is a mixture of substances chiefly dissolved in water; the comparison with the crystals has led to a supposed distinction in the mode of growth, crystals growing by the superficial apposition of new particles and living substance by intussusception. But inorganic liquids also grow in the latter mode, as when a soluble substance is added to them.

The phenomena of movement do not supply any absolute distinction. Although these are the most obvious characters of life, they cannot be detected in quiescent seeds, which we know to be alive, and they are displayed in a fashion very like life by inorganic foams brought in contact with liquids of different composition. Irritability, again, although a notable quality of living substance, is not peculiar to it, for many inorganic substances respond to external stimulation by definite changes. Instability, again, which lies at the root of Spencer's definition "continuous adjustment of internal relations to external relations" is displayed by living matter in very varying degrees from the apparent absolute quiescence of frozen seeds to the activity of the central nervous system, whilst there is a similar range amongst inorganic substances.

The phenomena of reproduction present no fundamental distinction. Most living bodies, it is true, are capable of reproduction, but there are many without this capacity, whilst, on the other hand, it would be difficult to draw an effective distinction between that reproduction of simple organisms which consists of a sub-division of their substance with consequent resumption of symmetry by the separate pieces, and the breaking up of a drop of mercury into a number of droplets. Consideration of the mode of origin reveals a more real if not an absolute distinction. All living substance so far as is known at present (see BIOGENESIS) arises only from already existing living substance. It is to be noticed, however, that green plants have the power of building up living substance from inorganic material, and there is a certain analogy between the
building up of new living material only in association with pre-existing living material, and the greater readiness with which certain inorganic reactions take place if there already be present some trace of the result of the reaction.

The real distinction between living matter and inorganic matter is chemical. Living substance always contains proteid, and although we know that proteid contains only certain inorganic elements, we know neither how these are combined to form proteid, nor any way in which proteid can be brought into existence except in the presence of previously existing proteid. The central position of the problem of life lies in the chemistry of proteid, and until that has been fully explored, we are unable to say that there is any problem of life behind the problem of proteid.

Comparison of living and lifeless organic matter presents the initial difficulty that we cannot draw an exact line between a living and a dead organism. The higher “warm-blooded” creatures appear to present the simplest case and in their life-history there seems to be a point at which we can say “that which was alive is now dead.” We judge from some major arrest of activity, as when the heart ceases to beat. Long after this, however, various tissues remain alive and active, and the event to which we give the name of death is no more than a superficially visible stage in a series of changes. In less highly intertised cases, such as “cold-blooded” vertebrates, the point of death is less conspicuous, and when we carry our observations further down the scale of animal life, there cease to be any salient phase in the slow transition from life to death.

The distinction between life and death is made more difficult by a consideration of cases of so-called “arrested vitality.” If credit can be given to the stories of Indian fakirs, it appears that human beings can pass voluntarily into a state of suspended animation that may last for weeks. The state of involuntary trance, sometimes mistaken for death, is a similar occurrence. A. Leeuwenhoek, in 1719, made the remarkable discovery, since abundantly confirmed, that many animalcule, notably tardigrades and rotifers, may be completely desiccated and remain in that condition for long periods without losing the power of awaking to active life when moistened with water. W. Preyer has more recently investigated the matter and has given it the name “anabiosis.” Later observers have found similar occurrences in the cases of small nematodes, rotifers and bacteria. The capacity of plant seeds to remain dry and inactive for very long periods is still better known. It has been supposed that in these cases the situation was “cold-blooded.” To say that the condition of anabiosis was merely one in which the metabolism was too faint to be perceptible by ordinary methods of observation, but that the elaborate experiments of W. Kochs would seem to show that a complete arrest of vital activity is compatible with viabiliy. The categories, “alive” and “dead,” are not sufficiently distinct for us to add to our conception of life by comparing them. A living organism usually displays active metabolism of proteid, but the metabolism may slow down, actually cease and yet reawaken; a dead organism is one in which the metabolism has ceased and does not reawaken.

Origin of Life.—It is plain that we cannot discuss adequately the origin of life or the possibility of the artificial construction of living matter (see ABIOGENESIS and BIOGENESIS) until the chemistry of protoplasm and specially of proteid is more advanced. The investigations of O. Bütchli have shown how a model of protoplasm can be manufactured. Very finely triturated soluble particles are rubbed into a smooth paste with an oil of the requisite consistency. A fragment of such a paste brought into a liquid in which the solid particles are soluble, slowly expands into a homecomb like foam equal in weight of the minute vesicles being films of oil, and the contents being the soluble particles dissolved in droplets of the circumbent liquid. Such a model, properly constructed, that is to say, with the vesicles of the foam microscopic in size, is a marvellous imitation of the appearance of protoplasm, being distinguishable from it only by a greater symmetry. The nicely balanced conditions of solution produce a state of unstable equilibrium, with the result that internal streaming movements and changes of shape and chemical changes of position in the model simulate closely the corresponding manifestations in real protoplasm. The model has no power of recuperation; in a comparatively short time equilibrium is restored and the resemblance with protoplasm disappears. But it suggests a method by which, when the chemistry of protoplasm and proteid is better known, the proper substances which compose protoplasm may be brought together to form a simple kind of protoplasm.

It has been suggested from time to time that conditions very unlike those now existing were necessary for the first appearance of life, and must be repeated if living matter is to be constructed artificially. No support for such a view can be derived from observations of the existing conditions of life. The chemical elements involved are abundant; the physical conditions of temperature pressure and so forth at which living matter is most active, and within the limits of which it is confined, are familiar and almost constant in the world around us. On the other hand, it may be that the initial conditions for the synthesis of proteid are different from those under which proteid and living matter display their activities. E. Pfliiger has argued that the analogies between living proteid and the compounds of cyanogen are so striking that he suggests cyanogen as the starting-point of protoplasm. Cyanogen and its compounds, so far as we know, arise only in a state of incandescent heat. Pfliiger suggests that such compounds arose when the surface of the earth was incandescent, and that in the long process of cooling, compounds of cyanogen and hydrocarbons passed into living protoplasm by such processes of transformation and polymerization as are familiar in the chemical groups in question, and by the acquisition of water and oxygen. His theory is in consonance with the interpretation of the structure of protoplasm as having behind it a long historical architecture and leads to the obvious conclusion that if protoplasm be constructed artificially it will be by a series of stages and that the product will be simpler than any of the existing animals or plants.

Until greater knowledge of protoplasm and particularly of proteid has been acquired, there is no scientific room for the suggestion that there is a mysterious factor differentiating living matter from other matter and life from other activities. We have to scale the walls, open the windows, and explore the castle before cying out that it is so marvellous that it must contain ghastly secrets. But supposing, theories of the origin of life apart from doctrines of special creation or of a primitive and slow spontaneous generation are mere fantastic speculations. The most striking of these suggests an extra-terrestrial origin. H. E. Richter appears to have been the first to propound the idea that life came to this planet as cosmic dust or in meteorites thrown off from stars and planets. Towards the end of the 19th century Lord Kelvin (then Sir W. THOMSON) and H. von HELMHOLTZ independently raised and discussed the possibility of such an origin of terrestrial life, laying stress on the presence of hydrocarbons in meteoric stones and on the indications of their presence revealed by the spectra of the tails of comets. W. Preyer has criticized such views, grouping them under the phrase “theory of cosmozoa,” and has suggested that living matter preceded inorganic matter. Preyer’s view, however, enlarges the conception of life until it can be applied to the phenomena of incandescent gases and has no relation to ideas of life derived from observation of the living matter we know.

(P. C. M.)
LIFE-BOAT, and LIFE-SAVING SERVICE. The article on drowning and life-saving (q.v.) deals generally with the means of saving life at sea, but under this heading it is convenient to include the appliances connected specially with the life-boat service. The ordinary open boat is unsuited for life-saving in a stormy sea, and numerous contrivances, in regard to which the lead came from England, have been made for securing the best type of life-boat.

The first life-boat was conceived and designed by Lionel Lukin, a London coachbuilder, in 1785. Encouraged by the prince of Wales (George IV.), Lukin fitted up a Norway yawl as a life-boat, took out a patent for it, and wrote a pamphlet descriptive of his "Insubmersible Boat." Buoyancy he obtained by means of a projecting gunwale of cork and air-chambers inside—one of these being at the bow, another at the stern. Stability he secured by a false iron keel. The self-righting and self-emptying principles he seems not to have thought of; at all events he did not compass them. Despite the patronage of the prince, Lukin went to his grave a neglected and disappointed man. But he was not altogether unsuccessful, for, at the request of the Rev. Dr Shairp, Lukin fitted up a cobbler as an "unimmersible" life-boat, which was launched at Bamborough, saved several lives the first year and afterwards saved many lives and much property.

Public apathy in regard to shipwreck was temporarily swept away by the wreck of the "Adventure" of Newcastle in 1789. This vessel was stranded only 300 yds. from the shore, and her crew dropped, one by one, into the raging breakers in presence of thousands of spectators, none of whom dared to put off in an ordinary boat to the rescue. An excited meeting among the people of South Shields followed; a committee was formed, and premiums were offered for the best models of a life-boat. This called forth many plans, of which those of William Would-have, a painter, and Henry Greathead, a boatbuilder, of South Shields, were selected. The committee awarded the prize to the latter, and, adopting the good points of both models, gave the order for the construction of their boat to Greathead. This boat was rendered buoyant by nearly 7 cwts. of cork, and had very raking stem and stern-posts, with great curvature of keel. It did good service, and Greathead was well rewarded; nevertheless no other life-boat was launched till 1798, when the duke of Northumberland ordered Greathead to build him a life-boat which he endowed. This boat also did good service, and its owner ordered another in 1800 for Oporto. In the same year Mr Cathcart Dempster ordered one for St Andrews, where, two years later, it saved twelve lives. Thus the value of life-boats began to be recognized, and before the end of 1803 Greathead had built thirty-one boats—eighteen for England, five for Scotland and eight for foreign lands. Nevertheless, public interest in life-boats was not thoroughly aroused till 1823.

In that year Sir William Hillary, Bart., stood forth to champion the life-boat cause. Sir William dwelt in the Isle of Man, and had assisted with his own hand in the saving of three hundred and five lives. In conjunction with two members of parliament—Mr. Thomas Wilson and Mr George Hibbert—Hillary founded the "Royal National Institution for the Preservation of Life from Shipwreck." This, perhaps the grandest of England's charitable societies, and now named the "Royal National Life-boat Institution," was founded on the 4th of March 1824. The king patronized it; the archbishop of Canterbury presided at its birth; the most eloquent men in the land—among them Wilberforce—pleaded the cause; nevertheless, the institution began its career with a sum of only £626. In the first year twelve new life-boats were built and placed at different stations, besides which thirty-nine life-boats had been stationed on the British shores by benevolent individuals and by independent associations over which the institution exercised no control though it often assisted them. In its early years the institution placed the mortar apparatus of Captain Manby at many stations, and provided for the wants of sailors and others saved from shipwreck,—a duty subsequently discharged by the "Shipwrecked Fishermen and Mariners' Royal Benevolent Society." At the date of the institution's second report it had contributed to the saving of three hundred and forty-two lives, either by its own life-saving apparatus or by other means for which it had granted rewards. With fluctuating success, both as regards means and results, the institution continued its good work—saving many lives, and occasionally losing a few brave men in its tremendous battles with the sea. Since the adoption of the self-righting boats, loss of life in the service has been comparatively small and infrequent.

Towards the middle of the 19th century the life-boat cause appeared to lose interest with the British public, though the life-saving work was prosecuted with unremitting zeal, but the increasing loss of life by shipwreck, and a few unusually severe disasters to life-boats, brought about the reorganization of the society in 1830. The Prince Consort became vice-patron of the institution in conjunction with the king of the Belguins, and Queen Victoria, who had been its patron since her accession, became an annual contributor to its funds. In 1831 the duke of Northumberland became president, and from that time forward a tide of prosperity set in, unprecedented in the history of benevolent institutions; both in regard to the number of successful rescues and to the pecuniary aid received. In 1830 its committee undertook the immediate superintendence of all the life-boat work on the coasts, with the aid of local committees. Periodical inspections, quarterly exercise of crews, fixed rates of payments to coxswains and men, and quarterly reports were instituted, at the time when the self-righting self-emptying boat came into being. This boat was the result of a hundred guinea prize, offered by the president, for the best model of a life-boat, with another hundred to defray the cost of a boat built on the model chosen. In reply to the offer no fewer than two hundred and eighty models were sent in, not only from all parts of the United Kingdom, but from France, Germany, Holland and the United States of America. The prize was gained by Mr James Bouching of Great Yarmouth, whose model, slightly modified by Mr James Peake, one of the committee of inspection, was still further improved as time and experience suggested (see below).

The necessity of maintaining a thoroughly efficient life-boat service is now generally recognized by the people not only of Great Britain, but also of those other countries on the European Continent and America which have a sea-board, and of the British colonies, and numerous life-boat services have been founded more or less on the lines of the Royal National Life-boat Institution. The British Institution was again reorganized in 1883; it has since greatly developed both in its life-saving efficiency and financially, and has been spoken of in the highest terms as regards its management by successive governments—a Select Committee of the House of Commons in 1879 reporting to the House that the thanks of the whole community were due to the Institution for its energy and good management. On the death of Queen Victoria in January 1901 she was succeeded as patron of the Institution by Edward VII., who as prince of Wales had been its president for several years. At the close of 1900 the Royal National Life-boat Institution had received an endowment of £60,000, and the total number of lives for the saving of which the committee of management had granted rewards since the establishment of the Institution in 1824 was 47,983. At this time there were only seventeen life-boats on the coast of the United Kingdom which did not belong to the Institution. In 1882 the total amount of money received by the Institution from all sources was £57,797, whereas in 1901 the total amount received had increased to £70,293. In 1908 the receipts were £115,303, the expenditure £60,335.
and others. Under its provisions numerous highly dangerous wrecks have been removed.

In 1893 the chairman of the Institution moved a resolution in the House of Commons that, in order to decrease the serious loss of life from shipwreck on the coast, the British Government should provide either telephonic or telegraphic communication between all the coast-guard stations and signal stations on the coast of the United Kingdom; and that where there are no coast-guard stations the post offices nearest to the life-boat stations should be electrically connected, the object being to give the earliest possible information to the life-boat authorities at all times, by day and night, when the life-boats are required for service; and further, that a Royal Commission should be appointed to consider the advisability of electrically connecting the rock lighthouses, light-ships, &c., with the shore. The resolution was agreed to without a division, and its intention has been practically carried out, the results obtained having proved most valuable in the saving of life.

On the 1st of January 1898 a pension and gratuity scheme was introduced by the committee of management, under which life-boat coxswains, bowmen and signalmen of long and meritorious service, retiring at the age of fifty, or after twenty-five years, are entitled to receive special allowances as a reward for their good services. These payments act as an incentive to the men to discharge their duties satisfactorily, they at the same time assist the committee of management in their effort to obtain the best men for the work.

For many years the Institution has given compensation to any who may have received injury while employed in the service, besides granting liberal help to the widows and dependents of any in the service who lose their lives when endeavouring to rescue others.

A very marked advance in improvement in design and suitability for service has been made in the life-boat since the reorganization of the Institution in 1883, but principally since 1887, when, as the result of an accident in December 1886 to two self-righting life-boats in Lancashire, twenty-seven out of twenty-nine of the men who manned them were drowned. At this time a permanent technical sub-committee was appointed by the Institution, whose object was, with the assistance of an eminent consulting naval architect—a new post created—and the Institution's official experts, to give its careful attention to the designing of improvements in the life-boat and its equipment, and to the scientific consideration of any inventions or proposals submitted by the public, with a view to adopting them if of practical utility. Whereas in 1881 the self-righting life-boat of that time was looked upon as the Institution's special life-boat, and there were very few life-boats in the Institution's fleet not of that type, at the close of 1901 the life-boats of the Institution included 60 non-self-righting boats of various types, known by the following designations: Steam life-boats 4, Cromer 3, Lamb and White 1, Liverpool 14, Norfolk and Suffolk 19, tubular 1, Watson 18. In 1901 a steam-tug was placed at Padstow for use solely in conjunction with the life-boats on the north coast of Cornwall. The self-righting life-boat of 1901 was a very different boat from that of 1881. The Institution's present policy is to allow the men who man the life-boats, after having seen and tried by reputation the various types, to select in that which they have the most confidence.

The present life-boat of the self-righting type (fig. 2) differs materially from its predecessor, the stability being increased and the riding power greatly improved. The test of efficiency in this last quality was formerly considered sufficient if the boat would quickly right herself in smooth water without her crew and gear, but every self-righting life-boat now built by the Institution will right with her full crew and gear on board, with her sails set and the anchor down. Most of the larger self-righting boats are furnished with "centre-boards" or "drop-keels" of varying size and weight, which can be used at pleasure, and materially add to their weather qualities. The drop-keel was for the first time placed in a life-boat in 1885.

Steam was first introduced into a life-boat in 1890, when the Institution, after very full inquiry and consideration,
LIFE-BOAT, AND LIFE-SAVING SERVICE

previously held by all competent judges that a mechanically-propelled life-boat, suitable for service in heavy weather, was a problem surrounded by so many and great difficulties that even the most sanguine experts dared not hope for an early solution of it. This type of boat (fig. 3) has proved very useful. It is, however, fully recognized that boats of this description can necessarily be used at only a very limited number of stations, and where there is a harbour which never dries out. The highest speed attained by the first hydraulic steam life-boat was rather more than 9 knots, and that secured in the latest 9½ knots. In 1909 the fleet of the Institution included 4 steam life-boats and 8 motor life-boats. The experiments with motor life-boats in previous years had proved successful.

The other types of pulling and sailing life-boats are all non-self-righting, and are specially suitable for the requirements of the different parts of the coast on which they are placed. Their various qualities will be understood by a glance at the illustrations (figs. 4, 5, 6, 7 and 8).

The Institution continues to build life-boats of different sizes according to the requirements of the various points of the coast at which they are placed, but of late years the tendency has been generally to increase the dimensions of the boats. This change of policy is mainly due to the fact that the small

coasters and fishing-boats have in great measure disappeared, their places being taken by steamers and steam trawlers. The cost of the building and equipping of pulling and sailing life-boats has materially increased, more especially since 1898, the increase being mainly due to improvements and the seriously augmented charges for materials and labour. In 1881 the average cost of a fully-equipped life-boat and carriage was £650, whereas at the end of 1901 it amounted to £1000, and the average annual cost of maintaining a station having risen to about £125.

The transporting-carriage continues to be a most important part of the equipment of life-boats, generally of the self-righting type, and is indispensable where it is necessary to launch the boats at any point not in the immediate vicinity of the boathouse. It is not, however, usual to supply carriages to boats of larger dimensions than 37 ft. in length by 9 ft. beam, those in excess as regards length and beam being either launched by means of special slipways or kept afloat. The transporting-carriage of to-day has been rendered particularly useful at places where the beach is soft, sandy or shingly, by the introduction in 1888 of Tipping's sand-plates. They are composed of an endless plate-way or jointed wheel tyre fitted to the main wheels of the carriage, thereby enabling the boat to be transferred with rapidity and with greatly decreased labour over beach and soft sand. Further efficiency in launching has also been attained at many stations by the introduction of the use of pulling-poles, attached to the transporting-carriages, and

of horse launching-poles, first used in 1892. Fig. 9 gives a view of the modern transporting-carriage fitted with Tipping's sand- or wheel-plates.

The life-belt has since 1898 been considerably improved, being now less cumbersome than formerly, and more comfortable. The feature of the principal improvement is the reduction in length of the corks under the arms of the wearer and the rounding-off of the upper portions, the result being that considerably more freedom is provided for the arms. The maximum extra buoyancy has thereby been reduced from 25 lb. to 22 lb., which is more than sufficient to support a man heavily clothed with his head and shoulders above the water, or to enable him to

support another person besides himself. Numerous life-belts of very varied descriptions, and made of all sorts of materials, have been patented, but it is generally agreed that for life-boat work the cork life-belt of the Institution has not yet been equalled.
have been produced in all shapes and sizes, but apparently nothing indispensable has as yet been brought out. Those interested in life-saving appliances were hopeful that the Paris

A, deck; E, wale, or fender; H, drop-keel.

Exhibition of 1890 would have produced some life-saving invention which might prove a benefit to the civilized world, but so lacking in real merit were the life-saving exhibits that the jury of experts were unable to award to any of the 435 competitors the Andrew Pollok prize of £4000 for the best method or device for saving life from shipwreck.

The **rocket apparatus**, which in the United Kingdom is under the management of the coast-guard, renders excellent service in life-saving. This, next to the life-boat, is the most important and successful means by which shipwrecked persons are rescued on the British shores. Many vessels are cast every year on the rocky parts of the coasts, under cliffs, where no life-boat could be of service. In such places the rocket alone is available.

The **rocket apparatus** consists of five principal parts, viz. the rocket, the rocket-line, the whip, the hawser, and the life-buoy. The mode of working it is as follows. A rocket, having a light line attached to it, is fired over the wreck. By means of this line the wrecked crew haul out the whip, which is a double or endless line, rove through a block with a tail attached to it. The tail-block, having been detached from the rocket-line, is fastened to a mast, or other portion of the wreck, high above the water. By means of the whip the rescuers haul off the hawser, to which is hung the traveling or sling life-buoy. When one end of the hawser has been made fast to the mast, about 18 in. above the whip, and its other end
to tackle fixed to an anchor on shore, the life-buoy is run out by the rescuers, and the shipwrecked persons, getting into it at one time, are hauled ashore. Sometimes, in cases of urgency, the life-buoy is worked by means of the whip alone, without the hawser. Captain G. W. Manby, F.R.S., in 1807 invented, or at least introduced, the mortar apparatus, on which the system of the rocket apparatus, which superseded it in England, is founded. Previously, however, in 1791, the idea of throwing a rope from a wreck to the shore by means of a shell from a mortar had occurred to Sergeant Bell of the Royal Artillery, and about the same time, to a Frenchman named La Père, both of whom made successful experiments with their apparatus. In the same year (1807) a rocket was proposed by Mr. Trengrouse of Helston in Cornwall, also a hand and lead line as means of communicating with vessels in distress. The *hearsling* was a fruit of the latter suggestion. In 1814 forty-five mortar stations were established, and Manby received £2000, in addition to previous grants, in acknowledgment of the good service rendered by his invention. Mr. John Dennett of Newport, Isle of Wight, introduced the rocket, which was afterwards extensively used. In 1826 four places in the Isle of Wight were supplied with Dennett's rockets, but it was not till after government had taken the apparatus

under its own control, in 1855, that the rocket invented by Colonel Boxer was adopted. Its peculiar characteristic lies in the combination of two rockets in one case, one being a continuation of the other, so that, after the first compartment has carried the machine to its full elevation, the second gives it an additional impetus whereby a great increase of range is obtained. (R. M. B.; C. D.)

**United States.**—In the extent of coast line covered, magnitude of operations and the extraordinary success which has crowned its efforts, the life-saving service of the United States is not surpassed by any other institution of its kind in the world. Notwithstanding the exposed and dangerous nature of the coasts flanking and stretching between the approaches to the principal seaports, and the immense amount of shipping concentrating upon them, the loss of life among a total of 121,459 persons imperilled by marine casualty within the scope of the operations of the service from its organization in 1871 to the 30th of June 1907, was less than 1%, and even this small proportion is made up largely of persons washed overboard immediately upon the striking of vessels and before any assistance could reach them, or lost in attempts to land in their own boats, and people thrown into the sea by the capsizing of small craft. In the scheme of the service, next in importance to the saving of life is the saving of property from marine disaster, for which no salvage or reward is allowed. During the period named vessels and cargoes to the value of nearly two hundred million dollars were saved, while only about a quarter as much was lost.
LIFE-BOAT, AND LIFE-SAVING SERVICE

The first government life-saving stations were plain boat-houses erected on the coast of New Jersey in 1848, each equipped with a fisherman's surf-boat and a mortar and life-car with accessories. Prior to this time, as early as 1789, a benevolent organization known as the Massachusetts Humane Society had erected rude huts along the coast of that state, followed by a station at Cohasset in 1807 equipped with a boat for use by volunteer crews. Others were subsequently added. Between 1840 and 1870 this society secured appropriations from Congress aggregating $140,000. It still maintains sixty-nine stations on the Massachusetts coast. The government service was extended in 1849 to the coast of Long Island, and in 1850 one station was placed on the Rhode Island coast. In 1854 the appointment of keepers for the New Jersey and Long Island stations, and a superintendent for each of these stations, was authorized by law. Volunteer crews were dependent upon until 1870, when Congress authorized crews at each alternate station for the three winter months.

The present system was inaugurated in 1871 by Sumner L. Kimball, who in that year was appointed chief of the Revenue Cutter Service, which had charge of the few existing stations. He recommended an appropriation of $200,000 and authority for the employment of crews for all stations for such periods as were deemed necessary, which were granted. The existing stations were thoroughly overhauled and put in condition for the housing of crews; necessary boats and equipment were furnished; incapable keepers, who had been appointed largely for political reasons, were supplanted by experienced men; additional stations were established; all were manned by capable surfmen; the merit system for appointments and promotions was inaugurated; a beach patrol system was introduced, together with a system of signals; and regulations for the government of the service were promulgated. The result of the transformation was immediate and striking. At the expiration of a year it was found not a life had been lost within the domain of the service; and at the end of the second year the record was almost identical, but one life having been lost, although the service had been extended to embrace the dangerous coast of Cape Cod. Legislation was subsequently secured, totally eliminating politics in the choice of officers and men, and making other provisions necessary for the completion of the system. The service continued to grow in extent and importance until, in 1878, it was separated from the Revenue Cutter Service and organized into a separate bureau of the Treasury, its administration being placed in the hands of a general superintendent appointed by the president and confirmed by the senate, his term of office being limited only by the will of the president. Mr Kimball was appointed to the position, which he still held in 1909.

The service embraces thirty districts, with 280 stations located at selected points upon the sea and lake coasts. Nine districts on the Atlantic and Gulf coasts contain 201 stations, including nine houses of refuge on the Florida coast, each in charge of a keeper only, without crews; three districts on the Great Lakes contain 14 stations, including one at the falls of the Ohio river, Louisville, Kentucky; and one district on the Pacific coast contains 18 stations, including one at Nome, Alaska.

The general administration of the service is conducted by a general superintendent and an inspector of life-saving stations and two superintendents of construction of life-saving stations detailed from the Revenue Cutter Service; a district superintendent for each district; and a chief engineer of the Revenue Cutter Service "to perform such duties in connection with the conduct of the service as the general superintendent may require." There is also an advisory board on life-saving appliances consisting of experts, to consider devices and inventions submitted for superintendence.

Station crews are composed of a keeper and six to eight surfmen, with an additional man during the winter months at most of the stations on the Atlantic coast. The surfmen are entirely selected from the most approved and experienced men by a thorough physical examination. The keepers are subject to annual physical examinations after attaining the age of fifty-five. Stations on the Atlantic and Gulf coasts are manned from August 1st to April 1st. On the lakes the active season covers the period of navigation, from about April 1st to early in December. The falls station at Louisville, and all stations on the Pacific coast, are in commission continuously. One station, located in Dorchester Bay, an expanse of water within Boston harbour, where numerous yachts rendezvous and many accidents occur, which, with the one at Louisville are believed to be the only floating life-saving stations in the world, is manned from May 1st to November 15th. Its equipment includes a steam tug and two gasoline launches, the latter with hand carry-buys. The life-saving apparatus is parceled out and extending from the stern to nearly amidships. The Louisville stations guard the falls of the Ohio river, where life is much endangered from accidents to vessels passing over the falls and small craft. The life-saving apparatus in use at these stations is the life-saving apparatus, by which very many men are being rescued from the verge of certain loss; and have become a matter of public record. The service now employs 28 boats, 4 launches, and 2 steam launches. The boats are built separately. Each station has a look-out tower for the day watch.

The principal apparatus consists of surf- and life-boats, Lyke gun and breeches-buoy apparatus and life-car. The Lyke gun and Cunningham line-carrying mortar are available at selected stations on account of their greater range, but their use is rarely necessary. The crews are drilled daily in some portion of rescue work, as practice in maneuvering, upsetting and righting boats, with the breeches-buoy, in the resuscitation of the apparently drowned and in signalling. The district officers upon their quarterly visits examine the crews orally and by drill, recording the proficiency of each, and on their return to the home ports deliver their reports and furnish a copy of the report to the general superintendent. For watch and patrol the day of twenty-four hours is divided into periods of four or five hours each. Day watches are stood by one man in the look-out tower or at the station. In the middle of each period the lookout apprises the watch of the water conditions, etc., and watches for the arrival of the next watch at the keypost which marks the end of his beat. On discovering a vessel standing into danger the patrolman burns a Coston signal, which emits a brilliant red flare, to warn the vessel of her danger. The patrolman also has a large red flag in view, which is lowered in case of an alarm. The alarm is given by ringing a bell; the bell is rung by pulling a hand bell attached to a wall in the inner part of the block. The station is then divided into three divisions, and the watch is maintained in thick or stormy weather in the daytime. Between adjacent stations a record of the patrol is made by the exchange of brass checks; elsewhere the patrolman carries a watch and keeps a record of his beat. The watch and patrol duty is given to the person who is physically able to perform it, and no person is placed on this duty except the person who is in active service. The station frequently wanders in the hands of the men during the inclement months, or by the members of the crew. The gear is unloaded, and while being set up—the members of the crew performing their several allotted parts simultaneously—the keeper fires a small charge at the wreck with the Lyle gun, a small bronze cannon weighing, with its 18th elongated iron projectile to which the line is attached, slightly more than 200 lb, and having an extreme range of about 700 yds., in which is wounded the whale for more than 400 yds. This gun was the invention of a patent, afterwards Colonel) David A. Lyle, U.S. Navy. Shortlines are of three sizes, 1/4, 3/8, and 1/2 of an inch diameter, designated respectively Nos. 4, 7 and 9. The two outer lines are of the same size, the inner one is larger, having been fastened within reach of the persons on the wreck, an endless rope rove through a tail-block is sent out by it with instructions printed in English and French on a tally-board, by which the tail-line is led to the wreckers. The inner line is led to the shore and the whale is suspended and drawn between the ship and the shore with the whole line. The life-car can also be used as a boat between ship and shore and brought up into the boat to save the use of a harmer. The breeches-buoy is a large canvas cylinder, with a small part of the rope attached to it, which wades behind and above the wheels, the life-line being fastened either from within or without, and a few perfections to admit air with raised edges to exclude water. At wreck operations during the night the shore is illuminated by powerful acetylene (calium carbide) lights. If any of the rescued persons are frostbite...
LIFE-BOAT, AND LIFE-SAVING SERVICE

as often happens, or are injured or sick, first aid and simple remedies are furnished them. Dry clothing, supplied by the Women's National Relief Association, is also furnished to survivors, which the destitute are allowed to keep.

however, have now been transformed into power boats without the sacrifice of any of their essential qualities. The installation of power is effected by introducing a 25 H.P. four-cycle gasoline motor, weighing with its fittings, tanks, &c., about 800 lb. The engine is installed in the after air chamber, with the starting crank, reversing clutches, &c., recessed into the bulkhead to protect them from accidents. These boats attain a speed of from 7 to 9 m. an hour, and have proved extremely efficient. A new power life-boat (fig. 10) on somewhat improved lines, 36 ft. in length, and equipped with

Self-righting and self-bailing life-boats, patterned after those used in England and other countries, have heretofore been used at most of the Lake stations and at points on the ocean coast where they can be readily launched from ways. Most of these boats, a 35-40 H.P. gasoline engine, promises to prove still more efficient. A number of surf-boats have also been equipped with gasoline engines of from 5 to 7 H.P., for light and quick work, with very satisfactory results.
LIFFORD—LIGHT

A distinctively American life-boat extensively used is the Beebe-McLellan self-bailing boat (fig. 11), which for all round life-saving work is held in the highest esteem. It possesses all the qualities of the self-righting and self-bailing life-boats in use in all life-saving institutions, except that it is self-righting. The sacrifice of this quality is largely counteracted by the ease with which it can be righted by its crew when capsized. For accomplishing this the crews are thoroughly drilled. In drill a trained crew can upset and right the boat and resume their places at the oars in twenty seconds. The boat is built of cedar, weighs about 1200 lb, and can be used at all stations and launched by the crew directly off the beach from the boat-wagon especially made for it. The self-bailing quality is secured by a water-tight deck at a level a little above the load water line with relieving tubes fitted with valves through which any water shipped runs back into the sea by gravity. Air cases along the sides under the thwart, inclining towards the middle of the boat, minimize the quantity of water taken in, and the water-ballast tank in the bottom increases the stability by the weight of the water which can be admitted by opening the valve. When transported along the land it is empty. The Beebe-McLellan boat is 25 ft long, 7 ft beam, and will carry 12 to 15 persons in addition to its crew. Some of these boats, intended for use in localities where the temperature of the water will not permit of frequent upsetting and righting drills, are built with end air cases which render them self-righting.

In addition to the principal appliances described, a number of minor importance are included in the equipment of every life-saving station, such as launching carriages for life-boats, roller boat-skids, heaving sticks and all necessary tools. Members of all life-saving crews are required on all occasions of boat practice or duty at wrecks to wear life-belts of the prescribed pattern. (A. T. T.)

Life-boat Service in other Countries.—Good work is done by the life-boat service in other countries, most of these institutions having been formed on the lines of the Royal National Life-boat Institution of Great Britain. The services are operating in the following countries:

Belgium.—Established in 1838. Supported entirely by government.

Denmark.—Established in 1848. Government service.

Sweden.—Established in 1856. Government service.

France.—Established in 1865. Voluntary association, but assisted by the government.

Germany.—Established in 1885. Supported entirely by voluntary contributions.

Turkey (Black Sea).—Established in 1868. Supported by dues.

Russia.—Established in 1872. Voluntary association, but receiving an annual grant from the government.

Italy.—Established in 1879. Voluntary association.

Spain.—Established in 1888. Voluntary association, but receiving annually a grant of 4,440 yen from government.

Canada.—Established in 1880. Government service.

Ireland.—Established in 1884. Voluntary association, but assisted by a government subsidy.

Norway.—Established in 1891. Voluntary association, but receiving a small annual grant from government.

Portugal.—Established in 1898. Voluntary society.

India (East Coast).—Voluntary association.

Australia (South).—Voluntary association.

New Zealand.—Voluntary association.

Japan.—The National Life-boat Institution of Japan was founded in 1889. It is a voluntary society, assisted by government. Its affairs are managed by a president and a vice-president, supported by a very influential council. The head office is at Tokyo; there are numerous branches with local committees. The Imperial government contributes an annual subsidy of 20,000 yen (£2000). The members of the Institution consist of three classes—honorary, ordinary and sub-ordinary, the amount contributed by the member determining the class in which he is placed. The chairman and council are not, as in Great Britain, appointed by the subscribers, but by the president, who must always be a member of the imperial family. The Institution bestows three medals: (a) the medal of merit, to be awarded to persons rendering distinguished service to the Institution; (b) the medal of membership, to be held by honorary and ordinary members or subscribers; and (c) the medal of praise, which is bestowed on those distinguishing themselves by special service in the work of rescue.

LIFFORD, the county town of Co. Donegal, Ireland, on the left bank of the Foyle. Pop. (1901) 446. The county gaol, court house and infirmary are here, but the town is practically a suburb of Strabane, across the river, in Co. Londonderry. Liford, formerly called Ballyduff, was a chief stronghold of the O'Donnells of Tyrconnell. It was incorporated as a borough (under the name of Liffer) in the reign of James I. It returned two members to the Irish parliament until the union in 1800.

LIGAMENT (Lat. ligamentum, from ligare, to bind), anything which binds or conveys two or more parts; in anatomy a piece of tissue connecting different parts of an organism (see Connective Tissues and Joints).

LIGAO, a town near the centre of the province of Albay, Luzon, Philippine Islands, close to the left bank of a tributary of the Bicol river, and on the main road through the valley. Pop. (1903) 17,687. East of the town rises Mayon, an active volcano, and the rich volcanic soil in this region produces hemp, rice and coco-nuts. Agriculture is the sole occupation of the inhabitants. Their language is Bicol.

LIGHT. Introduction.—§ 1. “Light” may be defined subjectively as the sense-impression formed by the eye. This is the most familiar connotation of the term, and suffices for the discussion of optical subjects which do not require an objective definition, and, in particular, for the treatment of physiological optics and vision. The objective definition, or the “nature of light,” is the ultima Thule of optical research. “Emission theories,” based on the supposition that light was a stream of corpuscles, were at first accepted. These gave place during the opening decades of the 19th century to the “undulatory or wave theory,” which may be regarded as culminating in the “elastic solid theory”—so named from the lines along which the mathematical investigation proceeded—and according to which light is a transverse vibratory motion propagated longitudinally through the aether. The mathematical researches of James Clerk Maxwell have led to the rejection of this theory, and it is now held that light is identical with electromagnetic disturbances, such as are generated by oscillating electric currents or moving magnets. Beyond this point we cannot go at present. To quote Arthur Schuster (Theory of Optics, 1904), “So long as the character of the displacements which constitute the waves remains undefined we cannot pretend to have established a theory of
light.” It will thus be seen that optical and electromagnetic phenomena are co-ordinated as a phase of the physics of the ‘aether,’ and that the investigation of these sciences culminates in the derivation of the properties of this conceptual medium, the existence of which was called into being as an instrument of research.1 The methods of the elastic-solid theory can still be used with advantage in treating many optical phenomena, more especially so long as we remain ignorant of fundamental matters concerning the origin of electric and magnetic strains and stresses; in addition, the treatment is more intelligible, the researches on the electromagnetic theory leading in many cases to the derivation of differential equations which express quantitative relations between diverse phenomena, although no precise meaning can be attached to the symbols employed. The school following Clerk Maxwell and Heinrich Hertz has certainly laid the foundations of a complete theory of light and electricity, but the methods must be adopted with caution, lest one be constrained to say with Ludwig Eduard Boltzmann as in the introduction to his Vorlesungen über Maxwell's Theorie der Elektricität and des Lichtes:—

"So soll ich denn mit saurem Schweiss
Euch lehren, was ich selbst nicht weiss."

Goethe, Faust.

The essential distinctions between optical and electromagnetic phenomena may be traced to differences in the lengths of light-waves and of electromagnetic waves. The aether can probably transmit waves of any wave-length, the velocity of longitudinal propagation being about $3 \times 10^8$ cms per second. The shortest waves, discovered by Schumann and accurately measured by Lyman, have a wave-length of 0.0001 mm; the ultra-violet, recognized by their action on the photographic plate or by their promoting fluorescence, have a wave-length of 0.0002 mm; the eye recognizes vibrations of a wave-length ranging from about 0.0004 mm (violet) to about 0.0007 (red); the infra-red rays, recognized by their heating power or by their action on phosphorescent bodies, have a wave-length of 0.001 mm; and the longest waves present in the radiations of a luminous source are the residual rays ("Rest-streichen") obtained by repeated reflections from quartz (0.005 mm), from fluorite (0.006 mm), and from sylvestre (0.006 mm). The research-field of optics includes the investigation of the rays which we have just enumerated. A delimitation may then be made, inasmuch as luminous sources yield no other radiations, and also since the next series of waves, the electromagnetic waves, have a minimum wave-length of 6 mm.

§ 2. The commonest subjective phenomena of light are colour and visibility, i.e. why are some bodies visible and others not, or, in other words, what is the physical significance of the words "transparency," "colour" and "visibility." What is ordinarily understood by a transparent substance is one which transmits all the rays of white light without appreciable absorption—that some absorption does occur is perceived when the substance is viewed through a sufficient thickness. Colour is due to the absorption of certain rays of the spectrum, the unabsorbed rays being transmitted to the eye, where the occasions the sensation of colour (see Colour; Absorption of Light). Transparent bodies are seen partly by reflected and partly by transmitted light, and opaque bodies by absorption. Refraction also influences visibility. Objects immersed in a liquid of the same refractive index and dispersion would be invisible; for example, a glass rod can hardly be seen when immersed in Canada balsam; other instances occur in the petrological examination of rock-sections under the microscope. In a complex rock-section the boldness with which the constituents stand out are measures of the difference between their refractive indices and the refractive index of the mounting medium, and the

1 The invention of "aethers" is to be carried back, at least, to the Greek philosophers, and with the growth of knowledge they were empirically postulated to explain many diverse phenomena. Only one "aether" has survived the ages—heliocentric light with light and electricity, and of which Lord Salisbury, in his presidential address to the British Association in 1894, said, "For more than two generations the main, if not the only, function of the word 'aether' has been to furnish a nominative case to the verb 'to undulate.'" (See AETHER.)

2 With the Greeks the word "Optics" or Οπτική (from ὀπτάμα, the obsolete present of ὁπάμω, I see) was restricted to questions concerning vision, with the eye as an optical instrument, with colour-perception, and more nearly the indices coincide the less defined become the boundaries, while the interior of the medium may be most advantageously explored. Lord Rayleigh has shown that transparent objects can only be seen when non-uniformly illuminated, the differences in the refractive indices of the substance and the surrounding medium becoming inoperative when the illumination is uniform on all sides. R. W. Wood has performed experiments which confirm this view.

The analysis of white light into the spectrum colours, and the re-formation of the original light by transmitting the spectrum through a reversed prism, proved, to the satisfaction of Newton and subsequent physicists until late in the 19th century, that the various coloured rays were present in white light, and that the action of the prism was merely to sort out the rays. This view, which suffices for the explanation of most phenomena, has now been given up, and the modern view is that the prism or grating really does manufacture the colours, as was held previously to Newton. It appears that white light is a sequence of irregular wav-trains which are analysed into series of more regular trains by the prism or grating in a manner comparable with the analytical resolution presented by Fourier's theorem. The modern view points to the mathematical existence of waves of all wave-lengths in white light, the Newtonian view to the physical existence. Strictly, the term "monochromatic" light is only applicable to light of a single wave-length (which can have no actual existence), but it is commonly used to denote light which cannot be analysed by the instruments at our disposal; for example, with low-power instruments the light emitted by sodium vapour would be regarded as homogeneous or monochromatic, but higher power instruments resolve this light into two components of different wave-lengths, each of which is of a higher degree of homogeneity, and it is not impossible that these rays may be capable of further analysis.

§ 3. Divisions of the Subject.—In the early history of the science of light or optics a twofold division was adopted: Cate

- optics (from Gr. κατά, a mirror), embracing the phenomena of reflection, i.e. the formation of images by mirrors; and Dioptrics (Gr. δαί, through), embracing the phenomena of refraction, i.e. the bending of a ray of light when passing obliquely through the surface dividing two media. A third element, Chromatics (Gr. χρώμα, colour), was subsequently introduced to include phenomena involving colour transformations, such as the iridescence of mother-of-pearl, feathers, soap-bubbles, oil floating on water, &c. This classification has been discarded (although the terms, particularly "dioptric" and "chromatic," have survived as adjectives) in favour of a twofold division: geometrical optics and physical optics.

Geometrical optics is a mathematical development (mainly effected by geometrical methods) of three laws assumed to be rigorously true: (1) the law of rectilinear propagation, viz. that light travels in straight lines or rays in any homogeneous medium; (2) the law of reflection, viz. that the incident and reflected rays at any point of a surface are equally inclined to, and coplanar with, the normal to the surface at the point of incidence; and (3) the law of refraction, viz. that when light incidents and refracted rays at a surface dividing two media make angles with the normal to the surface at the point of incidence whose sines are in a ratio (termed the "refractive index") which is constant for every particular pair of media, and that the incident and refracted rays are coplanar with the normal. Physical optics, on the other hand, has for its ultimate object the elucidation of the question: what is light? It investigates the nature of the rays themselves, and, in addition to determining the validity of the axioms of geometrical optics, embraces phenomena for the explanation of which an expansion of these assumptions is necessary.

Of the subordinate phases of the science, "physiological optics" is concerned with the phenomena of vision, with the eye as an optical instrument, with colour-perception, and
with such allied subjects as the appearance of the eyes of a cat and the luminosity of the glow-worm and fiery; “meteorological optics” includes phenomena occasioned by the atmosphere, such as the rainbow, halo, corona, mirage, twinkling of stars and colour of the sky, and also the effects of atmospheric dust in promoting such brilliant sunsets as were seen after the eruption of Krakatoa; “magneto-optics” investigates the effects of electricity and magnetism on optical properties; “photo-chemistry,” with its more practical development photography, is concerned with the influence of light in effecting chemical action; and the term “applied optics” may be used to denote, on the one hand, the experimental investigation of material for forming optical systems, e.g. the study of glasses with a view to the formation of a glass of specified optical properties (with which may be included such matters as the transparency of rock-salt for the infra-red and of quartz for the ultra-violet rays), and, on the other hand, the application of geometrical and physical investigations to the construction of optical instruments.

§ 4. Arrangement of the Subject.—The following three divisions of this article deal with: (I) the history of the science of light; (II) the nature of light; (III) the velocity of light; but a summary (which does not aim at scientific precision) may here be given to indicate to the reader the inter-relation of the various optical phenomena, those phenomena which are treated in separate articles being shown in larger type.

The simplest subjective phenomena of light are colour and intensity, the measurement of the latter being named photometry. When light falls on a medium, it may be returned by reflection or it may suffer absorption; or it may be transmitted and undergo refraction, and, if the light be composite, dispersion; or, as in the case of oil films on water, brilliant colours are seen, an effect which is due to interference. Again, if the rays be transmitted in two directions, as with certain crystals, “double refraction” (see refraction, dispersion) takes place, and the emergent rays have undergone polarization. A shadow is cast by light falling on an opaque object, the complete theory of which involves the phenomenon of diffraction. Some substances have the property of transforming luminous radiations, presenting the phenomena of fluorescence, phosphorescence, and the phosphor. An optical system is composed of any number of mirrors or lenses, or of both. If light falling on a system be not brought to a focus, i.e. if all the emergent rays be not concurrent, we are presented with a caustic and an aberration. An optical system is simply the setting up of an optical system, the telescope, microscope, objective, optical lantern, camera lucida, camera obscura and the kaleidoscope are examples; instruments serviceable for simultaneous vision with both eyes are termed binocular instruments; the stereoscope may be placed in this category; the optical action of the zoetrope, with its modern development the cinematograph, depends upon the physiological persistence of vision. Meteorological optical phenomena comprise the corona, halo, mirage, rainbow, colour of sky and twilight, and also astronomical refraction (see refraction, astronomical); the complete theory of the corona involves diffraction, and atmospheric dust also plays a part in this group of phenomena.

I. History

§ 1. There is reason to believe that the ancients were more familiar with optics than with any other branch of physics; and this may be due to the fact that for a knowledge of external things man is indebted to the sense of vision in a far greater degree than to other senses. That light travels in straight lines—or, in other words, that an object is seen in the direction in which it really lies—must have been realized in very remote times. The antiquity of mirrors points to some acquaintance with the phenomena of reflection, and Layard’s discovery of a convex lens of rock-crystal among the ruins of the palace of Nimrud implies a knowledge of the burning and magnifying powers of this instrument. The Greeks were acquainted with the fundamental law of reflection, viz. the equality of the angles of incidence and reflection; and it was Hero of Alexandria who proved that the path of the ray is the least possible. The lens, as an instrument for magnifying objects or for concentrating rays to effect combustion, was also known. Aristophanes, in the Clouds (c. 424 B.C.), mentions the use of the burning glass to destroy the writing on a waxed tablet; much later, Pliny describes such glasses as solid balls of rock-crystal or glass, or hollow glass balls filled with water, and Seneca mentions their use by engravers. A treatise on optics (Κατοπτρικά), assigned to Euclid by Proclus and Marinus, shows that the Greeks were acquainted with the production of images by plane, cylindrical and concave and convex spherical mirrors, but it is doubtful whether Euclid was the author, since neither this work nor the Οπτικά, a work treating of vision and also assigned to him by Proclus and Marinus, is mentioned by Pappus, and more particularly since the demonstrations do not exhibit the precision of his other writings.

Reflection, or catoptrics, was the key-note of their explanations of optical phenomena; it is to the reflection of solar rays by the air that Aristotle ascribed twilight, and from his observation of the colours formed by light falling on spray, he attributes the rainbow to reflection from drops of rain. Although certain elementary phenomena of refraction had also been noted—such as the apparent bending of an oar at the point where it met the water, and the apparent elevation of a coin in a basin by filling the basin with water—the quantitative law of refraction was unknown; in fact, it was not formulated until the beginning of the 17th century. The analysis of white light into the continuous spectrum of rainbow colours by transmission through a prism was observed by Seneca, who regarded the colours as fictitious, placing them in the same category as the iridescent appearance of the feathers of a pigeon’s neck.

§ 2. The aversion of the Greek thinkers to detailed experimental inquiry stultified the progress of the science; instead of acquiring facts necessary for formulating scientific laws and correcting hypotheses, the Greeks devoted their intellectual energies to philosophizing on the nature of light itself. In their search for a theory the Greeks were mainly concerned with vision—in other words, they sought to determine how an object was seen, and to what its colour was due. Emission theories, involving the conception that light was a stream of concrete particles, were formulated. The Pythagoreans assumed that vision and colour were caused by the bombardment of the eye by minute particles projected from the surface of the object seen. The Platonists subsequently introduced three elements—a stream of particles emitted by the eye (their “divine fire”), which united with the solar rays, and, after the combination had met a stream from the object, returned to the eye and excited vision.

In some form or other the emission theory—that light was a longitudinal propulsion of material particles—dominated optical thought until the beginning of the 19th century. The authority of the Platonists was strong enough to overcome Aristotle’s theory that light was an activity (εἰρήνη) of a medium which he termed the pal₄a (δανάνες); about two thousand years later Newton’s exposition of his corpuscular theory overcame the indulgent hypotheses of Descartes and Huygens; and it was only after the acquisition of new experimental facts that the labours of Thomas Young and Augustin Fresnel indubitably established the wave-theory.

§ 3. The experimental study of refraction, which had been almost entirely neglected by the early Greeks, received more attention during the opening centuries of the Christian era. Cleomedes, in his Cyclic Theory of Meteor, c. a.d. 52, alludes to the apparent bending of a stick partially immersed in water, and to the rendering visible of coins in basins by filling up with water; and also remarks that the air may refract the sun’s rays so as to render that luminary visible, although actually it may be below the horizon. The most celebrated of the early
writers on optics is the Alexandrian Ptolemy (2nd century). His writings on light are believed to be preserved in two imperfect Latin manuscripts, themselves translations from the Arabic. The subjects discussed include the nature of light and colour; the formation of images by various types of mirrors, refractions at the surface of glass and of water, with tables of the angle of refraction corresponding to given angles of incidence for rays passing from air to glass and from air to water; and also astronomical refractions, i.e. the apparent displacement of a heavenly body due to the refraction of light in its passage through the atmosphere. The authentically of these manuscripts has been contested: the Almagest contains no mention of the Optics, nor is the subject of astronomical refractions noticed, but the strongest objection, according to A. de Morgan, is the fact that their author was a poor geometrist.

§ 4. One of the results of the decadence of the Roman empire was the suppression of the academies, and few additions were made to scientific knowledge on European soil until the 13th century. Extinguished in the West, the spirit of research was kindled in the East. The accession of the Arabs to power and territory in the 7th century was followed by the acquisition of the literary stores of Greece, and during the following five centuries the Arabs, both by their preservation of existing works and by their original discoveries (which, however, were but few), took a permanent place in the history of science. Pre-eminent among Arabian scientists is Alhazen, who flourished in the 11th century. Primarily a mathematician and astronomer, he also investigated a wide range of optical phenomena. He examined the anatomy of the eye, and the functions of its several parts in promoting vision; and explained how it is that we see one object with two eyes, and then not by a single ray or beam as had been previously held, but by two cones of rays proceeding from the object, one to each eye. He attributed vision to emanations from the body seen; and on his authority the Platonic theory fell into disrepute. He also discussed the magnifying powers of lenses; and it may be that his writings on this subject inspired the subsequent invention of spectacles. Astronomical observations led to the investigation of refraction by the atmosphere, in particular, astronomical refraction; he explained the phenomenon of twilight, and showed a connexion between its duration and the height of the atmosphere. He also treated optical deceptions, both in direct vision and in vision by reflected and refracted light, including the phenomenon known as the horizontal moon, i.e. the apparent increase in the diameter of the sun or moon when near the horizon. This appearance had been explained by Ptolemy on the supposition that the diameter was actually increased by refraction, and his commentator Theon endeavoured to explain why an object appears larger when viewed under water. But actual experiment showed that the diameter did not increase. Alhazen gave the correct explanation, which, however, Friar Bacon attributes to Ptolemy. We judge of distance by comparing the angle under which an object is seen with its supposed distance, so that if two objects be seen under nearly equal angles and one be supposed to be more distant than the other, then the former will be supposed to be the larger. When near the horizon the sun or moon, conceived as very distant, are intuitively compared with terrestrial objects, and therefore appear larger than when viewed at elevations.

§ 5. While the Arabs were acting as the custodians of scientific knowledge, the institutions and civilizations of Europe were gradually crystallizing. Attacked by the Mongols and by the Crusaders, the Bagdad caliphate disappeared in the 13th century. At that period the Arabic commentaries, which had already been brought to Europe, were beginning to exert great influence on scientific thought; and it is probable that their rarity and the increasing demand for the originals and translations led to those forgeries which are of frequent occurrence in the literature of the middle ages. The first treatise on optics written in Europe was admitted by its author Vitello or Vitello, a native of Poland, to be based on the works of Ptolemy and Alhazen. It was written in about 1270, and first published in 1572, with a Latin translation of Alhazen's treatise, by F. Risner, under the title Thesaurus opticae. Its tables of refraction are more accurate than Ptolemy's; the author follows Alhazen in his investigation of lenses, but his determinations of the foci and magnifying powers of spheres are inaccurate. He attributed the twinkling of stars to refraction by moving air, and observed that the scintillation was increased by viewing through water in gentle motion; he also recognized that both reflection and refraction were instrumental in producing the rainbow, but he gave no explanation of the colours.

The Perspectiva Communis of John Pecham, archbishop of Canterbury, being no more than a collection of elementary propositions containing nothing new, we have next to consider the voluminous works of Vitello's illustrious contemporary, Roger Bacon. His writings on light, Perspectiva and Specula mathematica, are included in his Opus majus. It is conceivable that he ascribed to Bacon, and his statements concerning spectacles, the telescope, and the microscope, if not based on an experimental realization of these instruments, must be regarded as masterly conceptions of the applications of lenses. As to the nature of light, Bacon adhered to the theory that objects are rendered visible by emanations from the eye.

The history of science, and more particularly the history of inventions, constantly confronts us with the problem presented by such writings as Friar Bacon's. Rarely has it been given to one man to promote an entirely new theory or to devise an original instrument; it is more generally the case that, in the evolution of a single idea, there comes some stage which arrests our attention, and to which we assign the dignity of an "invention." Furthermore, the obscurity that surrounds the early history of spectacles, the magic lantern, the telescope and the microscope, may find a partial solution in the spirit of the middle ages. The natural philosopher who was bold enough to present to a prince a pair of spectacles or a telescope would be in imminent danger of being regarded in the eyes of the church as a powerful and dangerous magician; and it is conceivable that the maker of such an instrument would jealously guard the secret of its actual construction, however much he might advertise its potentialities.

§ 6. The awakening of Europe, which first manifested itself in Italy, England and France, was followed in the 16th century by a period of increasing intellectual activity. The need for experimental inquiry was realized, and a tendency to dispute the dogmatism of the church and to question the theories of the established schools of philosophy became apparent. In the science of optics, Italy led the way, the foremost pioneers being Franciscurc Maurolycus (1404-1575) of Messina, and Giambattista della Porta (1538-1615) of Naples. A treatise by Maurolycus entitled Photismi di Lumine et Umbra prospectus radiorum incidentium facientis (1575), contains a discussion of the measurement of the intensity of light—an early essay in photometry; the formation of circular patches of light by small holes of any shape, with a correct explanation of the phenomenon; and the optical relations of the parts of the eye, maintaining that the crystalline humour acts as a lens which focuses images on the retina, explaining short- and long-sight (myopia and hypermetropia), with the suggestion that the former may be corrected by concave, and the latter by convex, lenses. He observed the spherical aberration due to elements beyond the axis of a lens, and also the caustics of refraction (diacoustics) by a sphere (seen as the bright boundaries of the luminous patches formed by receiving the transmitted light on a screen), which he correctly

1 It seems probable that spectacles were in use towards the end of the 13th century. The Italian dictionary of the Accademia della Crusca (1612) mentions a sermon of Jordan de Rivalto, published in 1395, which refers to the invention as "not twenty years since"; and in 1317, bears an inscription assigning the invention to him. (See the articles Telescope and Camera Obscura for the history of these instruments.)
regarded as determined by the intersections of the refracted rays. His researches on refraction were less fruitful; he assumed the angles of incidence and refraction to be in the constant ratio of 8 to 5, and the rainbow, in which he recognized four colours, orange, green, blue, and purple, to be formed by rays reflected in the drops along the sides of an octagon. Porta's fame rests chiefly on his *Magia naturalis sive de miraculis rerum naturalium*, of which four books were published in 1538, the complete work of twenty books appearing in 1589. It attained great popularity, perhaps by reason of its astonishing medley of subjects—pyrotechnics and perfumery, animal reproduction and hunting, alchemy and optics—and it was several times reprinted, and translated into English (with the title *Natural Magic*, 1658). German, French, Spanish, Hebrew and Arabic. The work contains an account of the camera obscura, with the invention of which the author has sometimes been credited; but, whoever the inventor, Porta was undoubtedly responsible for improving and popularizing that instrument, and also the magic lantern. In the same work practical applications of lenses are suggested, combinations comparable with telescopes are vaguely treated, and spectacles are discussed. His *De Refractione, optices parte* (1593) contains an account of binocular vision, in which are found indications of the principle of the stereoscope.

§ 7. The empirical study of lenses led, in the opening decade of the 17th century, to the emergence of the telescope from its former obscurity. The first form, known as the Dutch or Galileo telescope, consisted of a convex and a concave lens, a combination which gave erect images; the later form, now known as the "Keplerian" or "astronomical" telescope (in contrast with the earlier or "terrestrial" telescope) consisted of two convex lenses, which gave inverted images. With the microscope, too, advances were made, and it seems probable that the compound type came into common use about this time. These single instruments were followed by the invention of binoculars, i.e. instruments which permitted simultaneous vision with both eyes. The most notable was Kepler's, in which he doubt that the experimental realization of the telescope, opening up as it did such immense fields for astronomical research, stimulated the study of lenses and optical systems. The investigations of Maurolycus were insufficient to explain the theory of the telescope, and it was Kepler who first determined the principle of the Galilean telescope in his *Dieoptica* (1611), which also contains the first description of the astronomical or Keplerian telescope, and the demonstration that rays parallel to the axis of a plano-convex lens come to a focus at a point on the axis, provided that the index of refraction of the medium is greater than that of the lens. The true law—"that the ratio of the sines of the angles of incidence and refraction is constant"—was discovered in 1627 by Willebrord Snell (1591-1626); but was published for the first time after his death, and with no mention of his name, by Descartes. Whereas in Snell's manuscript the law was stated in the form of the ratio of certain lines, trigonometrically interpretable as a ratio of cosecants, Descartes expressed the law in his modern trigonometrical form, viz. as the ratio of the sines. It may be observed that the modern form was independently obtained by James Gregory and published in his *Optica promota* (1663). Armed with the law of refraction, Descartes determined the geometrical theory of the primary and secondary rainbows, and it led him to the explanation of the various bow by Anthony de Dominis in 1611; and, similarly, in his additions to the knowledge of the telescope the influence of Galileo is not recorded.

§ 8. In his metaphysical speculations on the system of nature, Descartes formulated a theory of light at variance with the generally accepted emission theory and showing some resemblance to the earlier views of Aristotle, and, in a smaller measure, to the modern undulatory theory. He imagined light to be a pleasure transmitted by an infinitely elastic medium which pervades space, and colour to be due to rotary motions of the particles of this medium. He attempted a mechanical explanation of the law of refraction, and came to the conclusion that light passed more readily through a more highly refractive medium. This view was combated by Pierre de Fermat (1601-1655), who, from the principle known as the "law of least time," deduced the converse to be the case, i.e. that the velocity varied inversely with the refractive index. In brief, Fermat's argument was as follows: Since nature performs her operations by the most direct routes or shortest paths, then the path of a ray of light between any two points must be such that the time occupied in the passage is a minimum. The rectilinear propagation and the law of reflection obviously agree with this principle, and it remained to be proved whether the law of refraction tallied.

Although Fermat's premiss is useless, his inference is invaluable, and the most notable application of it was made in about 1824 by Sir William Rowan Hamilton, who merged it into his conception of the "characteristic function," by the help of which all optical problems, whether on the corpuscular or on the undulatory theory, are solved by one common process. Hamilton was in possession of the germs of this grand theory some years before 1824, but it was first communicated to the Royal Irish Academy in that year, and published in imperfect instalments some years later. The following is his own description of it. It is of interest as exhibiting the origin of Fermat's deduction, its relation to contemporary and subsequent knowledge, and its connexion with other analytical principles. Moreover, it is important as showing Hamilton's views on a very singular part of the more modern history of the science to which he contributed so much.

Those who have meditated on the beauty and utility, in theoretical mechanics, of the general method of Lagrange, who have felt the power and dignity of that central dynamical theorem which he deduced, in the *Mécanique analytique*... must feel that mathematical optics can only then attain a coordinate rank with mathematical mechanics, that it shall call the name of Lagrangian method, and be the unfolding of a central idea. It appears that if a general method in deductive optics can be attained at all, it must flow from some law or principle, itself of the highest generality, and of prime importance, and this law must be the principle, or law, called usually the Law of Least Action; suggested by questionable views, but established on the widest induction, and embracing every known combination of media, rays and reflections, and the most imperfect rays. This is a statement of the principle of least time, in short, that the value of the action, along which light (whatever light may be) extends its influence successively in space and time; namely, that this linear path of light, from one point to another, is always found to be such that, if it be considered as a line in space and time, it is such a line as, and in geometry the same two points might be connected, a certain integral or sum, called often *Action*, and depending by fixed rules on the length, and size, and position of the path, and on the media through which it is traversed by it, is less than all the similar integrals for the other neighboring lines, or, at least, possesses, with respect to them, a certain *stationary* property. From this Law, then, which may, perhaps, be named the Law of STATIONARY Action, it seems that many most important problems of the properties of light, which seems to offer naturally a method such as we are seeking; the one law being as it were the last step in the ascending scale of induction, respecting linear paths of light, while the other law may usually be made the first in the descending and deductive way.

"The former law of these two, that was discovered by Snell (or Laplace to Ptolemy), that, in the case of a plane mirror, the bent line formed by the incident and reflected rays is shorter than any other bent line having the same extremities, and having its point of bending on the mirror in this case and in others, is the best instances and results of the simplicity and economy of nature; and Fermat, whose researches on maxima and minima are claimed by the Continental mathematicians as the germ of the differential calculus, sought anxiously to trace some similar economy in the
more complex case of refraction. He believed that by a metaphysical or cosmological necessity, arising from the simplicity of the universe, light always takes the course which it can traverse in the shortest time. To reconcile this metaphysical opinion with the law of refraction, he supposed that the velocity of light is diminished on entering denser media in which it is observed to approach the perpendicular; for Fermat believed that the time of propagation of light along a line bent by refraction was represented by the sum of the two products, of the incident portions multiplied by the index of the first medium and of the refracted portion multiplied by the index of the second medium; because he found, by his mathematical method, that this sum was less, in the case of the transition, than in the case of the direct propagation by an actual path from one given point to another; and because he perceived that the supposition of a velocity inversely as the index reconciled his mathematical discovery of the minimum of the foregoing sort with his cosmological principle of least time. Descartes attacked Fermat's opinions respecting light, but Leibnitz zealously defended them; and Huygens was led, by reasonings of a very different kind, to adopt Fermat's conclusions of a velocity inversely as the index, and of a minimum time of propagation of light, in passing from one given point to another through an ordinary refracting plane. Newton, however, by his theory of emission and attraction, was led to conclude that the velocity of light was directly, not inversely, as the index, and that it was increased instead of being diminished on entering a denser medium; a result incompatible with the theorem of the shortest time in refraction. This theorem of shortest time was accordingly abandoned by many, and among the few who maintained it, Huygens was perhaps the first to try to reconcile it with this new fundamental principle of its science, by a new cosmological principle, that the celebrated law of least action which has since acquired so high a rank in mathematical physics, by the improvements of Euler and Lagrange."

§ 9. The second half of the 17th century witnessed developments in the practice and theory of optics which equal in importance the mathematical, chemical and astronomical acquisitions of the period. Original observations were made which led to the discovery, in an embryonic form, of new properties of light, and the development of mathematical analysis facilitated the quantitative and theoretical investigation of these properties. Indeed, mathematical and physical optics may justly be dated from this time. The phenomenon of diffraction, so named by Grimaldi, and by Newton refraction, which may be described briefly as the spreading out, or deviation, from the strictly rectilinear path of light passing through a small aperture or beyond the edge of an opaque object, was discovered by the Italian Jesuit, Francis Maria Grimaldi (1650-1665), and published in his Physico-Mathesis de Lumine (1665), and at the same time Newton made his classical investigation of the spectrum or the band of colours formed when light is transmitted through a prism, and studied interference phenomena in the form of the colours of thin and thick plates, and in the form now termed Newton's rings; double refraction, in the form of the dual images of a single object formed by a rhomb of Iceland spar, was discovered by Bartholinus in 1670; Huygens' examination of the transmitted beams led to the discovery of an absence of symmetry now called polarization; and the finite velocity of light was deduced in 1676 by Ole Roemer from the comparison of the observed and computed times of the eclipses of the moons of Jupiter.

These discoveries had a far-reaching influence upon the theoretical views which had been previously held: for instance, Newton's recombination of the spectrum by means of a second (inverted) prism caused the rejection of the earlier view that the prism actually manufactured the colours, and led to the acceptance of the idea that the colours were physically present in the white light, the function of the prism being merely to separate the physical mixture; and Roemer's discovery of the finite velocity of light introduced the necessity of considering the momentum of the particles which, on the accepted emission theory, composed the light. Of greater moment was the controversy concerning the emission or corpuscular theory championed by Newton and the undulatory theory presented by Huygens (see section II. of this article). In order to explain the colours of thin plates Newton was forced to abandon some of the original simplicity of his theory; and we may observe that by postulating certain motions for the Newtonian corpuscles all the phenomena of light can be explained, these motions aggregating to a transverse displacement translated longitudinally, and the corpuscles, at the same time, becoming otiose and being replaced by a medium in which the vibration is transmitted. In this way the Newtonian theory may be merged into the undulatory theory. Newton's results are collected in his Opticks, the first edition of which appeared in 1704. Huygens published his theory in his Traité de lumière (1690), where he explained reflection, refraction and double refraction, but did not elucidate the formation of shadows (which was readily explainable on the Newtonian hypothesis) or polarization, and it was this inability to explain polarization which led to Newton's rejection of the wave theory. The authority of Newton and his masterly exposition of the corpuscular theory sustained that theory until the beginning of the 19th century, when it succumbed to the assiduous skill of Young and Fresnel.

§ 10. Simultaneously with this remarkable development of theoretical and experimental optics, notable progress was made in the construction of optical instruments. The increased demand for telescopes, occasioned by the interest in observational astronomy, led to improvements in the grinding of lenses (the primary aim being to obtain forms in which spherical aberration was a minimum), and also to the study of achromatism, the principles of which followed from Newton's analysis and synthesis of white light. Kepler's supposition that lenses having the form of surfaces of revolution of the conic sections would bring rays to a focus without spherical aberration was investigated by Descartes, and the success of the latter's demonstration led to the grinding of ellipsoidal and hyperboloidal lenses, but with disappointing results. The grinding of spherical lenses was greatly improved by Huygens, who also attempted to reduce chromatic aberration in the refracting telescope by introducing a stop (i.e. by restricting the aperture of the rays); to the same experimenter are due compound eye-pieces, the invention of which had been previously suggested by Eustachio Divini. The so-called Huygenian eye-piece is composed of two plano-convex lenses with their plane faces towards the eye; the field-glass has a focal length three times that of the eye-glass, and the distance between them is twice the focal length of the eye-glass. Huygens observed that spherical aberration was diminished by making the deviations of the rays at the two lenses equal, and Ruggiero Giuseppe Boscovich subsequently pointed out that the combination was achromat. The true development, however, of the achromatic refracting telescope, which followed from the introduction of compound object-glasses giving no dispersion, dates from about the middle of the 19th century.

1 Newton's observation that a second refraction did not change the colours had been anticipated in 1648 by Marci de Kromland (1610-1667), professor of medicine at the university of Prague, in his Thesaurus, who studied the spectrum under the name of Iris triguna. There is no evidence that Newton knew of this, although he mentions de Dominic's experiment with the glass globe containing water.
The difficulty of obtaining lens systems in which aberrations were minimized, and the theory of Newton that colour production invariably attended refraction, led to the manufacture of improved specula which permitted the introduction of reflecting telescopes. The idea of this type of instrument had apparently occurred to Marin Merseus in about 1640, but the first reflector of note was described in 1663 by James Gregory in his Optica promota; a second type was invented by Newton, and a third in 1672 by Cassgrain. Slight improvements were made in the microscope, although the achromatic type did not appear until about 1820, some sixty years after John Dollond had determined the principle of the achromatic telescope (see Aberation, Telescope, Microscope, Binocular Instrument).

§ 11. Passing over the discovery by Ehrenfried Walther Tschirnhausen (1651-1708) of the caustics produced by reflection ("cautacustis") and his experiments with large reflectors and refractors (for the manufacture of which he established glassworks in Italy); James Bradley's discovery in 1728 of the "aberration of light," with the subsequent derivation of the velocity of light, the value agreeing fairly well with Roemer's estimate; the foundation of scientific physics by interference developed by Laplace in an essay of 1770 and expanded in 1780 into Traité d'optique sur la gradation de la lumière; the publication of John Henry Lambert's treatise on the same subject, entitled Photometrica, sive de Mensura et Gradibus Luminis, Colorum et Umbrae (1760); and the development of the telescope and other optical instruments, we arrive at the closing decades of the 18th century. During the forty years 1780 to 1820 the history of optics is especially marked by the names of Thomas Young and Augustin Fresnel, and in a lesser degree by Arago, Malus, Sir William Herschel, Fraunhofer, Wollaston, Biot and Brewster.

Although the corpuscular theory had been disputed by Benjamin Franklin, Leonhard Euler and others, the authority of Newton retained for it an almost general acceptance until the beginning of the 19th century, when Young and Fresnel instituted their destructive criticism. Basing his views on the earlier undulatory theories and diffraction phenomena of Grimaldi and Hooke, Young accepted the Huyggenian theory, assuming, from a false analogy with sound waves, that the waves were transverse, and that the direction of the vibration might be transverse, i.e. at right angles to the direction of the rays. As with Huygens, Young was unable to explain diffraction correctly, or polarization. But the assumption enabled him to establish the principle of interference, one of the most fertile in the science of physical optics. The undulatory theory was also accepted by Fresnel who, perceiving the inadequacy of the researches of Huygens and Young, showed in 1818 by an analysis which, however, is not quite free from objection, that, by assuming that every element of a wave-surface could act as a source of secondary waves or wavelets, the diffraction bands were due to the interference of the secondary waves formed by each element of a primary wave falling upon the edge of an obstacle or aperture. One consequence of Fresnel's theory was that the bands were independent of the nature of the diffracting edge—a fact confirmed by experiment and therefore invalidating Young's theory that the bands were produced by the interference between the primary wave and the wave reflected from the edge of the obstacle. Another consequence, which was first mathematically deduced by Poisson and subsequently confirmed by experiment, is the paradoxical phenomenon that a small circular disk illuminated by a point source casts a shadow having a bright centre.

§ 12. The undulatory theory reached its zenith when Fresnel explained the complex phenomena of polarization, by adopting the conception of Hooke that the vibrations were transverse, and not longitudinal. Polarization by double refraction had been investigated by Huygens, and the researches of Wollaston and, more especially, of Young, gave such an impetus to the study that the Institute of France made double refraction the subject of a prize essay in 1812. E. L. Malus (1775-1812) discovered the phenomenon of polarization by reflection about 1808 and investigated metallic reflection; Arago discovered circular polarization in quartz in 1811, and, with Fresnel, made many experimental investigations, which aided the establishment of the Fresnel-Arago laws of the interference of polarized beams; Biot introduced a reflecting polariscope, investigated the colours of crystalline plates and made many careful researches on the rotation of the plane of polarization; Sir David Brewster made investigations over a wide range, and formulated the law connecting the angle of polarization with the refractive index of the reflecting medium. Fresnel's theory was developed in a strikingly original manner by Sir William Rowan Hamilton, who interpreted from Fresnel's analytical determination of the geometrical form of the wave-surface in biaxial crystals the existence of two hitherto unrecorded phenomena. At Hamilton's instigation Humphry Lloyd undertook the experimental search, and brought to light the phenomena of external and internal conical refraction.

The undulatory vibration postulated by Fresnel having been generally accepted as explaining most optical phenomena, it became necessary to determine the mechanical properties of the ether which transmits this motion. Fresnel, Neumann, Cauchy, MacCullagh, and, especially, Green and Stokes, developed the "elastic-solid theory." By applying the theory of elasticity they endeavoured to determine the constants of a medium which could transmit waves of the nature of light. Many different allocations were suggested (of which one of the most recent is Lord Kelvin's "contractile aether," which, however, was afterwards discarded by its author), and the theory as left by Green and Stokes has merits other than purely historical. At a later date theories involving an action between the aether and material atoms were proposed, the first of any moment being J. Boussinesq's (1867). C. Christiansen's investigation of anomalous dispersion in 1870, and the failure of Cauchy's formula (founded on the elastic-solid theory) to explain this phenomenon, led to the theories of W. Schmidt (1872), H. von Helmholtz (1878), E. Ketteler (1878), B. Lorentz (1878) and W. Voigt (1883). A third class of theory, to which the present-day theory belongs, followed from Clerk Maxwell's analytical investigations in electromagnetics. Of the greatest exponents of this theory we may mention H. A. Lorentz, P. Drude and J. Larmor, while Lord Rayleigh has, with conspicuous brilliancy, explained several phenomena (e.g. the colour of the sky) on this hypothesis. For a critical examination of these theories see section II. of this article; reference may also be made to the British Association Reports: "On Physical Optics," by Humphry Lloyd (1834), p. 230; "On Double Refraction," by Sir G. G. Stokes (1862), p. 281; "On Optical Theories," by R. T. Glazebrook (1885), p. 157.

§ 13. Recent Developments.—The determination of the velocity of light (see section III. of this article) may be regarded as definitely settled, a result contributed to by A. H. L. Fizeau (1840), J. B. L. Foucault (1850, 1862), A. Cornu (1874), A. A. Michelson (1880), James Young and George Forbes (1882), Simon Newcomb (1880-1882) and Cornu (1900). The velocity in moving media was investigated theoretically by Fresnel; and Fizeau (1850), and Michelson and Morley (1886) showed experimentally that the velocity was increased in running water by an amount agreeing with Fresnel's formula, which was based on the hypothesis of a stationary aether. The optics of moving media have also been investigated by Lord Rayleigh, and more especially by H. A. Lorentz, who also assumed a stationary aether. The relative motion of the earth and the aether has an...
The introduction of the phenomenon of the aberration of light, and has been treated with mastery skil by Joseph Larmor and others (see Aether). The relation of the earth's motion to the intensities of terrestrial sources of light was investigated theoretically by Fizeau, but no experimental inquiry was made until 1903, when Nordmeyer obtained negative results, which were confirmed by the theoretical investigations of A. A. Bucherer and H. A. Lorentz.

Experimental photometry has been greatly developed since the pioneer work of Bouguer and Lambert and the subsequent introduction of the photometers of Richè, Rumford, Bunsen and Wheatstone, followed by Swan's in 1859, and O. R. Lumnmer and E. Brodhun's instrument (essentially the same as Swan's) in 1889. This expansion may largely be attributed to the increase in the number of artificial illuminants—especially the many types of filament- and arc-electric lights, and the incandescent gas light. Colour photometry has also been notably developed, especially since the enunciation of the "Purkinje phenomenon" in 1825. Sir William Abney has contributed much to this subject, and A. M. Meyer has designed a photometer in which advantage is taken of the phenomenon of contrast colours. "Flicker photometry" may be dated from O. N. Rood's investigations in 1893, and the same principle has been applied by Haycraft and Whitman. These questions—colour and flicker photometry—have important affinities to colour perception and the persistence of vision (see Vision). The spectrophotometer, devised by De Witt Bristol Brace in 1899, which permits the comparison of similarly coloured portions of the spectra from two different sources, has done much valuable work in the determination of absorptive powers and extinction coefficients. Much attention has also been given to the preparation of a standard of intensity, and many different sources have been introduced (see Photometry). Stellar photometry, which was first investigated instrumentally with success by Sir John Herschel, was greatly improved by the introduction of Zöllner's photometer, E. C. Pickering's meridian photometer and C. Pritchard's wedge photometer. Other methods of research in this field are by photography—photographic photometry—and radiometric method (see Photometry, Celestial).

The earlier methods for the experimental determination of refractive indices by measuring the deviation through a solid prism of the substance in question or, in the case of liquids, through a hollow prism containing the liquid, have been replaced in most accurate work by other methods. The method of total reflection, due originally to Wollaston, has been put into a very convenient form, applicable to both solids and liquids, in the work of Lord Rayleigh. Stellar photometry (see Radiometric method, based on interference phenomena, have been devised. Jamin's interference refractometer is one of the earlier forms of such apparatus; and Michelson's interferometer is one of the best of later types (see Interference). The variation of the refractive index with density has been the subject of much experimental and theoretical inquiry. The empirical rule of Gladstone and Dale was often at variance with experiment, and the mathematical investigations of H. A. Lorentz of Leiden and L. Lorenz of Copenhagen on the electromagnetic theory led to a more consistent formula. The experimental work has been chiefly associated with the names of H. H. Landolt and J. W. Brühl, whose results, in addition to verifying the Lorenz-Lorentz formula, have established that this function of the refractive index and density is a colligative property of the molecule, i.e., it is calculable additively from the values of this function for the component atoms, allowance being made for the mode in which they are mutually combined (see Chemistry, Physical).

The preparation of lenses, in which the refractive index decreases with the distance from the axis, by K. F. J. Exner, H. F. L. Matthiessen and Schott, and the curious results of refraction by non-homogeneous media, as realized by R. Wood may be mentioned (see Mirror).

The spectrum of white light produced by prismatic refraction has engaged many investigators. The infra-red or heat waves were discovered by Sir William Herschel, and experiments on the actinic effects of the different parts of the spectrum on silver salts by Scheele, Senebier, Ritter, Seebeck and others, proved the increased activity as one passed from the red to the violet and the ultra-violet. Wollaston also made many investigations in this field, noticing the dark lines—"Fraunhofer lines"—which cross the solar spectrum, which were further discussed by Brewster and Fraunhofer, who thereby laid the foundations of modern spectroscopy. Mention may also be made of the investigations of Lord Rayleigh and Arthur Schuster on the resolving power of prisms (see Diffraction), and of the modern view of the function of the prism in analysing white light. The infra-red and ultra-violet rays are of especial interest since, although not affecting vision after the manner of ordinary light, they possess very remarkable properties. Theoretical investigation on the undulatory theory of the law of reflection shows that a surface, too rough to give any trace of regular reflection with ordinary light, may regularly reflect the long waves, a phenomenon experimentally realized by Lord Rayleigh. Long waves—the so-called "residual rays" or "Rest-strahlen"—have also been isolated by repeated reflections from quartz surfaces of the light from zirconia raised to incandescence by the oxyhydrogen flame (E. F. Nichols and H. Rubens); far longer waves were isolated by similar reflections from fluorate (60 μ) and sylvite (61 μ) surfaces in 1859 by Rubens and E. Aschkinass. The short waves—ultra-violet rays—have also been studied, the researches of E. F. Nichols on the transparency of quartz to these rays, which are especially present in the radiations of the mercury arc, having led to the introduction of lamps made of fused quartz, thus permitting the convenient study of these rays, which, it is to be noted, are absorbed by ordinary clear glass. Recent researches at the works of Schott and Genossen, Jena, however, have resulted in the production of a glass transparent to the ultra-violet.

Dispersion, i.e., that property of a substance which consists in having a different refractive index for rays of different wave-lengths, was first studied in the form known as "ordinary dispersion" in which the refrangibility of the ray increased with the wave-length. Cases had been observed by Fox Talbot, Le Roux, and especially by Christiansen (1870) and A. Kundt (1871-1872) where this normal rule did not hold; to such phenomena the name "anomalous dispersion" was given, but really there is nothing anomalous about it at all, ordinary dispersion being merely a particular case of the general phenomenon. The Cauchy formula, which was founded on the elastic-solid theory, did not agree with the experimental facts, and the germs of the modern theory, as was pointed out by Lord Rayleigh and Lord Rayleigh, has been formed, the experiments being used for the Mathematical Tripos examination for 1860. The principle, which occurred simultaneously to W. Sellmeier (who is regarded as the founder of the modern theory) and had been employed about 1850 by Sir G. G. Stokes to explain absorption lines, involves an action between the aether and the molecules of the dispersing substance. The mathematical investigation is associated with the names of Sellmeier, Hermann Helmholtz, Eduard Ketteler, P. Drude, H. A. Lorentz and Lord Rayleigh, and the experimental side with many observers—F. Pachen, Rubens and others; absorbing media have been investigated by A. W. Phüger, a great many asphalt dyed by K. Stöckl, and sodium vapour by R. W. Wood. Mention may also be made of the beautiful experiments of Christiansen (1884) and Lord Rayleigh on the colours transmitted by white powders suspended in liquids of the same refractive index. If, for instance, benzol be gradually added to finely powdered quartz, a succession of beautiful colours—red, yellow, green and finally blue—is transmitted, or, under certain conditions, the colours may appear at once, causing the mixture to flash like a fiery opal. Absorption, too, has received much attention; the theory has been especially elaborated by M. Planck, and the experimental investigation has been prosecuted from the purely physical standpoint, and also from the standpoint of the physical chemist, with a view to correlating absorption with constitution.

Interference phenomena have been assiduously studied. The
experiments of Young, Fresnel, Lloyd, Fizeau and Foucault, of Fresnel and Arago on the measurement of refractive indices by the interference bands, of H. F. Talbot on the "Talbot bands" (which he insufficiently explained on the principle of interference, it being shown by Sir G. B. Airy that diffraction phenomena supervene), of Baden-Powell on the "Powell bands," of David Brewster on "Brewster's bands," have been developed, together with many other phenomena—Newton's rings, the colours of thin, thick and mixed plates, &c.—in a striking manner, one of the most important results being the construction of interferometers applicable to the determination of refractive indices and wave-lengths, with which the names of Jamin, Michelson, Fabry and Perot, and of Lummer and E. Gehrke are chiefly associated. The mathematical investigations of Fresnel may be regarded as being completed by the analysis chiefly due to Airy, Stokes and Lord Rayleigh. Mention may be made of Sir G. G. Stokes' attribution of the colours of iridescent crystals to periodic twinning; this view has been confirmed by Lord Rayleigh (Phil. Mag., 1887, vol. 3) from the purity of the reflected light, concluded that the laminae were equidistant by the order of a wave-length. Prior to 1801 only interference between waves proceeding in the same direction had been studied. In that year Otto H. Wiener obtained, on a film \( \frac{1}{5} \)th of a wave-length in thickness, photographic impressions of the stationary waves formed by the interference of waves proceeding in opposite directions, and in 1802 Drude and Nernst employed a fluorescent film to record the same phenomenon. This principle is applied in the Lippmann colour photography, which was suggested by W. Zener, realized by Gabriel Lippmann, and further investigated by R. G. Neuhaus, O. H. Wiener, H. Lehmann and others.

Great progress has been made in the study of diffraction, and "this department of optics is precisely the one in which the wave theory has secured its greatest triumphs" (Lord Rayleigh). The mathematical investigations of Fresnel and Poisson were placed on a dynamical basis by Sir G. G. Stokes; the interference phenomena were explained by the introduction of "Babinet's principle" in 1837, and Cornu's graphic methods in 1874. The theory also gained by the researches of Fraunhofer, Airy, Schwert, E. Lommel and others. The theory of the concave grating, which resulted from H. A. Rowland's classical methods of ruling lines of the necessary nature and number on curved surfaces, was worked out by Rowland, E. Mascart, C. Runge and others. The resolving power and the intensity of the spectra have been treated by Lord Rayleigh and Arthur Schuster, and more recently (1903), the distribution of light has been treated by A. B. Porter. The theory of diffraction is of great importance in designing optical instruments, the theory of which has been more especially treated by Ernst Abbe (whose theory of microscopic vision dates from about 1870) by the scientific staff at the Zeiss works, Jenat, by Rayleigh and others. The theory of coronae (as diffraction phenomena) was originally due to Young, who, from the principle involved, devised the method of testing the dispersions of very small objects; and Sir G. G. Stokes subsequently explained the appearances presented by minute opaque particles borne on a transparent plate. The polarization of the light diffraction at a slit was noted in 1861 by Fizeau, whose researches were extended in 1892 by H. Du Bois, and, for the case of gratings, by Du Bois and Rubens in 1904. The diffraction of light by small particles was studied in the form of very fine chemical precipitates by John Tyndall, who noticed the polarization of the beautiful cerulean blue which was transmitted. This subject—one form of which is presented in the blue colour of the sky—has been most auspiciously treated by Lord Rayleigh on both the elastic-solid and electromagnetic theories. Mention may be made of R. W. Wood's experiments on thin metal films which, under certain conditions, originate colour phenomena inexplicable by interference and diffraction. These colours have been assigned to the principle of optical resonance, and have been treated by Kossonogov (Phys. Zelt., 1903). J. C. Maxwell Garnett (Phil. Trans. vol. 203) has shown that the colours of coloured glasses are due to ultra-microscopic particles, which have been directly studied by H. Siedentopf and R. Zsigmondy under limiting oblique illumination.

Polarization phenomena may, with great justification, be regarded as the most engrossing subject of optical research during the 19th century; the assiduity with which it was cultivated in the opening decades of that century received a great stimulus when James Nicol devised in 1828 the famous "Nicol prism," which greatly facilitated the determination of the plane of vibration of polarized light, and the facts that light is polarized by reflection, repeated refractions, double refraction and by diffraction also contributed to the interest which the subject excited. The rotation of the plane of polarization by quartz was discovered in 1811 by Arago; if white light be used the colours change as the Nicol rotates—a phenomenon termed by Biot "rotatory dispersion." Fresnel regarded rotatory polarization as compounded from right- and left-handed (dextro- and laevo-) circular polarizations; and Fresnel, Cornu, Dave and Cotton effected their experimental determination. Legrand des Cloizeaux discovered the enormously enhanced rotatory polarization of cinnabar, a property also possessed—but in a lesser degree—by the sulphates of strychnine and ethylene dimine. The rotatory power of certain liquids was discovered by Biot in 1815; and at a later date it was found that many solutions behaved similarly. A. Schuster distinguishes substances with regard to their action on polarized light as follows: substances which act in the isotropic state are termed phototropic; if the rotation be associated with crystal structure, crystalllographic; if the rotation be due to a magnetic field, magnetotropic; for cases not hitherto included the term allotropic is employed, while optically inactive substances are called isotypic. The theory of phototropic and crystalllographic rotation has been worked out on the elastic-solid (MacCullagh and others) and on the electromagnetic hypotheses (P. Drude, Cotton, &c.). Allory isism is due to the symmetry of the molecule, and is a subject of the greatest importance in modern (and, more especially, organic) chemistry (see STEREOISOMERISM).

The optical properties of metals have been the subject of much experimental and theoretical inquiry. The explanations of MacCullagh and Cauchy were followed by those of Beer, Eisenlohr, Lundquist, Ketteler and others; the refractive indices were determined both directly (by Kundt) and indirectly by means of Brewster's law; and the reflecting powers from \( \lambda = 251 \mu \) to \( \lambda = 1500 \mu \) were determined in 1900-1902 by Rubens and Hagen. The correlation of the optical and electrical constants of many metals has been especially studied by P. Drude (1900) and by Rubens and Hagen (1903).

The transformations of luminous radiations have also been studied. John Tyndall discovered calorescence. Fluorescence was treated by John Herschel in 1845, and by David Brewster in 1846, the theory being due to Sir G. G. Stokes (1852). More recent studies have been made by Lommel, E. L. Nichols and Merritt (Phys. Rev., 1906), and by Millikan who discovered polarized fluorescence in 1895. Our knowledge of phosphorescence was greatly improved by Becquerel, and Sir James Dewar obtained interesting results in the course of his low temperature researches (see LIQUID GASES). In the theoretical and experimental study of radiation enormous progress has been recorded. The pressure of radiation, the necessity of which was demonstrated by Clerk Maxwell on the electromagnetic theory, and, in a simpler manner, by Joseph Larmor in his article RADIATION in these volumes, has been experimentally determined by E. F. Nichols and Hull, and the tangential component by J. H. Poynting. With the theoretical and practical investigation the names of Balfour Stewart, Kirchhoff, Stefan, Bartoli, Boltzmann, W. Wien and Larmor are chiefly associated. Magneto-optics, too, has been greatly developed since Faraday's discovery of the rotation of the plane of polarization by the magnetic field. The rotation for many substances was measured by Sir William H. Perkin, who attempted a correlation between rotation and composition. Brace effected the analysis of the beam into its two circularly polarized
components, and in 1904 Mills measured their velocities. The Kerr effect, discovered in 1877, and the Zeeman effect (1896) widened the field of research, which, from its intimate connexion with the nature of light and electromagnetics, has resulted in discoveries of the greatest importance.

§ 14. Optical Instruments.—Important developments have been made in the construction and applications of optical instruments. To these three factors have contributed. The mathematician has quantitatively analysed the phenomena observed by the physicist, and has inductively shown what results are to be expected from certain optical systems. A consequence of this was the detailed study, and also the preparation, of glasses of diverse properties; to this the chemist largely contributed, and the manufacture of the so-called optical glass (see Glass) is possibly the most scientific department of glass manufacture. The mathematical investigations were much to Gauss, Helmholtz and others, but far more to Abbe, who introduced the method of studying the aberrations separately, and applied his results with conspicuous skill to the construction of optical systems. The development of Abbe’s methods constitutes the main subject of research of the present day, and has brought about the production of telescopes, microscopes, photographic lenses and other optical apparatus to an unprecedented pitch of excellence. Great improvements have been effected in the stereoscope. Binocular instruments with enhanced stereoscopic vision, an effect achieved by increasing the distance between the object glasses, have been introduced. In the study of diffraction phenomena, which led to the technical preparation of gratings, the early attempts of Fraunhofer, Nobert and Lewis Morris Rutherford, were followed by H. A. Rowland’s ruling of plates and concave gratings which revolutionized spectroscopic research, and, in 1888, by Michelson’s invention of the echelon grating. Of great importance are interferometers, which permit extremely accurate determinations of refractive indices and wave-lengths, and Michelson, from his classical evaluation of the standard metre in terms of the wave-lengths of certain of the cadmium rays, has suggested the adoption of the wave-length of one such ray as a standard with which national standards of length should be compared. Polarization phenomena, and particularly the rotation of the plane of polarization by such substances as sugar solutions, have led to the invention and improvements of polarimeters. The polarized light employed in such instruments is invariably obtained by transmission through a fixed Nicol prism—the polarizer—and the deviation is measured by the rotation of a second revolving Nicol the analyzer. These instruments were improved “light and shade” polarimeters, have been generally replaced by “half-shade” instruments. Mention may also be made of the microscopic examination of objects in polarized light, the importance of which as a method of crystallographic and petrological research was suggested by Nicol, developed by Sorby and greatly expanded by Zirkel, Rosenthal and others.

BIBLIOGRAPHY.—There are numerous text-books which give elementary expositions of light and optical phenomena. More advanced works, which deal with the subject experimentally and mathematically, are A. B. Bassett, Treatise on Physical Optics (1898); T. F. Higdon, Mathematical Theory of Optics (1901); R. W. Wood, Physical Optics (1905), which contains expositions on the electromagnetic theory, and treats “dispersion” in great detail. Treatises more particularly theoretical are James Walker, Analytical Theory of Light (1904); A. Schuster, Theory of Optics (1904); P. Drude, Theory of Optics, Eng. trans. by C. R. Mau and R. A. Millikan (1902). General treatises of exceptional merit are A. Winkelmann, Handbuch der Physik, vol. vi. Optik (1872); Max von Pettenkofer, Lehrbuch der Physik (1872); E. E. Leithé, Lesions d’optique physique (1869, 1872) is also a valuable work. Geometrical optics is treated in R. S. Heath, Geometrical Optics (2nd ed., 1889); H. A. Herma, Treatise on Geometrical Optics (1892); R. G. Jones, Theoretical and Practical Optics (1899); and optical instruments, is treated in H. D. Taylor, A System of Applied Optics (1906); E. T. Whittaker, The Theory of Optical Instruments (1907); in the publications of the scientific staff of the Zeiss works at Jena: The Theorie der optischen Instrumente, vol. i. “Die Bilderrzeugung in optischen Instrumenten” (1904); in S. Czapski, Theorie der optischen Instrumente, 2nd ed. by O. Eppenstein (1904); and in A. Steinheil and E. Voit, Handbuch der angewandten Optik (1901). The mathematical theory of general optics receives historical and modern treatment in the Encyclopädie der mathematischen Wissenschaften (Leipzig). Meteorological optics is fully treated in J. Ferrier, Meteorologische Optik (1872); a French translation in H. v. Helmholtz, Handbuch der physiologischen Optik (1896) and in A. Koenig, Sammelbände Abhandlungen zur physiologischen Optik (1903).

The history of the subject may be studied in J. C. Foggendorff, Geschichte der Physik (1882-1890); G. F. Struve, Geschichte der Physik (1882-1890); E. Gerland and F. Traunmüller, Geschichte der physikalischen Experimentierkunst (1899); reference may also be made to Joseph Priestley, History and Present State of Discoveries in Light and Colours (1767, 1772), German translation by G. S. Klügel (Leipzig, 1775). Original memoirs are available in many cases in their author’s “collected works,” e.g. Huygens, Young, Fresnel, Hamilton, Cauchy, Rowland, Clerk Maxwell, Stokes. Several of his papers on Optics are collected in E. Chasles, Die Getreuheit der Optik (1871-1875), German translation by G. S. Klügel (Leipzig, 1775). Original memoirs are available in many cases in their author’s “collected works,” e.g. Huygens, Young, Fresnel, Hamilton, Cauchy, Rowland, Clerk Maxwell, Stokes. Several of his papers on Optics are collected in E. Chasles, Die Getreuheit der Optik (1871-1875), German translation by G. S. Klügel (Leipzig, 1775).
a marked change is observed when a second piece of glass is made to approach the reflecting face, so as to be separated from it only by a very thin layer of air. The reflection is then found no longer to be total, part of the light finding its way into the second piece of glass. Newton concluded from this that the corpuscles are attracted by the glass even at a certain measurable distance.

3. **New Hypotheses in the Corpuscular Theory.**—The preceding explanation of reflection and refraction is open to a very serious objection. If the particles in a beam of light all moved with the same velocity and were acted on by the same forces, they all ought to follow exactly the same path. In order to understand that part of the incident light is reflected and part of it transmitted, Newton imagined that each corpuscle undergoes certain alternating changes; he assumed that in some of its different “phases” it is more apt to be reflected, and in others more apt to be transmitted. The same idea was applied by him to the phenomena presented by very thin layers. He had observed that a gradual increase of the thickness of a layer produces periodic changes in the intensity of the reflected light, and he very ingeniously explained these by his theory. It is clear that the intensity of the transmitted light will be a minimum if the corpuscles that have traversed the front surface of the layer, having reached that surface while in their phase of easy transmission, have passed to the opposite phase the moment they arrive there. At the nature of the alternating phases, Newton (Opticks, 3rd ed., p. 347) assigns himself, as follows:—**“Nothing more is requisite for putting the Rays of Light into Fits of easy Reflexion and easy Transmission than that they be small Bodies which by their attractive Powers, or some other Force, stir up Vibrations in what they act upon, which Vibrations being swifter than the Rays, overtake them successively, and agitate them so as by turns to increase and decrease their Velocities, and thereby put them into those Fits.”**

4. **The Corpuscular Theory and the Wave-Theor[y compared.**—Though Newton introduced the notion of periodic changes, which was to play so prominent a part in the later development of the wave-theory, he rejected this theory in the form in which it had been set forth shortly before by Christian Huygens in his Traité de la lumière (1690), his chief objections being: (1) that the rectilinear propagation had not been satisfactorily accounted for; (2) that the motions of heavenly bodies show no sign of a resistance due to a medium filling all space; and (3) that Huygens had not sufficiently explained the peculiar properties of the rays produced by the double refraction in Iceland spar. In Newton’s days these objections were of much weight.

Yet his own theory had many weaknesses. It explained the propagation in straight lines, but it could assign no cause for the equality of the speed of propagation of all rays. It adapted itself to a large variety of phenomena, even to that of double refraction (Newton says ibid.: “... the unusual Refraction of Iceland Crystal looks very much as if it were performed by some kind of attractive virtue lodged in certain Sides both of the Rays, and of the Particles of the Crystal.”), but it could do so only at the price of losing much of its original simplicity.

In the earlier part of the 19th century, the corpuscular theory broke down under the weight of experimental evidence, and it received the final blow when J. B. L. Foucault proved by direct experiment that the velocity of light in water is not greater than that in air, as it should be according to the formula (1), but less than it, as is required by the wave-theory.

5. **General Theorems on Rays of Light.**—With the aid of suitable assumptions the Newtonian theory can accurately trace the course of a ray of light in any system of isotropic bodies, whether homogeneous or otherwise; the problem being equivalent to that of determining the motion of a material particle in a space in which its potential energy is given as a function of the coordinates. The application of the dynamical principles of “least and of varying action” to this latter problem leads to the following important theorems which William Rowan Hamilton made the basis of his exhaustive treatment of systems of rays.1 The total energy of a corpuscle is supposed to have a given value, so that, since the potential energy is considered as known at every point, the velocity $v$ is so likewise.

(a) The path along which light travels from a point $A$ to a point $B$ is defined by the condition that for this line the integral $\int f ds$, in which $ds$ is an element of the line, be a maximum (provided $A$ and $B$ be not too near each other). Therefore, since $v = \mu v$, if $v$ is the velocity of light in vacuo and $\mu$ the index of refraction, we have for every variation of the path the points $A$ and $B$ remaining fixed,

$$\delta s f ds = m q v \cos \theta,$$

where $\mu$ is the value of $\mu$ at the point $B$.

6. **General Considerations on the Propagation of Waves.**—“Waves,” i.e. local disturbances of equilibrium travelling onward with a certain speed, can exist in a large variety of systems. In a theory of these phenomena, the state of things at a definite point may in general be defined by a certain directed or vector quantity $\mathbf{P}$, which is zero in the state of equilibrium, and may be called the disturbance (for example, the velocity of the air in the case of sound vibrations, or the displacement of the particles of a fluid from their positions of equilibrium). The components $P_x, P_y, P_z$ of this disturbance in the directions of the axes of coordinates are to be considered as functions of the coordinates $x, y, z$ and the time $t$, determined by a set of partial differential equations, whose form depends on the nature of the problem considered. If the equations are homogeneous and linear, as they always are for sufficiently small disturbances, the following theorems hold.

(a) Values of $P_x, P_y, P_z$ (expressed in terms of $x, y, z, t$) which satisfy the equations will do so still after multiplication by a common arbitrary constant.

(b) Two or more solutions of the equations may be combined into a new solution by addition of the values of $P_x$ of $P_y, \ldots$ &c. in each vector $\mathbf{P}$ by compounding the vectors $\mathbf{P}$, such as are each of the particular solutions.

In the application to light, the first proposition means that the propagation of reflection, refraction, &c., can be produced in the same way with strong as with weak light. The second proposition contains the principle of the “superposition” of different states, on which the explanation of all phenomena of interference is made to depend.

In the simplest cases (monochromatic or homogeneous light) the disturbance is a simple harmonic function of the time ($\mathbf{P}$ simple harmonic vibrations”), so that its components can be represented by

$$P_x = A \cos (mt + f_x), P_y = A \cos (mt + f_y), P_z = A \cos (mt + f_z).$$

The “phases” of these vibrations are determined by the angles $nt + f_x$, &c., or by the times $t + n/\omega$, &c. The “frequency $\omega$ is constant throughout the system, while the quantities $f_x, f_y, f_z$, and perhaps the “amplitudes” $A_x, A_y, A_z$ change from point to point. It may be shown that the end of a straight line representing the vector $\mathbf{P}$, and drawn from the point considered, in general describes a certain ellipse, which becomes a straight line, if $f_x = f_y = f_z$. In this latter case, to which the larger part of this article will be confined, we can write in vector notation

$$\mathbf{P} = A \cos (mt + f),$$

where $A$ itself is to be regarded as a vector.

We have next to consider the way in which the disturbance changes from point to point. The most important case is that of plane waves with constant amplitude $A$. Here $f$ is the same at all points of a plane (“wave-front”) of a definite direction, but changes as a linear function as we pass from one such wave-front to the next. The axis of $x$ being drawn at right angles to the wave-fronts, we may write $f = f_0 - kx$, where $f_0$ and $k$ are constants, so that (4) becomes

$$\mathbf{P} = A \cos (nt - kx + f).$$

This expression has the period $2\pi n$ with respect to the time and the period $2\pi k$ with respect to $x$, so that the “time of vibration” and the “wave-length” are given by $T = 2\pi n, \lambda = 2\pi k$. Further, it is easily shown that the phase belonging to certain values of $x$ and $t$ is equal to that which corresponds to $x + \Delta x$ and $t + \Delta t$ provided $\Delta x = (n/\lambda)\Delta t$. Therefore the phase, or the disturbance itself, may be said to be propagated in the direction normal to the wave-fronts with a velocity (velocity of the waves) $v = n/\lambda$, which is connected with the time of vibration and the wave-length by the relation

$$\lambda = v T.$$
In isotropic bodies the propagation can go on in all directions with the same velocity. In anisotropic bodies (crystals), with which the theory of light is largely concerned, the problem is more complicated. As a general rule we can say that, for a given direction of the wave-front, the wave-motion can propagate in all directions whatever the velocity of propagation, and to a portion of the new wave-front whose boundary passes through the points where the surface touches the elementary waves having their centres on \( s \). Taking for granted Huygens' assumption that a second disturbance is set up only for the points on the wave-front whose waves are touched by the new wave-front, it may be inferred that the lateral limits of the beam of light are determined by lines, each element of which joins the centre \( P \) of an elementary wave with its image after two reflections. This construction shows that, corresponding to each direction of the wave-front (with a determinate direction of vibration), there is a definite direction and a definite velocity of the ray. Both are given by a line drawn from the centre of the wave-surface to its point of contact with a tangent plane of the given direction. It will be convenient to say that this line and the plane are conjugate with each other. The rays of light, curved in non-homogeneous bodies, are always such as to be refracted and not be reflected (with the exception of those rays which are normal to the wave-fronts, and their velocity is equal to that of the waves).

By applying his construction to the reflection and refraction of light, Huygens accounted for these phenomena in isotropic bodies (see p. 619). The theory of the formation of the wave-fronts was afterwards shown by Augustin Fresnel that the double refraction in biaxial crystals can be explained in the same way, provided the proper form be assigned to the wave-surface. In an optical medium, whether homogeneous or otherwise, if they are normal to the wave-fronts, and their velocity is equal to that of the waves.

In any point of a bounding surface the normals to the reflected and refracted waves, whatever be their number, always lie in the plane passing through the normal to the incident waves and that to the surface itself. Moreover, if \( n_1 \) is the angle between these two normals, and \( n_2 \) the normal to the boundary and that to any one of the reflected and refracted waves, and \( n_1, n_2 \) the corresponding wave-velocities, the relation

\[
\sin n_1/\sin n_2 = v_1/v_2, \tag{7}
\]

is found to hold in all cases. These important theorems may be proved independently of Huygens' construction by simply observing that, at each point of the surface of separation, there must be a certain connexion between the normals to the incident, the reflected, and the refracted waves, and that, therefore, the lines of intersection of the surface with the positions of an incident wave-front, succeeding each other at equal intervals of time \( dt \), must correspond to the lines on which the surface is intersected by a similar series of reflected or refracted wave-fronts. In the case of isotropic media, the ratio \( \mu \) is constant, so that we are led to the law of Snellius, the index of refraction being given by

\[
\mu = n_1/n_2, \tag{8}
\]

(cf. equation 1).

(a) Let A and B be two points arbitrarily chosen in a system of transparent bodies, \( d \) an element of a line drawn from A to B, \( u \) the velocity of a ray of light coinciding with \( d \). Then the integral \( \int u \, ds \) represents the time required for a motion along the line with the velocity \( u \), is a minimum for the course actually taken by a ray of light (unless A and B be too far apart). This is the principle of least time" first formulated by Pierre de Fermat for the case of two isotropic substances. It shows that the course of a ray of light can always be inverted.

(b) Rays of light starting in all directions from a point A and traveling onward for a definite length of time, reach a surface \( s \), whose tangent plane at a point B is conjugate, in the medium surrounding \( s \), with the last element of the ray AB.

(c) If all rays issuing from A are concentrated at a point B, the integral \( \int v \, ds \) has the same value for each of them.

(d) In case \( \theta \) the variation of the integral caused by an infinitely small disturbance in the element of the wave-front is determined by

\[
\delta \int u \, ds = q \cos \theta / \theta . \tag{9}
\]

Here \( q \) is the angle between the displacement \( q \) and the normal to the surface \( s \), in the direction of propagation, of the velocity of a plane wave tangent to this surface.

In the case of isotropic media, the integral \( \int u \, ds \) over the course of a ray is determined by the integral \( \int \frac{\partial^2}{\partial n^2} q \, ds \) over the surface which we have deduced from the emission theory (§ 5).

10. Further General Theorems.—(a) Let \( V_1 \) and \( V_2 \) be two planes in a system of isotropic bodies, let rectangular axes of coordinates be chosen in each of these planes, and let \( x_1 \) and \( y_1 \) be the coordinates of a point A in \( V_1 \), and \( x_2, y_2 \) those of a point B in \( V_2 \). The integral \( \int u \, ds \), taken for the ray between A and B, is a function of \( x_1, y_1, x_2, y_2 \) and, if \( s \) denotes either \( x_1 \) or \( y_1 \), and \( s' \) either \( x_2 \) or \( y_2 \), we shall have

\[
\int_{x_1}^{x_2} \frac{\partial^2}{\partial n^2} q \, ds = \int_{y_1}^{y_2} \frac{\partial^2}{\partial n^2} q \, ds. \tag{10}
\]

On both sides of this equation the first differentiation may be performed by means of the formula (3). The second differentiation admits of a geometrical interpretation, and the formula may finally be employed for proving the following theorem:

Let \( \omega_1 \) be the solid angle of an infinitely thin pencil of rays issuing from a point A, and \( \omega_2 \) the solid angle of the new pencil of rays issuing from an element \( e \) at the point B. Similarly, let \( \omega_3 \) be the solid angle of a pencil starting from B and falling on the element \( e \) of the plane \( V_1 \) at the point A. Then, denoting by \( u_1, u_2, u_3 \) the indices of refraction of the matter through which the rays pass, we have

\[
\frac{\partial^2}{\partial n^2} q = u_1 u_2 / u_3. \tag{11}
\]

There is a second theorem that is expressed by exactly the same formula, if we understand by \( s_1 \) and \( s_2 \) elements of surface that are related to each other as an object and its optical image—by \( \omega_1, \omega_2, \omega_3 \) the infinitely small openings, at the beginning and the end of its course of a pencil of rays issuing from a point A of \( s_1 \) and coming together at the corresponding point B of \( s_2 \) and \( \theta_1, \theta_2 \) the sharp angles which one of the rays makes with the normals to \( s_1 \) and \( s_2 \). The proof may be based upon the first theorem. It suffices to
consider the section \( \sigma \) of the pencil by some intermediate plane, and a bundle of rays starting from the points of \( \sigma_1 \) and reaching those of \( \sigma_2 \) after having all passed through a point of that section \( \sigma \). 

(c) If in the last theorem the system of bodies is symmetrical around a straight line \( AB \), we can take for \( \sigma_1 \) and \( \sigma_2 \) circular planes having \( AB \) as axis as well. Let \( h_1 \) and \( k_1 \) be the radius of these circles, i.e., the linear dimensions of an object and its image, \( \epsilon_1 \) and \( \epsilon_2 \) the infinitely small angles which a ray \( R \) going from \( A \) to \( B \) makes with the axis at these points. Then the above formula gives

\[ \frac{\mu_1 k_1}{2 \epsilon_1} = \frac{\mu_2 k_2}{2 \epsilon_2}, \]

a relation which was proved, for the particular case \( \mu_1 = \mu_2 \) by Huygens and Lagrange. 

It is still more valuable if one distinguishes by the algebraic sign of \( h_1 \) whether the image is direct or inverted, and by that of \( \epsilon_2 \) whether the ray \( R \) on leaving \( A \) and on reaching \( B \) lies on the opposite side or on the same side.

The above theorems are of much service in the theory of optical instruments and in the general theory of radiation.

11. Phenomena of Interference and Diffraction.—The impulses or motions which a luminous body sends forth through the universal medium or aether, were considered by Huygens as being without any regular succession; he neither speaks of vibrations, nor of the physical cause of the colours. The idea that monochromatic light consists of a succession of simple harmonic vibrations like those represented by the equation (5), and that the sensation of colour depends on the frequency, is due to Thomas Young¹ and Fresnel,² who explained the phenomena of interference on this assumption combined with the principle of super-position. In doing so they were also enabled to determine the wave-length, ranging from \( 0.0000076 \) cm. at the red end of the spectrum to \( 0.0000039 \) cm. for the extreme violet and, by means of the formula (6), the number of vibrations per second. Later investigations have shown that the infra-red rays as well as the ultra-violet ones are of the same physical nature as the luminous rays, differing from these only by the greater or smaller length of their waves. The wave-length amounts to \( 0.006 \) cm. for the weakest infra-red, and is as small as \( 0.00001 \) cm. for the extreme ultra-violet.

Another important part of Fresnel’s work is his treatment of diffraction on the basis of Huygens’s principle. If, for example, light falls on a screen with a narrow slit, each point of the slit is regarded as a new centre of vibration, and the intensity at any point behind the screen is found by combining with each other the disturbances coming from all these points, due account being taken of the phases with which they come together (see Diffraction; Interference).

12. Results of Later Mathematical Theory.—Though the theory of diffraction developed by Fresnel, and by other physicists who worked on the same lines, shows a most beautiful agreement with observed facts, yet its foundation, Huygens’s principle, cannot, in its original elementary form, be deemed quite satisfactory. The general validity of the results has, however, been confirmed by the researches of those mathematicians (Siméon Denis Poisson, Augustin Louis Cauchy, Sir G. G. Stokes, Gustav Robert Kirchhoff) who investigated the propagation of vibrations in a more rigorous manner. Kirchhoff³ showed that the disturbance at any point of the aether inside a closed surface which contains no ponderable matter can be represented as made up of a large number of parts, each of which depends upon the state of things at one point of the surface. This result, the modern form of Huygens’s principle, can be extended to a system of bodies of any kind, the only restriction being that the source of light be not surrounded by the surface.

Certain causes capable of producing vibrations can be imagined to be distributed all over this latter, in such a way that the disturbances to which they give rise in the enclosed space are exactly those which are brought about by the real source of light.⁴ Another interesting result that has been verified by experiment is that, whenever rays of light pass through a focus, the phase undergoes a change of half a period.

This must be added that the results alluded to in the above, though generally presented in the terms of some particular form of the wave theory, often apply to other forms as well.

13. Rays of Light.—In working out the theory of diffraction it is possible to state exactly in what sense light may be said to travel in straight lines. Behind an opening whose width is very large in comparison with the wave-length the limits between the illuminated and the dark spaces of air are approximately determined that by rays passing along the borders.

This conclusion can also be arrived at by a mode of reasoning that is independent of the theory of diffraction.⁶ If linear differential equations admit a solution of the form (5) with \( A \) constant, they can also be satisfied by making \( A \) a function of the coordinates, such that it may always be expressed exactly equal to \( A \), the wave-length, and that it is constant along each line conjugate with the wave-fronts. In cases of this kind the disturbance may truly be said to travel along lines of the said direction, and an observer who is unable to discern lengths of the order of \( \lambda \) and who uses an opening of much larger dimensions, may very well have the impression of a cylindrical beam with a sharp boundary.

A similar result is found for curved waves. If the additional restriction is made that their radii of curvature be very much larger than the wave-length, Huygen’s construction may confidently be employed. The amplitudes all along a ray are determined by, and proportional to, the amplitude at one of its points.

14. Polarized Light.—As the theorems used in the explanation of interference and diffraction are true for all kinds of vibratory motions, these phenomena can give us no clue to the special kind of vibrations in light-waves. Further information, however, may be drawn from experiments on plane polarized light. The properties of a beam of this kind are completely known when the position of a certain plane passing through the direction of the rays, and in which the beam is said to be polarized, is given. “This plane of polarization,” as it is called, coincides with the plane of incidence in those cases where the light has been polarized by reflection on a glass surface under an angle of incidence whose tangent is equal to the index of refraction (Brewster’s law).

The researches of Fresnel and Arago left no doubt as to the direction of the vibrations in polarized light with respect to that of the rays themselves. In isotropic bodies at least, the vibrations are exactly transverse, i.e., perpendicular to the rays, either in the plane of polarization or at right angles to it. The first part of this statement also applies to unpolarized light, as this can always be dissolved into polarized components.

Much experimental work has been done on the production of polarized rays by double refraction and on the reflection of polarized light, either by isotropic or by anisotropic transparent bodies, the object of inquiry being in the latter case to determine the position of the plane of polarization of the reflected rays and their intensity.

In this way a large amount of evidence has been gathered by which it has been possible to test different theories concerning the nature of light and that of the medium through which it is propagated. A common feature of nearly all these theories is that the ether is supposed to exist not only in spaces void of matter, but also in the interior of ponderable bodies.

15. Fresnel’s Theory.—Fresnel and his immediate successors assimilated the aether to an elastic solid, so that the velocity of propagation of transverse vibrations could be determined by the formula

\[ w = \sqrt{\frac{K}{\rho}}, \]

where \( K \) denotes the modulus of rigidity and \( \rho \) the density. According to this equation the different properties of various isotropic transparent bodies may arise from different values of \( K \), of \( \rho \), or of both. It has, however, been found that if both \( K \) and \( \rho \) are supposed to change from one substance to another, it is impossible to obtain the right reflection formula. Assuming the theory of Fresnel, that the wave-crests are always parallel to the observed properties of the reflected light, if he made the further assumption (to be mentioned in what follows as “Fresnel’s assumption”) that the vibrations of plane polarized light are perpendicular to the plane of polarization.

It follows from these principles that, in an isotropic dielectric, transverse electric vibrations can be propagated with a velocity
\[ v = c / \sqrt{\varepsilon}. \]

Indeed, all conditions are satisfied if we put
\[ D_z = 0, \quad D_y = a \cos (n(x^{-1} - y^{-1} + l)), \quad D_x = 0, \quad H_z = 0, \quad H_y = a \varepsilon c^2 \cos (n(x^{-1} - y^{-1} + l)) \]

For the free aether the velocity has the value \( c \). Now it has been concluded that the ratio \( c \) between the two degrees of freedom within the limits of experimental errors with the numerical value of the velocity of light in aether. (The mean result of the most exact determinations of \( c \) is \( 3.001 \times 10^8 \text{ cm/s} \), the largest deviations being about \( 0.008 \times 10^8 \text{ cm/s} \) and \( 0.003 \times 10^8 \text{ cm/s} \) as the most probable value of the velocity of light.) By this Maxwell was led to suppose that light consists of transverse electromagnetic disturbances. On this assumption, the equations (16) represent a local representation of the plane polarized light that, in such a beam, there are at the same time electromagnetic vibrations, both transverse, and at right angles to each other.

It must be added that the electromagnetic field is the seat of two kinds of energy distinguished by the names of electric and magnetic energy, and that, according to a beautiful theorem due to J. H. Poynting, the energy may be conceived to flow in a direction perpendicular to both the electric and to the magnetic force. The amounts per unit of volume of the electric and magnetic energy are given by the expressions
\[ \frac{1}{2} \varepsilon E_x^2, \quad \frac{1}{2} \mu D_y^2 - \frac{1}{2} \mu D_x^2, \]
and
\[ \frac{1}{2} \mu B_y^2 + \varepsilon E_x B_y = \varepsilon H_y^2. \]

whose mean values for a full period are equal in every beam of light.

James Clerk Maxwell, who had set himself the task of mathematically working out Michael Faraday's views, and who, both by doing and by introducing many new ideas of his own, became the founder of the modern science of electricity, recognized that, at every point of an electromagnetic field, the state of things can be defined by two vector quantities, the "electric force" \( E \) and the "magnetic force" \( B \), which are the state of things at a given point of the electric and magnetic field. The latter that which acts on a magnetic pole of unit strength. In a non-conductor (dielectric) the force \( E \) produces a state that may be described as a displacement of electricity from its position of equilibrium. This state is represented by a vector \( D \) ("dielectric displacement "). Whose magnitude is measured by the quantity of electricity reckoned per unit area which has traversed an element of surface perpendicular to \( D \) itself. Similarly, there is a vector quantity \( B \) (the "magnetic induction ") intimately connected with the magnetic force \( H \). Changes of the dielectric displacement constitute an electric current measured by the rate of change of \( D \), and represented in vector notation by
\[ C \equiv D \]

Periodic changes of \( D \) and \( B \) may be called "electric" and "magnetic vibrations". Properly choosing the units, the axes of coordinates (in the first proposition also the positive direction of \( s \) and \( n \)), and denoting components of vectors by suitable indices, we can express in the following way the fundamental propositions of the theory.

(a) Let \( C \) be a homogeneous, \( \sigma \) a surface bounded by it, \( n \) the normal to \( \sigma \). Then, for all bodies,
\[ \int \mathbf{H} d\mathbf{s} = \int \mathbf{C} d\sigma, \quad \int \mathbf{E} d\mathbf{s} = - \int \frac{d}{dt} d\mathbf{B} d\sigma, \]
where the constant \( c \) means the ratio between the electro-magnetic and the electrostatic unit of electricity.

From these equations we can deduce:

\[ \frac{\partial H_x}{\partial t} - \frac{\partial D_y}{\partial x} = \frac{1}{c^2} \frac{\partial E_y}{\partial t} - \frac{\partial E_x}{\partial x}, \quad \frac{\partial H_y}{\partial t} - \frac{\partial D_x}{\partial y} = \frac{1}{c^2} \frac{\partial E_x}{\partial t} - \frac{\partial E_y}{\partial y} \]

(b) For a surface of separation, the continuity of the tangential components of \( E \) and \( H \).

(c) The solenoidal distribution of \( C \) and \( B \), and in a dielectric that of \( D \). A solenoidal distribution of a vector is one corresponding to that of the velocity in an incompressible fluid. It involves the continuity, at a surface, of the normal component of the vector.

(d) The relation between the electric force and the dielectric displacement is expressed by
\[ \mathbf{D} = \varepsilon \mathbf{E}, \quad \mathbf{D}_z = \varepsilon \mathbf{E}_z, \quad \mathbf{D}_x = \varepsilon \mathbf{E}_x, \quad \mathbf{D}_y = \varepsilon \mathbf{E}_y, \]
the constants \( \varepsilon, \mu \) (dielectric constants) depending on the properties of the body. An isotropic medium has a common value \( \varepsilon \), which is equal to unity for the free aether, so that for this medium \( \mathbf{D} = \mathbf{E} \).

There is a relation similar to (14) between the magnetic force and magnetic induction. For the aether, however, and for all ponderable bodies with which this article is concerned, we may write \( \mathbf{B} = \mathbf{H} \).

to contain, besides the numbers given in § 11, the lengths of the waves produced by electromagnetic apparatus and extending from the long waves used in wireless telegraphy down to about 0.6 cm.

17. Mechanical Models of the Electromagnetic Medium.—From the results already enumerated, a clear idea can be formed of the difficulties which were encountered in the older form of the wave-theory. Whereas, in Maxwell’s theory, longitudinal vibrations are excluded ab initio by the solenoidal distribution of the electric current, the elastic-solid theory had to take them into account, unless, as was often done, one made them disappear by supposing them to have a very great velocity of propagation, so that the ether was considered to be practically incompressible. Even on this assumption, however, much in Fresnel’s theory remained questionable. Thus George Green, who was the first to so assign the theory an unobjectionable manner, arrived on Fresnel’s assumption at a formula for the reflection coefficient $A$, sensibly differing from (16).

In the theory of double refraction the difficulties are no less serious. As a general rule there are in an anisotropic elastic solid three possible directions of vibration (§ 6), at right angles to each other, for a given direction of the waves, but none of these lies in the wave-front. In order to make two of them so do and to find Fresnel’s form for the wave-surface, new hypotheses are required. On Fresnel’s assumption it is even necessary, as was observed by Green, to suppose that in the absence of all vibrations there is already a certain state of pressure in the medium.

If we adhere to Fresnel’s assumption, it is indeed scarcely possible to construct an elastic model of the electromagnetic medium. It may be done, however, if the velocities of the particles in the model are taken to represent the magnetic force $H$, which, of course, implies that the vibrations of the particles are parallel to the plane of polarization, and that the magnetic energy is represented by the kinetic energy in the model. Considering further that, in the case of two bodies connected with each other, there is continuity of $H$ in the electromagnetic system, and continuity of the velocity of the particles in the model, it becomes clear that the representation of $H$ by elastic waves must be on the same scale in all substances, so that, if $\xi$, $\eta$, $\zeta$ are the displacements of a particle and $g$ a universal constant, we may write

$$H = \frac{\partial \xi}{\partial t}, \quad H = \frac{\partial \eta}{\partial t}, \quad H = \frac{\partial \zeta}{\partial t}. \tag{19}$$

By this the magnetic energy per unit of volume becomes

$$\frac{1}{2g^2} \left[ \left( \frac{\partial \xi}{\partial t} \right)^2 + \left( \frac{\partial \eta}{\partial t} \right)^2 + \left( \frac{\partial \zeta}{\partial t} \right)^2 \right]$$

and since this must be the kinetic energy of the elastic medium, the density of the latter would have to be taken equal to $g^2$, so that it must be the same in all substances.

It may further be asked what value we have to assign to the potential energy in the model, which must correspond to the electric energy in the electromagnetic field. Now, on account of (11) and (19), we can satisfy the equations (12) by putting $D = \frac{g^2}{2 \xi g^2 g^2 g^2}$

and this, therefore, must be the energy in the model.

It may be shown, indeed, that, if the ether has a uniform constant density, and is so constituted that in any system, whether homogeneous or not, its potential energy per unit of volume can be represented by an expression of the form

$$\frac{1}{2} \left[ L \left( \frac{\partial \xi}{\partial t} \right)^2 + \frac{M}{2} \left( \frac{\partial \eta}{\partial t} \right)^2 + N \left( \frac{\partial \zeta}{\partial t} \right)^2 \right], \tag{20}$$

where $L$, $M$, $N$ are coefficients depending on the physical properties of the substance considered, this representation will exactly correspond to the equations of the electromagnetic field.

18. Theories of Neumann, Green, and MacCullagh.—A theory of light in which the elastic aether has a uniform density, and in which the vibrations are supposed to be parallel to the plane of polarization, was developed by Franz Ernst Neumann, who gave the first deduction of the formulas for crystalline reflection. Like Fresnel, he was, however, obliged to introduce some illegitimate assumptions and simplifications. Here again Green indicated a more rigorous treatment.

By specializing the formula for the potential energy of an anisotropic body he arrives at an expression which, if some of his coefficients are made to vanish and if the medium is supposed to be incompressible, differs from (20) only by the additional terms

$$- \frac{g^2}{2} \left( \frac{\partial \xi}{\partial t} \right)^2, \quad - \frac{g^2}{2} \left( \frac{\partial \zeta}{\partial t} \right)^2. \tag{21}$$

If $\xi$, $\eta$, $\zeta$ vanish at infinite distance the integral of this expression over all space is zero, when $L$, $M$, $N$ are constants, and the same will be true when these coefficients change from point to point, provided we add to (21) certain terms containing the differential coefficients of $L$, $M$, $N$, the physical meaning of these being

that, besides the ordinary elastic forces, there is some extraneous force (called into play by the displacement) acting on all those elements of volume where $L$, $M$, $N$ are not constant. We may conclude from this that all phenomena can be explained if we admit the existence of this latter, which, in the case of certain two-continuous bodies, reduces to a surface-action on their common boundary.

James MacCullagh avoided this complication by simply assuming an expression of the form (20) for the potential energy. He thus established a theory which, in its general form, is unobjectionable as regards the form of the equations for transparent bodies. Lord Kelvin afterwards interpreted MacCullagh’s assumption by supposing the only action which is possible, by a discussion of the contrary to consist in certain couples acting on the elements of volume and proportional to the components $\{\partial^2g^2\partial^2g^2\partial^2g^2\partial^2g^2\}$, &c., of their rotation from the natural position. He also showed that this “rotational elasticity” can be produced by certain hidden rotations going on in the medium.

We cannot dwell here upon other models that have been proposed, and most of which are of rather limited applicability. A mechanism of a more general kind ought, on the contrary, to be adapted to what is known of the molecular constitution of bodies, and to the highly probable assumption of the perfect permeability for the aether of all ponderable matter, an assumption by which it has been possible to escape from one of the objections raised by Newton (§ 4) (see Aether). The possibility of a truly satisfactory model certainly cannot be denied. But it would, in all probability, be extremely complicated. For this reason many physicists rest content, as regards the free aether, with some such general form of the electromagnetic theory as has been sketched in § 16.

19. Optical Properties of Ponderable Bodies. Theory of Electromagnetic Waves.—If we want to form an adequate representation of optical phenomena upon the basis of their arrangement, and the molecular and atomic theories naturally suggest themselves. Already, in the elastic theory, it had been imagined that certain material particles are set vibrating by incandescent waves of light. These particles had been supposed to be acted on by an elastic force by which they are drawn back towards their positions of equilibrium, so that they can perform free vibrations of their own, and by a resistance that can be represented by terms proportional to the velocity in the equations of motion, and may be physically understood if the vibrations are supposed to be converted in one way or another into a disorderly heat-motion. In this way it had been found possible to explain the phenomena of dispersion and (selective) absorption, and the connexion between them (anomalous dispersion). These ideas have also been embodied into the electromagnetic theory. In its more recent development the extremely small, electrically charged particles, to which the name of “electrons” has been given, and which are supposed to exist in the interior of all bodies, are considered as playing the connecting links between aether and matter, as determinative as do their own movement and their motion all optical phenomena that are not confined to the free aether.

It has thus become clear why the relations that had been established between optical and electrical properties have been found to hold only in some simple cases (§16). In fact it cannot be doubted that, for rapidly alternating electric fields, the formulæ expressing the connexion between the motion of electricity and the electric force take a form that is less simple than the one previously admitted, and is to be determined in each case by the directions of the waves and the properties of the medium.

---

elaborate investigation. However, the general boundary conditions given in §6 seem to require no alteration. For this reason it has been possible, for example, to establish a satisfactory theory of metallic reflection, that the propagation of light in the interior of a metal is only imperfectly understood.

One of the fundamental propositions of the theory of electrons is that an electron becomes a centre of radiation whenever its velocity changes either in direction or in magnitude. Thus the production of Röntgen rays, regarded as consisting of very short and irregular electromagnetic impulses, is traced to the impacts of the electrons on the cathode-rays against the anode, and the lines of an emission spectrum indicate the existence in the radiating body of as many kinds of regular vibrations, the knowledge of which is the ultimate object of our investigations about the structure of the spectra. The shifting of the lines caused, according to Doppler’s law, by a motion of the source of light, may easily be accounted for, as only general principles are involved in the explanation. To a certain extent we can also elucidate the changes in the emission that are observed when the radiating source is exposed to external magnetic forces (“Zeeman-effect”); see MAGNETO-Ortix)

20. Various Kinds of Light-motion.—(a) If the disturbance is represented by

\[ P = a e^{(n-t-kx)} + \frac{d}{dt} \cos (n-t-kx), \]

so that the end of the vector \( P \) describes an ellipse in a plane perpendicular to the direction of propagation, the light is said to be elliptically, or in special cases circularly, polarized. Light of this kind can be dissolved in many different ways into plane polarized components.

There are cases in which plane waves must be elliptically or circularly polarized in order to show the simple propagation of phase that is expressed by formulae (5). Instances of this kind may be found in bodies having the property of rotating the plane of polarization, either on account of their constitution, or under the influence of a magnetic field. For a given direction of the wave-front there are in general two kinds of elliptic vibrations, each having a definite form, orientation, and direction of motion, and a determinate velocity of propagation. All that has been said about Huygens’s construction applies to these cases.

(b) In a perfect spectrocope a sharp line would only be observed if an exact regular succession of simple harmonic vibrations were admitted into the instrument. In any other case the light will occupy a certain extent in the spectrum, and in order to determine its distribution we have to decompose into simple harmonic functions of the vibrations, at a point in question, for which we have been given as is the case with what is commonly called homogeneous light, no perfectly sharp line will be seen. There is no source of light in which the vibrations of the particles remain for ever undisturbed, and a particle will never emit an endless succession of uninterrupted vibrations, but at best a series of vibrations whose form, phase and intensity are changed at irregular intervals. The result must be a broadening of the spectral line.

In cases of this kind one must distinguish between the velocity of propagation of the phase of regular vibrations and the velocity with which the said changes travel onward (see below, iii. Velocity of Light).

(c) In a train of plane waves of definite frequency the disturbance is represented by the components of the vibrations of the time and the coordinates. Since the fundamental equations are linear, there are also solutions in which one or more of the coordinates occur in an exponential function. These solutions are of interest because the solutions corresponding to them are widely different from those of which we have thus far spoken. If, for example, the formulae contain the factor

\[ e^{-r \cos (nt-sy)} \]

with the positive constant \( r \), the disturbance is no longer periodic with respect to \( x \), but steadily diminishes as \( x \) increases. A state of things in which the energy is gradually die away as we leave the surface, exists in the air adjacent to the face of a glass prism by which a beam of light is totally reflected. It furnishes us an explanation of Newton’s experiment mentioned in §2.

(H. A. L.)

III. Velocity of Light

The fact that light is propagated with a definite speed was first brought out by Ole Roemer at Paris, in 1676, through observations of the eclipses of Jupiter’s satellites, made in different relative positions of the Earth and Jupiter in their respective orbits. It is possible in this way to determine the time required for light to pass across the orbit of the earth. The dimensions of this orbit, or the distance of the sun, being taken as known, the actual speed of light could be computed. Since this computation requires a knowledge of the sun’s distance, which has not yet been acquired with certainty, the actual speed is now determined by experiments made on the earth’s surface. Were it possible by any system of signals to compare with absolute precision the times at two different stations, the speed could be determined by finding how long was required for light to pass from one station to another at the greatest visible distance. But this is impracticable, because no natural agent is under our control by which a signal could be communicated with a greater velocity than that of light. It is therefore necessary to reflect a ray back to the point of observation and to determine the time which the light requires to go and come. Two systems have been devised for this purpose. One is that of Fizeau, in which the vital appliance is a rapidly revolving toothed wheel; the other is that of Foucault, in which the corresponding appliance is a revolving axis or, parallel to it, its own plane.

The principle underlying Fizeau’s method is shown in the accompanying fig. 1, and consists in the course of a ray of light which emanating from a luminous point described a circular arc on the plane surface of a glass M at an angle of about 45°. A fraction of the light is reflected from the two surfaces of the glass to a distant reflector R, the plane of which is at right angles to the plane of the glass M. The latter is thus reflected back on its own course and, passing through the glass M on its return, reaches a point E behind the glass. An observer with his eye at E would only see the glass, unless the ray returns from a distant luminous point in the reflector R, after the light has passed over the course in both directions. In actual practice it is necessary to interpose the object glass of a telescope at a point O, at a distance from M nearly equal to its focal length. The function of this appliance is to render the diverging rays, shown by the dotted lines, nearly parallel, in order that more light may reach R and be thrown back again. But the principle may be conceived without respect to the telescope, all the rays being ignored except the central one, which passes over the course we have described.

Conceiving the apparatus arranged in such a way that the observer sees the light reflected from the distant mirror R, a fine toothed wheel WX is placed immediately in front of the glass M, with its plane perpendicular to the course of the ray, in such a way that the ray goes out from and returns through an opening between two adjacent teeth. This wheel is represented in section by WX in fig. 1, and a part of its circumference, with the teeth as viewed by the observer, is shown in fig. 2. We conceive that the latter sees the luminous point between the two teeth, and that the ray is intercepted as every tooth passes through the course, so that what is sent out is a succession of flashes. Conceive that the speed of the mirror is such that while the flash is still visible the next tooth of the wheel takes the place of an opening between the teeth. Then each flash sent out will, on its return, be intercepted by the adjacent tooth, and will therefore be invisible. If the speed be now doubled, so that the tooth passes through the time required for the light to go and come, each flash sent through an opening will return through the adjacent opening, and will therefore be seen with full brightness. If the speed be continually increased the result will be successive disappearances and reappearances of the light, according as a tooth is or is not interposed when the ray reaches the apparatus on its return. The computation of the time of passage and return is then very simple. The speed of the wheel being known, the number of teeth passing in one second can be computed. The order of the disappearance, or the number of teeth which have passed while the light is going and coming, being also determined in each case, the interval of time is computed by a simple formula.
The most elaborate determination yet made by Fizeau's method was that of Cornu. The station of observation was at the Paris Observatory. The distant reflector, a telescope with a reflector at its focus, was at Montéhwy, distant 22,910 metres from the toothed wheel. Of this the reflector itself or dome has 150 teeth, and was 35 millimetres in diameter; the other had 200 teeth, with a diameter of 45 mm. The highest speed attained was about 600 revolutions per second. At this speed, 135,000 (or 180,000) teeth per second can be counted, while the light was going and coming. But the actual speed attained was generally less than this. The definitive result derived by Cornu from the entire series of experiments was 300,400 kilo- metres, or 98,327 miles, per second, which is, therefore, the speed of light.

The care with which Cornu placed his toothed wheel, and the improved system by which the speed of the wheel is continually varying, and it is impossible to determine with precision what it was at the instant of an eclipse.

The defect would be lessened were the speed of the toothed wheel placed under control of the observer, while the light was going and coming. But by choosing the moment when the light is of a certain definite brightness, before or after an eclipse, the observer will know at each instant whether the speed should be increased or retarded, and can act accordingly. The nearly constant speed through as long as this day may be expected to be divided by the number of revolutions of the wheel by the time through which the light was kept constant. But even with these improvements, which were not actually tried by Cornu, the time varies, and the accuracy would necessarily be uncertain. The outcome is that, although Cornu's discussion of his experiments is a model in the care taken to determine so far as practicable every source of error, his definition of this is a matter of opinion and observation.

An important improvement on the Fizeau method was made in 1886 by James Young and George Forbes at Glasgow. This consisted in using two distant reflectors which were placed nearly in the same straight line, but at unequal distances. The ratio of the distances was nearly 12:13. The phase observed was not that of complete extinction of either light, but that of the two lights appearing equal in intensity. But it does not appear that the very necessary device of placing the speed of the toothed wheel under control of the observer was adopted. The accordance between the different measures was far from satisfactory, and it will suffice to mention the result which was

\[ \text{Velocity in vacuo} = 301,382 \text{~km per sec.} \]

These experiments also found a difference of 2% between the speeds of red and blue light, a result which can only be attributed to some unexplained source of error.

The Foucault system is much more precise, because it rests upon the measurement of an angle, which can be made with great precision.

The vital appliance of a rapidly revolving mirror. Let AB (fig. 3) be a section of the reflector, which we first suppose at rest. A ray of light LM emanating from a source at L, is reflected in the direction MQR to a distant mirror R, from which it is perpendicularly reflected back upon its original course. This mirror R should be slightly concave, with the centre of curvature near M, so that the ray shall always be reflected back to M on whatever point of R it may fall. As the mirror M as at rest, the return ray will after three reflections, at M, R and M again, form an angle of 120° with the original ray. The returning ray comes to the point P from the reflected ray. If the motion is sufficiently rapid an eye observing the reflected ray will see the flashes as an invariable point of light so long as the speed of revolution remains constant. The time required for the light to go and come is then equal to that required by the mirror to turn through half the angle LMR, which is therefore measured. In practice it is necessary on this system, as in the case of the mirror of Cornu, to place the radius R and S so that the angles of the two mirrors, Q and R, shall be at conjugate focus. The position of the lenses may be either between the luminous point L and the mirror M, or between M and R, the latter being the only one shown in the figure. This position has the advantage that more light can be concentrated, but it has the disadvantage that, with a given magnifying power, the effect of atmospheric undulation, when the concave reflector is situated at a great distance, is increased in the ratio of the focal length, as the distance of the point from the mirror increases.

To state the fact in another form, the amplitude of the disturbances produced by the air in line measure are proportional to the focal length of the mirror, while the magnifications required increases in the ratio of the distance of the point from the mirror.

The Foucault system in the form in which its originator used it is that if the axis of the mirror is at right angles to the course of the ray, the light from the source L will be flashed directly into the eye to observe, on every occasion, that the direction of the ray through the position in which its normal bisect the two courses of the ray. This may be achieved by inclining the axis of the mirror.

In Foucault's determination the measures were not made upon a luminous point, but upon a reticule, the image of which could not be seen unless the reflector was quite near the revolving mirror. Indeed the whole apparatus was contained in his laboratory. The effective distance was increased by using several reflectors; but the correct position of the point of view was determined by comparing the results obtained with the Foucault system in the form in which its originator used it with the observations made with the Miehelson system, in which the light was kept constantly focused, while the direction of observation was changed. The essentials on the arrangement are those we have used in fig. 3, L being the slit. It would be seen that the revolving mirror is here interposed between the lens and its focus. It is revolved under the direct control of the observer, so that it could be kept at any required speed. The speed was determined by the vibrations of the tuning forks. One of these was an electric fork, making about 120 vibrations per second, with which the mirror was kept in unison by a small lamp. The other fork was kept at a definite phase by oscillating the fork. The speed of this fork was determined by comparison with a freely vibrating fork from time to time. The speed of the revolving mirror was generally about 275 turns per second, and the deflection of the image of the slit about 112.5 mm. The mean result of nearly 100 fairly accurate determinations was:

\[ \text{Velocity of light in air} = 299,828 \text{~km per sec.} \]

\[ \text{Reduction to a vacuum} +82 \]

\[ \text{Velocity of light in vacuo} = 299,910 \text{~km per sec.} \]

While this work was in progress Simon Newcomb obtained the official support necessary to make a determination on a yet larger scale. The most important modifications made in the Foucault-Miehelson system were the following:

1. Placing the reflector at the much greater distance of several kilometres.
2. In order that the disturbances of the return image due to the passage of the ray through more than 7 km. of air might be reduced to a minimum, an ordinary telescope of the "broken back" form was used to send the ray to the revolving mirror.
3. The speed of the mirror was, as in Michelson's experiments, completely under control of the observer, so that by drawing one or more revolutes of complete eclipse could be kept in any required position. In making each measure the receiving telescope hereafter described was placed in a fixed position and during the run "the image was kept as nearly as practicable at a fixed position by the action of a system of cross-wires which were adjusted at the beginning of each observation. The Essentials of the arrangement are those we have used in fig. 3, L being the slit. It would be seen that the revolving mirror is here interposed between the lens and its focus. It is revolved under the direct control of the observer, so that it could be kept at any required speed. The speed was determined by the vibrations of the tuning forks. One of these was an electric fork, making about 120 vibrations per second, with which the mirror was kept in unison by a small lamp. The other fork was kept at a definite phase by oscillating the fork. The speed of this fork was determined by comparison with a freely vibrating fork from time to time. The speed of the revolving mirror was generally about 275 turns per second, and the deflection of the image of the slit about 112.5 mm. The mean result of nearly 100 fairly accurate determinations was:

\[ \text{Velocity of light in air} = 299,828 \text{~km per sec.} \]

\[ \text{Reduction to a vacuum} +82 \]

\[ \text{Velocity of light in vacuo} = 299,910 \text{~km per sec.} \]
VELOCITY

LIGHT 625

of continuity, so that the angular measures were made between the directions of the return ray after reflection when the mirror moved in opposite directions. In this way the speed of the mirror was as good as doubled, and the possible constant errors inherent in the reference to dividing telescopes were eliminated. The essentials of the apparatus are shown in Fig. 4.

The revolving mirror was a rectangular prism M of steel, 3 in. high and 1½ in. on a side in cross section which was driven by a blast of air acting on two fan-wheels, not shown in the figure, one at the top, the other at the bottom of the mirror. NPO is the object-end of the fixed sending telescope the rays passing through it being reflected to the mirror by the receiver telescope. The receiving telescope ABO is straight, and has its objective under O. It was attached to a frame which could turn around the same axis as the mirror. The angle through which it moved was measured by a divided arc, and the base below its support, which is not shown in the figure. The position A'B is that for receiving the ray during a rotation of the mirror in the anti-clockwise direction; the position A'B that for a clockwise rotation.

In these measures the observation station was at Fort Myer, on a hill above town, on the west bank of the Potomac river. The distant reflector was first placed in the grounds of the Naval Observatory, at a distance of 2551 metres. But the definitive measures were made with the reflector at the base of the Washington monument, 3721 metres distant. The revolving mirror was not polished, but polished on all four vertical sides. Thus four reflections of the ray were received during each turn of the mirror, which would be coincident were the form of the mirror invariable. During the preliminary series of measures it was found that two images of the return ray were sometimes formed, which would result in two different conclusions as to the velocity of light, according as one or the other was observed. The only explanation of this difference was that in the revolving mirror, coinciding in period with that of revolution, but it was first thought that the effect was only occasional.

In the summer of 1881 the distant reflector was removed from the observatory to the monument station. Six measures made in August and September showed a systematic deviation of +67 km. per second from the result of the observatory series. This difference led to measures eliminating the defect from which it was supposed to arise. The pivots of the mirror were changed, which was a change made in the arrangement, which would permit of the effect of the vibration being determined and eliminated. This consisted in making the relative positive of the sending and receiving telescopes equal (AB). In this way, the difference in the measures of the return ray were sometimes formed, which would result in two different conclusions as to the velocity of light, according as one or the other was observed. The only explanation of this difference was that in the revolving mirror, coinciding in period with that of revolution, but it was first thought that the effect was only occasional.

In the summer of 1882, the results of which will first be stated in the form of the mean error of Newcomb's result, is shown to go and come. Expressed in millions of a second this was:

<table>
<thead>
<tr>
<th>Measure</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Least result</td>
<td>24,819</td>
</tr>
<tr>
<td>Greatest result</td>
<td>24,831</td>
</tr>
<tr>
<td>Double distance between mirrors</td>
<td>7,44242 km</td>
</tr>
</tbody>
</table>

Applying a correction of +12 km. for a slight convexity in the face of the revolving mirror, this gives as the mean result for the speed of light in air 299,778 km. per second. The mean results for the three series were:

<table>
<thead>
<tr>
<th>Measure</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Observatory, 1880-1881</td>
<td>V in air = 299,627</td>
</tr>
<tr>
<td>Monument, 1881</td>
<td>V = 299,094</td>
</tr>
<tr>
<td>Monument, 1882</td>
<td>V = 299,778</td>
</tr>
</tbody>
</table>

The last result being the only one from which the effect of distortion was completely eliminated, has been adopted as definitive. For reduction to a vacuum it requires a correction of +82 km. Thus the final result was concluded to be:

Velocity of light in vacuum 299,860 km. per second.

This result being less by 80 km. than that of Michelson, the latter made another determination with improved apparatus and arrangements at the Case School of Applied Science in Cleveland. The result was:

Velocity of light in vacuum 299,853 km. per second.

So far as could be determined from the discordance of the separate measures, the mean error of Newcomb's result would be less than ±10 km. But making allowance for the various sources of systematic error the actual probable error was estimated at ±30 km.

It seems remarkable that since these determinations were made, a period during which great improvements have become possible in every part of the apparatus, no complete restatement of this fundamental physical constant has been carried out.

The experimental measures thus far cited have been primarily by the velocity of light in air, the reduction to a vacuum being derived from theory alone. The fundamental constant at the basis of the whole theory is the speed of light in a vacuum, such as the celestial spaces. The question of the relation between the velocity in vacuo, and in a transparent medium of any sort, belongs to the domain of physical optics. Referring to the preceding section for the Principles at play we shall in the present part of the article confine ourselves to the experimental results. With the theory of the effect of a transparent medium is associated that of the possible differences in the speed of light of different colours.

The question whether the speed of light in vacuo varies with its wave-length seems to be settled with entire certainty by observations of variable stars. These are situated at different distances, some being so far that light must be several centuries in reaching us from them. Were there any difference in the speed of light of various colours it would be shown by a change in the colour of the star as its light waned and waxed. The light of greatest speed preceding that of lesser speed would, when emanated during the rising phase, impress its own colour on that which it overtook. The slower light would predominate during the falling phase. If there were a difference of 10 minutes in the time at which light from the two ends of the visible spectrum arrived, it would be shown by this test. As not the slightest effect of the kind has ever been seen, it seems certain that the difference, if any, cannot approximate to 1/10,000 part of the entire speed. The case is different when light passes through a refracting medium.

It is a theoretical result of the undulatory theory of light that its velocity in such a medium is inversely proportional to the refractive index of the medium. This being different for different colours, we must expect a corresponding difference in the velocity.

 Foucault and Michelson have tested these results of the undulatory theory by comparing the time required for a ray of light to pass through a tube filled with a refracting medium, and through air. Foucault thus found, in a general way, that there actually was a retardation; but his observations took account only of the mean retardation of light of all the wave-lengths, which he found to correspond with the undulatory theory. Michelson went further by determining the retardation of light of different wave-lengths in carbon bisulphide. He made two series of experiments, one with light near the brightest part of the spectrum; the other with red and blue light. Putting V for the speed in a vacuum and V, for that in the medium, his result was:

<table>
<thead>
<tr>
<th>Wave-Length</th>
<th>V : V,</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yellow light</td>
<td>1.758</td>
</tr>
<tr>
<td>Refractive index for yellow</td>
<td>1.64</td>
</tr>
<tr>
<td>Difference from theory</td>
<td>0.12</td>
</tr>
</tbody>
</table>

The estimated uncertainty was only 0.02, or 1/60 of the difference between observation and theory.

The comparison of red and blue light was made differentially. The colours selected were of wave-length about 0.62 for red and 0.49 for blue. Putting V, and V, for the speeds of red and blue light respectively in bisulphide of carbon, the mean result compared with theory as follows:

<table>
<thead>
<tr>
<th>Wave-Length</th>
<th>V, : V,</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wave-length</td>
<td>1.0245</td>
</tr>
<tr>
<td>Theoretical value (Verdet)</td>
<td>1.025</td>
</tr>
</tbody>
</table>

This agreement may be regarded as perfect. It shows that the difference of the speed of yellow light in the medium from theory, as found above, holds through the entire spectrum.

The excess of the retardation above that resulting from theory is probably due to a difference between "wave-speed" and "group-speed" pointed out by Rayleigh. Let fig. 5 represent a short series of progressive undulations of constant period and wave-length. The wave-speed is that required to carry a wave crest A to the position of the crest B in the wave time.
But when a flash of light like that measured passes through a refracting medium, the front waves of the flash are continually dying away, as shown at the end of the figure, and the place of each is taken by the wave following. A familiar case of this sort is seen when a stone is thrown into a pond. The front waves die out one at a time, to be followed by others, each of which goes further than its predecessor, while new waves are formed in the rear. Hence the group, as represented in the figure by the

\[ \text{Fig. 5.} \]

larger waves in the middle, moves as a whole more slowly than do the individual waves. When the speed of light is measured the result is not the wave-speed as above defined, but something less, because the result depends on the time of the group passing through the medium. This lower speed is called the group-velocity of light. In a vacuum there is no dying out of the waves, so that the group-speed and the wave-speed are identical.

From Michelson's experiments it would follow that the retardation was about \( \frac{1}{14} \) of the whole speed. This would indicate that in carbon bisulphide each individual light wave forming the front of a moving ray dies out in a space of about 15 wave-lengths.

**Authorities.—** For Foucault's descriptions of his experiments see *Comptes Rendus* (September 22 and November 24, 1862), and *Revue des Travaux Scientifiques de Léon Foucault* (2 vols., 4to, Paris, 1878). Cornu's determination is found in *Annales de l'Observatoire de Paris, Mémoires*, vol. xiii. The works of Michelson and Newcomb are published in *extenso* in the *Astronomical Papers of the American Ephemeris*, vols. i. and ii. (S. N.)

**LIGHTFOOT, John** (1662-1675), English divine and rabbinical scholar, was the son of Thomas Lightfoot, vicar of Uttotezer, Staffordshire, and was born at Stoke-upon-Trent on April 10, 1662, the son of Thomas Lightfoot and his wife, Ann, daughter of William and Mary Morton Green near Congleton, Cheshire, and at Christ's College, Cambridge, where he was reckoned the best orator among the undergraduates. After taking his degree he became assistant master at Repton in Derbyshire; after taking orders he was appointed curate of Norton-under-Hales in Shropshire. There he attracted the notice of Sir Rowland Cotton, an amateur Hebraist of some distinction, who made him his domestic chaplain at Bellaport. Shortly after the removal of Sir Rowland to London, Lightfoot, abandoning an intention to go abroad, accepted a charge at Stone in Staffordshire, where he continued for about two years. From Stone he removed to Hornsey, near London, for the sake of reading in the library of Sion College. His first published work, entitled *Erubhim, or Miscellaneous, Christian and Judicial, penned for recreation at vacant hours*, and dedicated to Sir R. Cotton, appeared at London in 1674. In September 1673 he was presented by Sir R. Cotton to the rectory of Ashley in Staffordshire, where he remained until June, 1643, when he went to London, probably to superintend the publication of his next work, *A Few and New Observations upon the Book of Genesis: the most of them certain; the rest, probable; all, harmless, strange and rarely heard of before*, which appeared at London in that year. Soon after his arrival in London he became minister of St Bartholomew's church, near the Exchange; and in 1643 he was appointed to preach the sermon before the House of Commons on occasion of the public fast of the 29th of March. It was published under the title of *Elia Redivius*, the text being Luke i. 17; in it a parallel is drawn between the Baptist's ministry and the work of reformation which in the preacher's judgment was incumbent on the parliament of his own day.

Lightfoot was also one of the original members of the Westminster Assembly; his *Journal of the Proceedings of the Assembly of Divines* from January 1, 1643 to December 31, 1644, now printed in the thirteenth volume of the 5vo edition of his *Works*, is a valuable historical source for the brief period to which it relates. He was assiduous in his attendance, and, though frequently standing almost or quite alone, especially in the Erastian controversy, he exercised a material influence on the result of the discussions of the Assembly. In 1643 Lightfoot published *A Handful of Gleanings out of the Book of Exodus*, and in the same year he was made master of Catharine Hall by the parliamentary visitors of Cambridge, and also, on the recommendation of the Assembly, was promoted to the rectory of Much Munden in Hertfordshire; both appointments he retained until his death. In 1644 was published in London the first instalment of the laborious but never completed work of which the full title runs *The Harmony of the Four Evangelists among themselves, and with the Old Testament, with an explanation of the chiefest difficulties both in Language and Sense*: Part I. From the beginning of the Gospels to the Baptism of our Saviour. The second part *From the Baptism of our Saviour to the first Passover after followed in 1647, and the third From the first Passover after our Saviour's Baptism to the second in 1650*. On the 26th of August 1645 he again preached before the House of Commons on the day following. His text was Rev. xx. 1, 2. After contending the doctrine of the Millenaries, he urged various practical suggestions for the repression with a strong hand of current blasphemies, for a thorough revision of the authorized version of the Scriptures, for the encouragement of a learned ministry, and for a speedy settlement of the church. In the same year appeared *A Commentary upon the Acts of the Apostles, chronicl...* the text explained, and the times of the *Story cast into annals*. From the beginning of the Book to the end of the Twelfth Chapter. With a brief survey of the contemporary Story of the Jews and Romans (down to the third year of Claudius). In 1647 he published *The Harmony, Chronicle, and Order of the Old Testament*, which was followed in 1653 by *The Harmony, Chronicle, and Order of the New Testament*, inscribed to Cromwell. In 1654 Lightfoot had been chosen vice-chancellor of the university of Cambridge, but continued to reside by preference at London. Shortly before the death of Catharine Hall, he was confirmed at the Restoration. The remainder of his life was devoted to helping Brian Walton with the Polyglot Bible (1657) and to his own best-worked, the *Horae Hebraicae et Talmudicae*, in which the volume relating to Matthew appeared in 1658, that relating to Mark in 1663, and those relating to 1 Corinthians, John and Luke, in 1664, 1671 and 1674 respectively. While travelling from Cambridge to Ely where he had been collated in 1668 by Sir Orlando Bridgman to a prebendal stall, he caught a severe cold, and died at Ely on the 6th of December 1675. The *Horae Hebraicae et Talmudicae impensa in Acta Apostolorum et in Ep. S. Pauli ad Romans* were published posthumously.

The *Works of Lightfoot* were first edited, in 2 vols. fol., by G. Bright and Strype in 1684; the *Opera Omnia*, cura Joh. Testelii, appeared at Rotterdam in 1686 (2 vols. fol.), and again, edited by J. Leusden, at Franeker in 1699 (3 vols. fol.). A volume of *Remains* was published at London in 1706. The *Hor. Hebr. et Talm.* were translated into Latin by Carpenter (Leipzig, 1675-1705), and again, in English, by Gandell (Oxford, 1859). The most complete edition is that of the *Whole Works*, in 13 vols. 8vo, edited, with a life, by R. Pitman (London, 1822-1825). It includes, besides the works mentioned, numerous sermons, letters and miscellaneous writings; and also *The Temple*, especially as it stood in the Days of our Saviour (London, 1850).

**LIGHTFOOT, Joseph Barber** (1825-1880), English theologian and bishop of Durham, was born at Liverpool on the 13th of April 1825. His father was a Liverpool accountant. He was educated at King Edward's school, Birmingham, under James Prince Lee, afterwards bishop of Manchester, and had as contemporaries B. F. Westcott and E. W. Benson. In 1847 Lightfoot went up to Trinity College, Cambridge, and there read for his degree with Westcott. He graduated senior classic and 30th wrangler, and was elected a fellow of his college. From 1847 to 1850 he edited the *Journal of Classical and Sacred Philology*. In 1857 he became tutor and his fame as a scholar grew rapidly. He was made Hulsean professor in 1861, and shortly afterwards chaplain to the Prince Consort and honorary chaplain in ordinary to the Queen. In 1866 he was Whitehall
preacher, and in 1871 he became canon of St. Paul's. His sermons were not remarkable for eloquence, but a certain solidity and balance of judgment, an absence of partisanship, a sobriety of expression combined with clearness and force of diction, attracted hearers and inspired them with confidence. As was written of him in The Times after his death, "his personal character carried immense weight, but his great position depended still more on the universally recognized fact that his belief in Christian truth and his defence of it were supported by learning as solid and comprehensive as could be found anywhere in Europe, and by a temper not only of the utmost candour but of the highest scientific capacity. The days in which his university influence was asserted were a time of much shaking of old beliefs. The disintegrating speculations of an influential school of criticism in Germany were making their way among English men of culture just about the time, as is usually the case, when the tide was turning against them in their own country. The peculiar service which was rendered at this juncture by the 'Cambridge School' was that, instead of opposing a mere dogmatic opposition to the Tübingen critics, they met them frankly on their own ground; and instead of arguing that their conclusions ought not to be and could not be true, they simply proved that their facts and their premises were wrong. It was a characteristic of equal importance that Dr Lightfoot, like Dr Westcott, never discussed these subjects in the mere spirit of controversy. It was always patent that what he was chiefly concerned with was the substance and the life of Christian truth, and that his whole energies were employed in this inquiry because his whole heart was engaged in the truths and facts which were at stake. He was not diverted by controversy to side-issues; and his labour was devoted to the positive elucidation of the sacred documents in which the Christian truth is enshrined."

In 1872 the anonymous publication of Supernatural Religion created considerable sensation. In a series of masterly papers in the Contemporary Review, between December 1872 and May 1877, Lightfoot successfully undertook the defence of the New Testament canon. The articles were published in collected form in 1889. About the same time he was engaged in contributions to W. Smith's Dictionary of Christian Biography and Dictionary of the Bible, and he also joined the committee for revising the translation of the New Testament. In 1875 he became Lady Margaret professor of divinity in succession to William Selwyn. He had previously written his commentaries on the epistles to the Galatians (1865), Philippians (1868) and Colossians (1875), the notes to which were distinguished by sound judgment and enriched from his large store of patristic and classical learning. These commentaries may be described as to a certain extent a new departure in New Testament exegesis. Before Lightfoot's time, especially on the epistles, had not infrequently consisted either of short homilies on particular portions of the text, or of endeavours to enforce foregone conclusions, or of attempts to decide with infinite industry and ingenuity between the interpretations of former commentators. Lightfoot, on the contrary, endeavoured to make his author interpret himself, and by considering the general drift of his argument to discover his meaning where it appeared doubtful. Thus he was able often to recover the meaning of a passage which had been buried under a heap of contradictory glosses, and he founded a school in which sobriety and common sense were added to the industry and ingenuity of former commentators. In 1879 Lightfoot was consecrated bishop of Durham in succession to C. Baring. His moderation, good sense, wisdom, temper, firmness and erudition made him as successful in this position as he had been when professor of theology, and he speedily surrounded himself with a band of scholarly young men. He endeavoured to combine his habits of theological study with the practical work of administration. He exercised a large liberality and did much to further the work of temperance and purity organizations. He continued to work at his editions of the Apostolic Fathers, and in 1885 published an edition of the Epistles of Ignatius and Polycarp, collecting also a large store of valuable materials for a second edition of Clement of Rome, which was published after his death (1st ed., 1869). His defence of the authenticity of the Epistles of Ignatius is one of the most important contributions to that very difficult controversy. His unremitting labours impaired his health and shortened his splendid career at Durham. He was never married. He died at Bournemouth on the 21st of December 1889, and was succeeded in the episcopate by Westcott, his schoolfellow and lifelong friend.

Four volumes of his Sermons were published in 1890.

Lighthouse, a form of building erected to carry a light for the purpose of warning or guidance, especially at sea.

1. Early History.—The earliest lighthouses, of which records exist, were the towers built by the Libyans and Cushites in Lower Egypt, beacon fires being maintained in some of them by the priests. Lesches, a Greek poet (c. 666 B.C.) mentions a lighthouse at Sigeum (now Cape Inchisari) in the Troad. This appears to have been the first light regularly maintained for the guidance of mariners. The famous Pharos of Alexandria, built by Sostratus of Cnidus in the reign of Ptolemy I. (280-264 B.C.), was regarded as one of the wonders of the world. The tower, which took its name from that of the small island on which it was built, is said to have been 60 ft. in height, but the evidence in support of this statement is doubtful. It was destroyed by an earthquake in the 13th century, but remains are said to have been visible as late as 1530. The name Pharos became the general term for all lighthouses, and the term "pharology" has been used for the science of lighthouse construction.

The tower at Ostia was built by the emperor Claudius (A.D. 50). Other famous Roman lighthouses were those at Ravenna, Ponzioi and Messina. The ancient Pharsos at Dover and that at Boulogne, later known as the Tour d'Ordre, were built by the Romans and were probably the earliest lighthouses erected in western Europe. Both are now demolished.

The light of Cordouan, on a rock in the sea at the mouth of the Gironde, is the earliest example now existing of a wave-swept tower. Earlier towers on the same rock are attributed to Louis le Debonnaire (c. A.D. 865) and the second to Edward the Black Prince. The existing structure was begun in 1584 during the reign of Henri II. of France and completed in 1611. The upper part of the beautiful Renaissance building was removed towards the end of the 18th century and replaced by a loftier cylindrical structure rising to a height of 207 ft. above the rock and with the focal plane of the light 196 ft. above high water (fig. 1). Until the 18th century the light exhibited from the tower was from an oak log fire, and subsequently a coal fire was in use for many years. The ancient tower at Corunna, known as the Pillar of Hercules, is supposed to have been a Roman Pharos. The Torre del Capo at Genoa originally stood on the promontory of San Berrique. It was built in 1139 and first used as a lighthouse in 1326. It was rebuilt on its present site in 1643. This beautiful tower rises 235 ft. above the cliff, the light being elevated 354 ft. above sea-level. A lens light was first installed in 1841. The Pharos of Meloria was constructed by the Pisans in 1154 and was several times rebuilt until finally destroyed in 1290. On the abandonment of Meloria by the Pisans, they erected the still existing tower at Leghorn in 1297.

In the 17th and 18th centuries numerous towers, on which were erected braziers or grates containing wood or coal fires, were established in various positions on the coasts of Europe. Among such stations in the United Kingdom were Tynemouth (c. 1608), the Isle of May (1636), St. Agnes (1680), St. Bees (1718) and the Lizard (1751). The oldest lighthouse in the United States is believed to be the Boston light situated on Little Brewster Island on the south side of the main entrance to Boston Harbour, Mass. It was established in 1716, the present structure dating from 1859. During the American War of Independence the lighthouse suffered many vicissitudes and was successively destroyed and rebuilt three times by the American or British
forces. At the third rebuilding in 1783 a stone tower 68 ft. in height was erected, the illuminant consisting of four oil lamps. Other early lighthouse structures on the New England coast were those at Beaver Tail, near the entrance to Newport Harbour (1740), and the Brant at the entrance to Nantucket Harbour (1754). A watch-house and beacon appear to have been erected on Beacon or Lighthouse Island as well as on Point Allerton Hill near Boston, prior to 1673, but these structures would seem to have been in the nature of look-out stations in time of war rather than lighthouses for the guidance of mariners.

2. Lighthouse Structures.—The structures of lighthouses may be divided into two classes, (a) those on rocks, shoals or in other situations exposed to the force of the sea, and (b) the more numerous class of land structures.

Wave-swept Towers.—In determining the design of a lighthouse tower to be erected in a wave-swept position consideration must be given to the physical features of the site and its surroundings. Towers of this description are classified as follows: (1) Masonry and concrete structures; (2) Openwork steel and iron-framed erections on pile or other foundations; (3) Cast iron plated towers; (4) Structures erected on cylinder foundations.

(1) Masonry Towers.—Masonry or concrete towers are generally preferred for erection on wave-swept rocks affording good foundation, and have also been constructed in other situations where adequate foundations have been made by sinking caissons into a soft sea bed. Smeaton's tower on the Eddystone Rock is the model upon which most later designs of masonry towers have been based, although many improvements in detail have since been made. In situations of great exposure the following requirements in design should be observed: (a) The centre of gravity of the tower structure should be as low as possible. (b) The mass of the structure superimposed at any horizontal section must be sufficient to prevent its displacement by the combined forces of wind and waves without dependence on the adhesion at horizontal joint faces or on the dovetailing of stones introduced as an additional safeguard. (c) The structure should be circular in plan throughout, this form affording the least resistance to wave stroke and wind pressure in any direction.

(d) The lower portion of the tower exposed to the direct horizontal stroke of the waves should, for preference, be constructed with vertical face. The upper portion to be either straight with uniform batter or continuously curved in the vertical plane. External projections from the face of the tower, except in the case of a gallery under the lantern, should be avoided, the surface throughout being smooth. (e) The height from sea-level to the top of the tower should be sufficient to avoid the obscuration of the light by broken water or dense spray driving over the lantern. (f) The foundation of the tower should be carried well into the solid rock. (g) The materials of which the tower is built should be of high density and of resistant nature. (h) The stones used in the construction of the tower, at any rate those on the outer face, should be dovetailed or joggled one to the other in order to prevent their being dislodged by the sea during the process of construction and as an additional safeguard of stability. Of late years, cement concrete has been used to a considerable extent for maritime structures, including lighthouses, either alone or faced with masonry.

(2) Openwork Structures.—Many examples of openwork steel and iron lighthouses exist. Some typical examples are described hereafter. This form of design is suitable for situations where the tower has to be carried on a foundation of iron or steel piles driven or screwed into an insecure or sandy bottom, such as on shoals, coral reefs and sand banks or in places where other materials of construction are exceptionally costly and where facility of erection is a desideratum.

(3) Cast iron Towers.—Cast iron plated towers have been erected in many situations where the cost of stone or scarcity of labour would have made the erection of a masonry tower excessively expensive.

(4) Caisson Foundations.—Cylinder or caisson foundations have been used for lighthouse towers in numerous cases where such structures have been erected on sand banks or shoals. A remarkable instance is the Rothersand Tower. Two attempts have been made to sink a caisson in the outer Diamond Shoal off Cape Hatters on the Atlantic coast of the United States, but these have proved futile. The following are brief descriptions of the more important wave-swept towers in various parts of the world.

Eddystone (Winstanley's Tower).—The Eddystone rocks, which lie about 14 m. off Plymouth, are fully exposed to southwest seas. The rocks are submerged at high water of spring tides. Four towers have been constructed on the reef. The first lighthouse (fig. 2) was polygonal in plan and highly ornamented with galleries and projections which offered considerable resistance to the sea stroke. This structure was begun by Henry Winstanley, a gentleman of Essex, in 1694. In 1698 it was finished to a height of 80 ft. to the wind vane and the light exhibited, but in the following year, in consequence of damage by storms, the tower was increased in diameter from 4 ft. to 8 ft. by being filled solidly below a height of 20 ft. and made solid to a height of 120 ft. The work was completed in the year 1709. The lower part of the structure appears to have been of stone, the upper part and lantern of timber. During the great storm of the 20th of November 1703 the tower was swept away, those in it at the time, including the builder, being drowned.

Eddystone (Rudyard's Tower, fig. 3).—This structure was begun in 1756 and completed in 1764. It was a frustum of a 20 ft. 8 in. diameter at the base and 14 ft. 3 in. at the top. The tower was 92 ft. in height to the top of the lantern. The work consisted principally of oak timbers securely bolted and cramped together, the dovetailing filling in solid with stone, while the height of the structure. The simplicity of the design and the absence of projections from the outer face rendered the tower very suitable to withstand the onslight of the waves. The lighthouse was destroyed by fire in 1775.

Eddystone (Smeaton's Tower, fig. 4).—This famous work, which consisted entirely of stone, was begun in 1756, the light being first exhibited in 1759. John Smeaton was the first engineer to use dovetailed joints for the stones in a lighthouse structure, and those stones, which averaged 1 ton in weight, were fastened to each other by means of dovetailed vertical joint faces, oak key wedges, and by oak tree-nails wedged top and bottom, extending vertically from every course into the stones beneath it. During the 19th century the tower was strengthened on two occasions by the addition of heavy wrought iron ties, and the overhanging cornice was reduced in diameter to prevent the waves from lifting the stones from their beds. In 1877, owing partly to the undermining of the rock on which the tower was built and the insufficient height of the structure,
the Corporation of Trinity House determined on the erection of a new lighthouse in place of Smeaton's tower.

**Eddystone, New Lighthouse (J. N. Douglass).**—The site selected for the new tower is 120 ft. S.S.E. from Smeaton's lighthouse, where a suitable foundation was found, although a considerable section of the lower courses had to be laid below the level of low water. The vertical base is 44 ft. in diameter and 22 ft. in height. The tower (figs. 5 and 6) is a concave elliptic frustum, and is solid, with the exception of a fresh-water tank, 10 ft. high of 25 ft. 6 in. above high-water level. The walls above this level vary in thickness from 8 ft. 6 in. to 2 ft. 3 in. under the gallery. All the stones are dovetailed, both horizontally and vertically, on all joint faces, the stones of the foundation course being secured to the rock by Muntz metal bolts. The tower contains 62,133 cub. ft. of granite, weighing 4668 tons. The height of the structure from low water ordinary spring tides to the mean focal plane is 149 ft. and it stands 133 ft. above high water. The lantern is a cylindrical helically framed structure with domed roof. The astragals are of gunmetal and the pedestal of cast iron. The optical apparatus consists of two superposed tiers of refracting lens panels, 12 in each tier of 920 mm. focal distance. The lenses subtend an angle of 92° vertically. The 12 lenz panels are arranged in groups of two, thus producing a group in that the stones forming the floor consisted of corbelled stone arches built into the wall and constituting solid portion of the tower. The tower floors consisted of stone arches, the thrust being taken by the walls of the tower itself, which were strengthened for the purpose by building in chains in the form of hoops (fig. 7). The system of constructing corbelled stone floors was first adopted by R. Stevenson in the Bell Rock lighthouse (fig. 8).

**Bell Rock Lighthouse (fig. 9).**—The Bell Rock, which lies 12 m. off the coast of Forfarshire, is exposed to a considerable extent at low water. The tower is submerged to a depth of about 16 ft. at high water of spring tides. The rock is of hard sandstone. The lighthouse was constructed by Robert Stevenson and is 100 ft. in height, the solid portion being carried to a height of 21 ft. above high water. The work of construction was begun in 1807, and finished in 1811. The total weight of the tower is 2076 tons. A new lantern and dioptric apparatus were erected on the tower in 1902. The focal plane of the light is elevated 93 ft. above high water.

**Smeaton's Lighthouse (fig. 10).**—The Smeaton's Lighthouse, 12 m. off the island of Lyree in Argyllshire, are wholly open to the Atlantic.

The work, designed by Alan Stevenson, was begun in 1838 and finished in 1844. The tower, the profile of which is a hyperbolic curve, is 138 ft. high to the lantern base, 42 ft. diameter at the base, and 16 ft. at the top. Its weight is 4308 tons. The structure contains 9 rooms in addition to the lantern chamber. It is solid to a height of 26 ft. above the base.

**Heaux de Brehé Lighthouse.**—The reef on which this tower is constructed lies off the coast of Brittany, and is submersed at high tide. The reef is 75° in plan with a gallery at a height of about 20 ft. above the base. The tower is 156 ft. in height from base to lantern floor. It is solid to a height of 225 ft. above the base.

**Haut Banc du Nord Lighthouse.**—This tower is placed on a reef at the north-west extremity of the Île de Ré, and was constructed in 1839-1853.

**Bishop Rock Lighthouse.**—The Lighthouse on the Bishop Rock, which is the westernmost landfall rock of the Scilly Isles, occupies perhaps a more exposed situation than any other in the world.
The first lighthouse erected was in 1847 under the direction of N. Douglass. The tower consisted of a cast and wrought iron openwork structure having the columns deeply sunk into the rock. On the 5th of February 1850, when the tower was ready for erection of the lantern and illuminating apparatus, a heavy storm swept away the whole of the structure. This tower was designed for an elevation of 94 ft. to the focal plane. In 1851 the erection of a granite tower, from the designs of James Walker, was begun. This light was first exhibited in 1858. The tower (fig. 11) had an elevation to the focal plane of 110 ft., the lower 14 courses being arranged in steps, or offsets, to break up the force of the waves. This structure also proved insufficient to withstand the very heavy seas to which it was exposed. Soon after its completion the 5-cwt. fog bell, fixed to the lantern gallery 100 ft. above high-water mark, was washed away, together with the flagstaff and ladder. The tower vibrated considerably during storms, and it was found that some of the external blocks of granite had been split by the excessive stress to which they had been exposed. In 1874 the tower was strengthened by bolting continuous iron ties to the interior surfaces of the walls. In 1881, when further signs of damage appeared, it was determined to remove the upper storey or service room of the lighthouse, and to case the structure from its base upwards with granite blocks securely dovetailed to each other and to the existing work. At the same time it was considered advisable to increase the elevation of the light, and place the main focal plane of the new apparatus at an elevation of 146 ft., above high-water mark. The work was begun in 1883, and the new apparatus was first illuminated on the 25th of October 1887. During the operation of heightening the tower it was necessary to install a temporary light, consisting of a cylindrical lightship lantern with catoptric apparatus; this was raised from time to time in advance of the structure as the work proceeded. The additional masonry built into the tower amounts approximately to 3,200 tons. Profiting by the experience gained after the completion of the new Edystone tower, Sir J. Rattray and Douglass decided to build the lower portion of the improved Bishop Rock tower in the form of a cylinder, but with considerably increased elevation (figs. 12 and 13). The cylindrical base is 40 ft. in diameter, and rises in 7-ft. octagonal steps. The superstructure is cylindrical and helically framed, 14 ft. in diameter, in the plane of the horizon. The optical apparatus consists of two superposed tiers of lenses of 1350 mm. focal distance, the lenses subtending a horizontal angle of 30° and a vertical angle of 80°. The apparatus consists of 5 groups of lenses each group producing a double flaring light of one minute period, the whole apparatus revolving once in five minutes. The maximum aggregate candle-power of the flash is 62,000 candles. A gun-cotton explosive fog signal is attached to the lantern. The cost of the various lighthouses on the Bishop Rock has been as follows:

1. Cast iron lighthouse .................................................. £11,500
2. Granite lighthouse .................................................. 34,559
3. Improved granite lighthouse ...................................... 64,889

The Smalls Lighthouse.—A lighthouse has existed on the Smalls rock, 18½ m. off Milford Haven, since 1776, when an oak pile structure was erected by Henry Whiteside. The existing structure, after the model of the second lighthouse on the Bishop Rock, was erected in 1856-1861 by the Trinity House and is 114 ft. in height from the foundation to the lantern floor. A new optical apparatus was installed in 1907.

Minot's Ledge Lighthouse.—The tower, which is 89 ft. in height, is built of granite upon a rock at Latitude 42° 12' N., Mass., and occupied five years in construction, being completed in 1862 at a cost of about $400,000.

The rock just bares at low water. The stones are dovetailed vertically but not on their horizontal beds in the case of the lower 40 ft. or solid portion of the tower, the dovetail being substituted for the horizontal dovetailed joints used in the case of the Wolf and other English towers. The shape of the tower is a monolithic fluted column.

Wolf Rock Lighthouse.—This much exposed rock lies midway between the Scilly Isles and the Lizard Point, and is situated about the south of Mull, which is the nearest shore. The maximum diameter of the tower (fig. 15), which is of parabolic outline, is 36 ft., decreasing to 16 ft. before the shaft is about 6 ft. above the rock; the masonry weighs 3115 tons, of which 1810 are contained in the solid part. This tower occupied seven years in erection, and was completed in 1872.

Great Basses Lighthouse, Ceylon.—The Great Basses light lighthouse lies 6 m. from the coast of Java, and is 32 ft. in diameter, above which is a tower 67½ ft. in high and 23 ft. in diameter. The walls vary in thickness from 5 ft. to 2 ft. The tower, including the base, contains about 2760 tons. The work was finished in three years, 1867-1869.

Spectacle Reef Lighthouse, Lake Irwin.—This is a structure similar to that on Minot’s ledge, standing on a limestone reef at the northern end of the lake. The tower (fig. 16) was constructed with a view to withstanding the effects of ice masses in the soundings, which is from 20 to 40 ft. deep, and 25 to 30 ft. in thickness at the bottom. The tower is 67½ ft. in diameter, with a focal plane of 69½ ft., and weighs 7600 tons. The cost amounted to approximately £78,000.

Chicken Rock Lighthouse.—The Chicken Rock lighthouse is on the Calf of Man. The curve of the tower, which is 158½ ft. high, is hyperbolic, the diameter varying from 42 ft. to 16 ft. The lower 30 ft. are covered with a concrete base, 5 ft. high. The tower is 32 ft. in diameter, at the base and 93 ft. in height. The focal plane is about 150 ft., and the tower is 69½ ft. in thickness. The work was begun in 1869 and completed in 1874.

Ar’men Lighthouse.—The masonry tower, erected by the French Lighthouse Service, on the Ar’men Rock off the western extremity of the island of Sein, Finistère, occupied fifteen years in erection (1867-1882). The rock is of small area, barely uncovered at low water, and it was therefore found impossible to construct a tower having a base diameter greater than 24 ft. The focal plane of the tower is 52 ft., above the high-water mark (fig. 17).

St George’s Reef Lighthouse, California.—This structure consists of a square pyramidal stone tower rising from the easterly end of an oval masonry pier, built on a rock to a height of 60 ft. above the water. The focal plane is 60½ ft. above the water, and the tower is 86½ ft. above high water. The site is an exceedingly dangerous one, and the work, which was completed in 1891, cost approximately £14,400.

Rattray Head Lighthouse.—This lighthouse was constructed during the years 1857-1862. The tower is cylindrical, 89 ft. high, with a cylindrical light. The foundation consists of a cylindrical cast iron tower 86 ft. in height on the summit of the rock, which was considerably undermined. It was subsequently determined to proceed with the erection of a granite structure of increased height and founded upon a sound ledge of rock on one side of the higher, but now considerably undermined.
Fig. 13.—Bishop Rock Lighthouse.

portation of the reef. This lighthouse tower has its foundation laid near high-water level. The focal plane is at a level of 158 ft. above high-water mark. The cost of the structure, which was commenced in 1899 and completed in 1904, was £79,000.

Beechy Head Lighthouse.—A lighthouse has been erected upon the foreshore at the foot of Beechy Head, near Eastbourne, to replace the old structure on the cliff having an elevation of 284 ft. above high-water mark. Experience proved that the light of the latter was frequently obscured by banks of mist or fog, while at the lower level the transparency of the atmosphere was considerably less impaired. The Trinity House therefore decided in the year 1899 to proceed with the construction of a granite tower upon the foreshore at a distance of some 570 ft. from the base of the cliff (fig. 18). The foreshore at this point consists of chalk, and the selected site just abuts at low water ordinary spring tides. The foundation course was laid at a depth of 10 ft. below the surface, the area being excavated within a coffer-dam. The tower, which is 47 ft. in diameter at the base, has an elevation to the focal plane above high-water mark of 103 ft., or a total height from foundation course to gallery coping of 123 ft. 6 in. The lower or solid portion of the tower has its face stones constructed in vertical offsets or steps in a similar manner to that adopted at the Wolf Rock and elsewhere. The tower is constructed with a façade of granite, all the stones being dovetailed in the usual manner. The heating of the base is largely composed of concrete.

The work was completed in 1902 and cost £56,000.

Maplin Lighthouse.—The screw pile lighthouse erected on the Maplin Sands in the estuary of the river Thames in 1838 is the earliest of its kind and served as a model for numerous similar structures in various parts of the world. The piles are nine in number, 5 in. diameter of solid wrought iron with screws 6 ft. diameter (fig. 19).

Bishop Rock Lighthouse, Florida.—This iron structure, which was begun in 1875 and completed in 1878, stands on the extreme northern point of the Florida reefs. The height of the tower, which is founded on wrought iron piles driven 10 ft. into the coral rock, is 110 ft. from high water to focal plane. The ironwork pyramid structure encloses a plated iron dwelling for the accommodation of the keepers.

The cost of construction amounted to £42,000.

Alligator Reef Lighthouse, Florida.—This tower is one of the finest iron sea-swept lighthouse structures in the world. It consists of a pyramidal iron framework 135 ft. 6 in. in height, standing on the Florida Reef in 5 ft. of water. The cost of the structure, which is similar to the Fowey Rocks tower, was £37,000.

American Shoal Lighthouse, Florida.—This tower (fig. 20) is typical of the openwork pile structures on the Florida reefs and was completed in 1880. The focal plane of the light is at an elevation of 100 ft. above high water.

Wolf Trap Lighthouse.—This building was erected during the years 1868-1870 on Wolf Trap Spit in Chesapeake Bay, near the site of the old openwork structure which was swept away by ice early in 1893. The new tower is formed upon a cast iron caisson 30 ft. in diameter sunk 18 ft. into the sandy bottom. The depth of water on the shoal is 15 ft. at low and 8 ft. at high. The caisson was fitted with concrete, and is surmounted by a brick superstructure 52 ft. in height from low water to the focal plane of the light. A somewhat similar structure was erected in 1885-1887 on the Fourteen Foot Bank in Delaware Bay, at a cost of £24,700. The foundation in this case was, however, shifting sand, and the caisson was carried to a greater depth.

Rothersand Lighthouse.—This lighthouse, off the entrance to the river Weser (Germany), is a structure of great interest on account of the difficulties met with in its construction. The tower had to be founded on a bottom of shifting sand 20 ft. below low water and in a very exposed situation. Work was begun in May 1881, when attempts were made to sink an iron caisson under pneumatic pressure. Owing to the enormous scour removing the sand from one side of the caisson it was necessary to lower it, and eventually it was sunk to a level of 70 ft. below low-water mark. In October of the same year the whole structure collapsed. Another attempt, made in May 1883, to sink a caisson of bi-convex shape in plan 47 ft. long, 37 ft. wide, and 59 ft. in height, met with success, and after much difficulty the structure was sunk to a depth of 73 ft. below low water, the sides being raised by the addition of iron plating as the caisson sank. The sand was removed from the interior by suction. Around the caisson foundation were placed 74,000 cu. yds. of mattress work and stones, the interior being filled with concrete. Towards the end of 1885 the lighthouse was completed, at a total cost, including the first attempt, of over £65,000. The tower is an iron structure in the shape of a concave elliptic frustum, its base being founded upon the caisson foundation at about half-tide level (fig. 21). The light is electric, the current being supplied by cable from the shore. The focal plane is 78 ft. above high water or 109 ft. from the sand level. The total height from the foundation of the caisson to the top of the vane is 185 ft.

Other famous wave-swept towers are those at Haulbowline Rock (Carriford Lough, Ireland, 1823); Horsburgh (Singapore, 1851); Bayes d'Olonne (Bay of Biscay, 1861); Hanois (Alderney, 1862); Dade Island, iron tower (Red Sea, 1863); Alguada Reef, iron tower (Bay of Bengal, 1865); Longships (Land's End, 1872); the Prongs (Bomba, 1874); Little Basses (Ceylon, 1878); the Graves (Boston, U.S.A.,
1905): Jument d’Ouessant (France, 1907); and Roche Bonne (France, building 1910).

**Jointing of Stones in Rock Towers.**—Various methods of jointing the stones in rock towers are shown in figs. 6 and 22. The great distinction between the towers built by successive engineers to the Trinity House and other rock lighthouses is that, in the former the stones of each course are dovetailed together both laterally and vertically and are not connected by metal or wooden pins and wedges and dowled as in most other cases. This dovetail method was first adopted at the Hanois Rock at the suggestion of Nicholas Douglass. On the upper face, one side and at one end of each block is a dovetailed projection. On the under face and the other side and end, corresponding dovetailed recesses are formed with just sufficient clearance for the raised bands to enter in setting (fig. 23). The cement mortar in the joint formed between the faces so locks the dovetails that the stones cannot be separated without breaking (fig. 24).

**Effect of Waves.**—The wave stroke to which rock lighthouse towers are exposed is often considerable. At the Dhu Heartach, during the erection of the tower, 14 joggled stones, each of 2 tons weight, were washed away after having been set in cement at a height of 37 ft. above high water, and similar damage was done during the construction of the Bell Rock tower. The effect of waves on the Bishop Rock and Eddystone towers has been noted above.

**Land Structures for Lighthouses.**—The erection of lighthouse towers and other buildings on land presents no difficulties of construction, and such buildings are of ordinary architectural character. It will therefore be unnecessary to refer to them in detail. Attention is directed to the Phare d’Eckmühl (Finistère), completed in 1897. The cost of this magnificent structure, 207 ft. in height from the ground, was largely defrayed by a bequest of £12,000 left by the marquis de Blocqueville. It is constructed entirely of granite, and is octagonal in plan. The total cost of the tower and other lighthouse buildings amounted to £16,000.

The tower at Île Vierge (Finistère), completed in 1902, has an elevation of 247 ft. from the ground level to the focal plane, and is probably the highest structure of its kind in the world.

The brick tower, constructed at Spurn Point, at the entrance to the Humber and completed in 1895, replaced an earlier structure erected by Smeaton at the end of the 18th century. The existing tower is constructed on a foundation consisting of concrete cylinders sunk in the shingle beach. The focal plane of the light is elevated 120 ft. above high water.

Besides being built of stone or brick, land towers are frequently
OPTICAL APPARATUS

Lighthouse

constructed of cast iron plates or open steel-work with a view to economy. Fine examples of the former are to be found in many British colonies and elsewhere, that on Dassen Island (Cape of Good Hope), 105 ft. in height to the focal plane, being typical (fig. 25). Many openwork structures up to 200 ft. in height have been built. Recent examples are the towers erected at Cape San Thomé (Brazil) in 1882, 145 ft. in height (fig. 26), Mocha (Red Sea) in 1903, 180 ft. and Sanganee Reef (Red Sea) 1906, 165 ft. in height to the focal plane.

3. Optical Apparatus.—Optical apparatus in lighthouses is required for one or other of three distinct purposes: (1) the concentration of the rays derived from the light source into a belt of light distributed evenly around the horizon, condensation in the vertical plane only being employed; (2) the concentration of the rays both vertically and horizontally into a pencil or cone of small angle directed towards the horizon and caused to revolve about the light source as a centre, thus producing a flashing light; and (3) the concentration of the light in the vertical plane and also in the horizontal plane in such a manner as to concentrate the rays over a limited azimuth only.

Apparatus falling under the first category produce a fixed light, and further distinction can be provided in this class by mechanical means of occultation, resulting in the production of an occulting or intermittent light. Apparatus included in the second class are usually employed to produce flashing lights, but sometimes the dual condensation is taken advantage of to produce a fixed pencil of rays thrown towards the horizon for the purpose of marking an isolated danger or the limits of a narrow channel. Such lights are best described by the French term feux de direction. Catoptric apparatus, by which dual condensation is produced, are moreover sometimes used for fixed lights, the light pencils overlapping each other in azimuth. Apparatus of the third class are employed for sector lights or those throwing a beam of light over a wider azimuth than can be conveniently conveyed by an apparatus of the second class, and for reinforcing the beam of light emergent from a fixed apparatus in any required direction.

The above classification of apparatus depends on the resultant effect of the optical elements. Another classification divides the instruments themselves into three classes: (a) catoptric, (b) dioptric and (c) cata-dioptic.

Catoptric apparatus are those by which the light rays are reflected only from the faces of incidence, such as silvered mirrors of plane, spherical, parabolic or other profile. Dioptric elements are those in which the light rays pass through the optical glass, suffering refraction at the incident and emergent faces (fig. 27). Cata-dioptic elements are combined of the two foregoing and consist of optical prisms in which the light rays suffer refraction at the incident face, total internal reflexion at a second face and again refraction on emergence at the third face (fig. 28).

The object of these several forms of optical apparatus is not only to produce characteristics or distinctions in lights to enable them to be readily recognized by mariners, but to utilize the light rays in directions above and below the horizontal plane, and also, in the case of revolving or flashing lights, in azimuths not requiring to be illuminated for strengthening the beam in the direction of the mariner. It will be seen that the effective condensation in flashing lights is very much greater than in fixed belts, thus enabling higher intensities to be obtained by the use of flashing lights than with fixed apparatus.

Catoptric System.—Parabolic reflectors, consisting of small facets of silvered glass set in plaster of Paris, were first used about the year 1763 in some of the Mersey lights by Mr Hutchinson, then dock master at Liverpool (fig. 29). Spherical metallic reflectors were introduced in France about 1761, followed by parabolic reflectors on silvered copper in 1790 in England and France, and in Scotland in 1803. The earlier lights were of fixed type, a number of reflectors being arranged on a frame or stand in such a manner that the pencils of emergent rays overlapped and thus illuminated the whole horizon continuously. In 1783 the first revolving light was erected at Marstrand in Sweden. Similar apparatus were installed at Conduan (1790), Flamborough Head (1806) and at the Bell Rock (1811). To produce a revolving or flashing light the reflectors were fixed on a revolving carriage having several faces. Three or more reflectors in a face were set with their axes parallel.

A type of parabolic reflector now in use is shown in fig. 30. The sizes in general use vary from 21 in. to 24 in. diameter. These instruments are still largely used for light-vessel illumination, and a few important land lights are at the present time of catoptric type, including those at St Agnes (Scilly Islands), Cromer and St Anthony (Falmouth).

Dioptric System.—The first adaptation of dioptric lenses to lighthouse purposes is probably due to T. Rogers, who used lenses at one of the Portland lighthouses between 1786 and 1790. Subsequently lenses by the same maker were used at Howth, Waterford and the North Foreland. Count Buffon had in 1748 proposed to grind out of a solid piece of glass a lens in steps or concentric zones in order to reduce the thickness to a minimum (fig. 31). Condorcet in 1773 and Sir D. Brewster in 1811 designed built-up lenses consisting of stepped annular rings. Neither of these proposals, however, was intended for lighthouse purposes. In 1822 Augustin Fresnel constructed a built-up annular lens in which the centres of curvature of the different rings receded from the axis according to their distances from the centre, so as practically to eliminate spherical aberration; the only spherical surface being the small central part or "bull's eye" (fig. 32). These lenses were intended for revolving lights only. Fresnel next produced his cylindric refractor or lens belt, consisting
of a zone of glass generated by the revolution round a vertical axis of a medial section of the annular lens (fig. 33). The lens belt condensed and parallelized the light rays in the vertical plane only, while the annular lens does so in every plane. The first revolving light constructed from Fresnel's designs was erected at the Cordouan lighthouse in 1823. It consisted of 8 panels of annular lenses placed round the lamp at a focal distance of 920 mm. To utilize the light, the place of the silvered reflectors previously used above and below the lens elements (fig. 28). The ray Fi falling on the prismatic ring ABC is refracted in the direction r r and meeting the face AB at an angle of incidence greater than the critical, is totally reflected in the direction r e emerging after second refraction in a horizontal direction. Fresnel devised these prisms for use in fixed light apparatus, but the principle was, at a later date, also applied to flashing lights, in the first instance by T. Stevenson. Both the dioptric lens and catadioptric prism invented by Fresnel are still in general use, the mathematical calculations of the great French designer still forming the basis upon which lighthouse opticians work.

Fresnel also designed a form of fixed and flashing light in which the distinction of a fixed light, varied by flashes, was produced by placing panels of straight refracting prisms in a vertical position on a revolving carriage outside the fixed light apparatus. The revolution of the upright prisms periodically increased the power of the beam, by condensation of the rays emergent from the fixed apparatus, in the horizontal plane.

The lens segments in Fresnel's early apparatus were of polygonal form instead of cylindrical, but subsequently manufacturers succeeded in grinding glass in cylindrical rings of the form now used. The first apparatus of this description was of Messrs. Cookson of Newcastle in 1836 at the suggestion of Alan Stevenson and erected at Inchkeith.

In 1825 the French Commission des Phares decided upon the exclusive use of lenticular apparatus for their work. The Scottish Lighthouse Board followed with the Inchkeith revolving apparatus in 1835 and Isle of May fixed optic in 1836. In the latter instrument Alan Stevenson introduced helical frames for holding the glass prisms in place, thus avoiding complete obstruction of the light rays in any azimuth.

The first dioptric light erected by the Trinity House was that formerly at Start Point in Devonshire, constructed in 1836. Catadioptric or reflecting prisms for revolving lights were not used until 1850, when Alan Stevenson designed them for the North Ronaldshay lighthouse.
**DIOPTRIC MIRROR**—The next important improvement in lighthouse optical work was the invention of the dioptric spherical mirror by Mr. (afterwards Sir) J. T. Chance in 1862. The zones or prisms were generated round a vertical axis and divided into segments. This form of mirror is still in general use (figs. 36 and 37).

**AZIMUTHAL CONDENSING PRISMS**—Previous to 1850 all apparatus were designed to emit light of equal power in every azimuth either constantly or periodically. The only exception was where a light was situated on a stretch of coast where a mirror could be placed behind the flame to utilize the rays, which would otherwise pass landward, and reflect them back, passing through the flame and lens. In a seaward direction. In order to increase the intensity of light in certain azimuths T. Stevenson devised his azimuthal condensing prisms which, in various forms and methods of application, have been largely used for the purpose of strengthening the light rays in required directions as, for instance, where coloured sectors are provided. Applications of this system will be referred to subsequently.

**OPTICAL GLASS FOR LIGHTHOUSES**—In the early days of lens lights only glass used for the prisms was made in France at St. Gohn and Premontre works, which have long been celebrated for the high quality of optical glass produced. The early dioptric lights erected in the United Kingdom, some 13 in all, were made by Messrs. Cookson of South Shields, who were instructed by Léonard Fresnel, the brother of Augustin. At first, they tried to mould the lens and then to grind it out of one thick sheet of glass. The successors of the Cookson firm abandoned the manufacture of lenses in 1845, and the firm of Letourneau & Lepautre of Paris again became the monopolists. In 1850 Messrs. Chance Bros. & Co. of Birmingham began the manufacture of optical glass, as did by M. Tabouret, a French expert who had been a colleague of Augustin Fresnel himself. The first light made by the firm was shown at the Great Exhibition of 1851, and then numerous dioptric apparatus have been constructed by Messrs. Chance, who are, at this time, the only manufacturers of lighthouse glass in the United Kingdom. Most of the glass used for apparatus constructed in France is manufactured at St. Gohn. Some of the glass used by German constructors is made at Rathenow in Prussia and Goslar in the Harz.

The glass generally employed for lighthouse optics has for its refractive index a mean value of $\mu=1.51$, the corresponding critical angle being $41^\circ, 30'$. Fresnel Chance have used dense flint glass for the upper and lower refracting rings of high angle lenses and for dioptric mirrors in certain cases. This glass has a value of $\mu=1.62$ with critical angle $38^\circ, 5'$. OCCULTING LIGHTS—During the last 25 years of the 19th century the disadvantages of fixed lights became more and more apparent. At the present day the practice of installing such, except occasionally in the case of the smaller and less important of harbour or river lights, is practically ceased, as the dioptric apparatus is more generally employed. The most distinctive characteristic for every light when possible has led to the conversion of many of the fixed-light apparatus of earlier years into occulting lights, and often to their supercession by more modern and powerful flashing apparatus. An occulting apparatus in general use consists of a cylindrical screen, fitting over a circular tower, and recessed into which the lamp is placed. The lamp is arranged to be successively raised and lowered by means of a cam-wheel at stated intervals. The cam-wheel is actuated by means of a weight or spring clock. Varying characteristics may be procured by means of such a contrivance—single, double, triple or other systems of occultation. The eclipses or periods of darkness are of much the same relation to the times of illumination as do the flashes to the eclipses in a revolving or flashing light. In the case of a first-order fixed light the cost of conversion to an occulting characteristic does not exceed £250 to £300. With apparatus illuminated by gas the occultations may be produced by successively raising and lowering the gas at stated intervals. Another form of occulting mechanism employed consists of a series of vertical screens mounted on a carriage and revolving round the burner. The carriages are rotated on rollers or ball bearings or carried upon a small mercury float. The usual driving mechanism employed is a spring clock. "Otter" screens are used in cases where it is desired to produce different periods of occultations in two or more positions in azimuth in order to differentiate sectors marking shoals, &c. The screens are of sheet metal pierced and arranged vertically, some what in the manner of the laths of a venetian blind, and operated by mechanical means.

**LEADING LIGHTS**—In the case of lights designed to act as a lead through a narrow channel or as direction lights, it is undesirable to employ a flashing apparatus. Fixed-light optics are employed to meet such cases, and are generally fitted with occulting mechanism. A typical apparatus of this description is the lighthouse at Gage Roads, Fremantle, West Australia (fig. 38). The occulting light covers the fairway and is flanked by sectors of occulting red and green light marking dangers and intensified by vertical condensing prisms. A good example of a holophotal direction light was exhibited at the 1000 Paris Exhibition, and afterwards erected at Suzac lighthouse (France). The light consists of an annular lens 500 mm. focal distance, of $180^\circ$ horizontal angle and $137^\circ$ vertical, with a mirror of $180^\circ$ at the back. The lens throws a red beam of about $45^\circ$ amplitude in azimuth, and a green beam of $105^\circ$ amplitudes in the same direction. The intensity is inconsiderable at petroleum vapour burner. Holophotal direction lenses of this type can only be applied where the sector to be marked is of comparatively small angle. Silvered metallic mirrors of parabolic form are also used for the purpose. The use of single direction lights frequently renders the construction of separate towers for leading lights unnecessary.

If two distinct lights are employed to indicate the line of navigation through a channel or between dangers they must be sufficiently far apart to afford a good lead, the front or seaward light being situated at a lower elevation than the rear or landward one.

**COLOURED LIGHTS**—Colour is used as seldom as possible as a distinction, entailing as it does a considerable reduction in the power of the light. It is necessary in some instances for differentiating sectors over dangers and for harbour lighting purposes. The use of coloured lights for alternating flashes for lighthouse lights is not to be condemned, on account of the unequal absorption of the coloured
and bright rays by the atmosphere. When such distinction has been employed, as in the Wolf Rock apparatus, the red and white beams can be approximately equalized in initial intensity by constructing the lens and prism panels for the red light of larger angle than those for the white beams. Owing to the absorption by the red colouring, the power of a red beam is only 40% of the intensity of the corresponding white light. This corresponding intensity of green light is 25%. When red or green sectors are employed they should invariably be reinforced by mirrors, azimuthal condensing prisms, or other means to raise the coloured beam to approximately the same intensity as the white light. With the introduction of group-flashing characteristics the necessity for using colour as a means of distinction disappeared.

High-Angle Vertical Lenses.—Messrs Chance of Birmingham have manufactured lenses having 97° of vertical amplitude, but this result was only attained by using dense flint glass of high refractive index for the upper and lower elements. It is doubtful, however, whether the use of refracting elements for a greater angle than 80° vertically is attended by any material corresponding advantage.

Group Flashing Lights.—One of the most useful distinctions consists in the grouping of two or more flashes separated by short intervals of darkness, the group being succeeded by a longer eclipse. Thus two, three or more flashes, say, half second duration or less follow each other at intervals of about 2 seconds and are succeeded by an eclipse of, say, 10 seconds, the sequence being completed in a period of, say, 15 seconds. In 1874 Dr John Hopkinson introduced the very valuable improvement of dividing the lenses of a dioptric revolving light with the panels of reflecting prisms above and below them, setting them at an angle to produce the group-flashing characteristic. The first apparatus of this type constructed were those now in use at Tampico, Mexico and the Little Basses lighthouse, Ceylon (double flashing). The Casquets apparatus (triple flashing) was installed in 1877. A group-flashing catoptric light had, however, been exhibited from the Royal Sovereign light-vessel in 1875. A sectional plan of the quadruple-flashing first order apparatus at Pendeen in Cornwall is shown in fig. 39; and fig. 55 (Plate I) illustrates a double flashing first order light at Pachena Point in British Columbia. Hopkinson’s system has been very extensively used, most of the group-flashing lights shown in the accompanying tables, being designed upon the general lines he introduced. A modification of the system consists in grouping two or more lenses together separated by equal angles, and filling the remaining angle in azimuth by a reinforcing mirror or screen. A group-flashing distinction was proposed for gas lights by J. R. Wigham of Dublin, who obtained it in the case of a revolving apparatus by alternately raising and lowering the flame. The first apparatus in which this method was employed was erected at Galley Head, Co. Cork (1878). At this lighthouse 4 of Wigham’s large gas burners with four tiers of first-order revolving lenses, eight in each tier, were adopted. By successive lowering and raising of the gas flame at the focus of each tier of lenses he produced the group-flashing distinction. The light showed, instead of one prolonged flash at intervals of one minute, as would be produced by the apparatus in the absence of a gas occulter, a group of short flashes varying in number between six and seven. The uncertainty, however, in the number of flashes contained in each group is found to be an objection to the arrangement. This device was adopted at other gas-illuminated stations in Ireland at subsequent dates. The quadriform apparatus and gas installation at Galley Head were superseded in 1907 by a first order biform apparatus with incandescent oil vapour burner showing five flashes every 20 seconds.

Flashing Lights indicating Numbers.—Captain F. A. Mahan, late engineer secretary to the United States Lighthouse Board, devised for that service a system of flashing lights to indicate certain numbers. The apparatus installed at Minot’s Ledge lighthouse near Boston Harbour, Massachusetts, has a flash indicating the number 143, thus: — — — —, the dashes indicating short flashes. Each group is separated by a longer period of darkness than that between successive members of a group. The flashes in a group indicating a figure are about 1½ seconds apart, the groups being 3 seconds apart, an interval of 10 seconds’ darkness occurring between each repetition. Thus the number is repeated every half minute. Two examples of this system were exhibited by the United States Lighthouse Board at the Chicago Exhibition in 1893, viz, the second-order apparatus just mentioned and a similar light of the first order for Cape Charles on the Virginian coast. The lenses are arranged in a somewhat

similar manner to an ordinary group-flashing light, the groups of lenses being placed on one side of the optic, while the other is provided with a catadioptric mirror. This system of numerical flashing for lighthouses has been frequently proposed in various forms, notably by Lord Kelvin. The installation of such a system in a horizontal position is not permissible, however, the first practical application of the system to large and important coast lights. The great cost involved in the alteration of the lights of any country to comply with the requirements of a numerical system of the type of the North American beacons, and the small divergence of the rays, visible only at or near the horizon, passing above the level of the eye. In practice this does not occur, sufficient natural divergence being produced ordinarily owing to the magnitude of the flame. In fixed dioptric lights there is, of course, no divergence in the horizontal plane. In flashing lights the horizontal divergence is a matter of considerable importance, determining as it does the duration or length of the flashes.

Fuselights or Quick Flashing Lights.—One of the most important developments in the character of lighthouse illuminating apparatus that has occurred in recent years has been in the direction of reducing the length of flash. The initiative in this matter was taken by the French engineer Dr. Garnier, who in 1847 first suggested the adoption of a system of quick flashing lights. The early fuselights, designed by the French engineers and others, had usually a flashing rate of 3 to 6 second duration. As a result of experiments carried out in France in 1903-1904, a flashing rate has been adopted for the British lighthouses of 7 seconds. The greater initial intensity of the flash permits this loss without serious detriment to effectiveness. Shorter flashes are used. It is found that the reduction in duration is attended by a corresponding, but not proportionate, diminution in effective intensity. In the case of many long focal lights the reduction in duration has been obtained only with the greater initial intensity of the flash permits this loss without serious detriment to effectiveness. Red or green requires a considerably greater duration than do white flashes. The intervals between the flashes in lights of this character are also small, 1/2 second to 7 seconds. In group-flashing lights the intervals between the flashes are about 2 seconds or even less, with periods of 7 to 10 or 15 seconds between the groups. The flashes are arranged in single, double, or multiple groups.

Fig. 40.—Skefford apparatus.

Fixed as far as the centre of the light as possible in order to reduce the escape of light rays due to divergence. These screens are usually attached to the lantern framing.

Flashing Lights.—The use of these, lights, which show a fixed beam varied at intervals by more powerful flashes, is not to be recommended, though a large number were constructed in the earlier years of dioptric illumination and many are still in existence. The apparatus can be provided in one of the following ways:—

(a) by the revolution of detached panels of straight condensing lens prisms placed vertically around a fixed light optic, (b) by utilizing revolving lens panels in the middle portion of the optic to produce the flashing light, the upper and lower portions consisting of being fixed zones of catadioptric or reflecting elements emitting a fixed belt of light, and (c) by interposing panels of fixed light section between the flashing light panels of a revolving apparatus. In certain cases the light is obtained by passing a fixed belt of light of low power to be entirely obscured while the flashes are visible, thus vitiating the true characteristic of the light. Cases have frequently occurred of such lights being mistaken for, and even described in lists of light as, revolving flashing lights.

"Cute" and Screens.—Screens of coloured glass, intended to distinguish the light in particular azimuths, and of sheet iron, when it is desired to 'cut off' the light sharply on any angle, should be

OPTICAL APPARATUS

Lighthouse

**Multiform Apparatus.**

In order to double the power to be obtained from a single apparatus at stations where lights of exceptionally high intensity are desired, the expedient of placing one complete lens apparatus above another has sometimes been adopted, as at the Bishop Rock (fig. 13), and at the Fastnet lighthouse in Ireland (Plate I., fig. 54). Triform and quadri-form apparatus have also been erected in Ireland; particulars of the Tory Island triform apparatus will be found in table VII.

The adoption of the multiform system involves the use of lanterns of increased height.

**Twin Apparatus.**

Another method of doubling the power of a light is by mounting two complete and distinct optics side by side on the same revolving table, as shown in fig. 43 of the Ile Vierge apparatus. Several such lights have been installed by the French Lighthouse Service.

**Port Lights.**

Small self-contained lanterns and lights are in common use for marking the entrances to harbours and in other similar positions where neither high power nor long range is requisite. Many such lights are unattended in the sense that they do not require the attention of a keeper for days and even weeks together. These are described in more detail in section 6 of this article. A typical port light consists of a copper or brass lantern containing a lens of the fourth order (250 mm. focal distance) or smaller, and a single wick or 2-wick Argand capillary burner. Duplex burners are also used. The apparatus may exhibit a fixed light or, more usually, an occulting characteristic is produced by the revolution of screens actuated by spring clockwork around the burner. The lantern may be placed at the top of a column, or suspended from the head of a mast. Coal gas and electricity are also used as illuminants for port lights when local supplies are available. The optical apparatus used in connexion with electric light is described below.

**"Orders" of Apparatus.**

Augustin Fresnel divided the dioptric lenses, designed by him, into "orders" or sizes depending on their local distance. This division is still used, although two additional "orders," known as "small third order" and "hyper-radial," respectively are in ordinary use. The following
table gives the principal dimensions of the several sizes in use:—

Lenses of small focal distance are also made for buoy and beacon lights.

Light Intensities.—The powers of lighthouse lights in the British Empire are expressed in terms of standard candles or in "lighthouse units" (one lighthouse unit = 1000 standard candles). In France the unit is the "Carcel" = 952 standard candle. The powers of burners and optical apparatus, then in use in the United Kingdom, were carefully determined by actual photometric measurement in 1892 by a committee consisting of the engineers of the three general lighthouse boards, and the values so obtained are used as the basis for calculating the intensities of all British lights. It was

found that the intensities determined by photometric measurement were considerably less than the values given by the theoretical calculations formerly employed. A deduction of 20% was made from the mean experimental values for loss by absorption in the lantern glass, variations in effects obtained by different men in working the burners and in the illuminating quality of oils, &c. The resulting reduced values are termed "service" intensities.

As has been explained above, the effect of a dioptic apparatus is to condense the light rays, and the measure of this condensation is the ratio between the vertical divergence and the vertical angle of the optic in the case of fixed lights. In flashing lights the ratio of vertical condensation must be multiplied by the ratio between the horizontal divergence and the horizontal angle of the panel. The loss of light by absorption in passing through the glass and by refraction varies from 10% to 15%. For apparatus containing catadioptric elements a larger deduction must be made.

The intensity of the flash emitted from a dioptic apparatus, showing a white light, may be found approximately by the empirical formula

\[ I = P \cdot C \cdot V \cdot H \cdot S \]

where:
- \( I \) = intensity of resultant beam
- \( P \) = service intensity of flame
- \( C \) = vertical angle of optic
- \( V \) = angle of mean vertical divergence
- \( H \) = horizontal angle of panel
of mean horizontal divergence, and 

\[ \text{mean horizontal divergence, and } C = \text{constant varying between } -9 \text{ and } -75 \] according to the description of apparatus. The factor 

\[ H/h \] must be eliminated in the case of fixed lights. Deduction must also be made in the case of coloured lights. It should, however, be pointed out that photometric measurements alone can be relied upon to give accurate values for lighthouse intensities. The values

The invention was quickly taken advantage of by lighthouse authorities, and the "Doty" burner, and other patterns involving the same principle, remained practically the only oil burners in lighthouse use until the last few years of the 19th century.

The lamps used for supplying oil to the burner are of two general types, viz., those in which the oil is maintained under pressure by mechanical action and constant level lamps. In the case of single wick, and some 2-wick burners, oil is supplied to the burner by the candle, action of the wick.

The mineral oils ordinarily in use are petroleum, which for lighthouse purposes should have a specific gravity of from 0.820 to 0.830 at 60 °F. and a boiling point of not less than 230 °F. (Abel close to the 0.820). Scottish ships carry paraffin with a specific gravity of about 0.810 at 60 °F. and flash point of 140° to 165 °F. Both these varieties may be obtained in England at a cost of about 6d. per gallon in bulk.

Coal Gas had been introduced in 1837 at the inner pier light of Troon (Ayrshire) and in 1847 it was in use at the Heugh lighthouse (West Hartlepool). In 1878 cannel coal gas was adopted for the Galley Head lighthouse, with 108-jet Wighan burners. Sir James Douglass introduced gas burners consisting of concentric rings, two to ten in numbers. These give excellent results and high intensity, 2000 candles in the case of the 10-ring burner with a flame diameter at the top of 53 in. They are still in use at certain stations. The use of multiple ring and jet gas burners is not being further extended. Gas for lighthouse purposes generally requires to be specially made; the extraction of gas works at the station is thus necessitated and a considerable outlay entailed which is avoided by the use of oil as an illuminant.

Incandescent Mineral Oil Burners.—Incandescent lighting with high-flash mineral oil was first introduced by the French Lighthouse Service in 1898 at L'Ile Penfret lighthouse. The burners employed are all made on the same principle, but differ slightly in details according to the type of lighting apparatus for which they are intended. The principle consists in injecting the liquid petroleum in the form of spray mixed with air into a vaporizer heated by the mantle flame or by a subsidiary heater. A small reservoir of compressed air is used, charged by means of a hand-pump for providing the necessary pressure for injection. On first ignition the ordinary jet burner is supplied with air to the oil at from 60 to 65 lb per sq. in. Small reservoirs containing liquefied carbon dioxide have also been employed for supplying the requisite pressure to the oil vessel.

The candle-power of apparatus in which ordinary petroleum wick burners were formerly employed is increased by several hundred per cent. per gallon. Oil, lard oil, and coconut oil have also been used for lighthouse purposes in various parts of the world.

Mineral Oil Burners.—The introduction of mineral oil, costing a mere fraction of the expensive animal and vegetable oils, revolutionized the illumination of lighthouses. It was not until 1868 that a burner was devised which successfully consumed hydro-carbon oils. This was a multiple wick burner invented by Captain Doty.

---

**Fig. 43A.**—The Vierge Apparatus and Lantern. Plan of focal plane, obtained by the use of Allard's formulae, which were largely used before the necessity for actual photometric measurements came to be appreciated, are considerably in excess of the true intensities.

**Fig. 44.**—"Chance" Incandescent Oil Burner, with 85 mm. diameter mantle. The vaporizers placed over the lighthouse. In other cases, of which the "Chance" burner (fig. 44) is a type, the vaporization is effected by means of a subsidiary burner placed under the main flame. The particulars of the sizes of burners in ordinary use are given in the following table.
The intrinsic brightness of incandescent burners generally may be taken as being equivalent to from 30 candles to 40 candles per sq. cm. of the vertical section of the incandescent mantle. The intrinsic brightness varies, according to the number of wicks and the type of burner from about 3.5 candles to about 12 candles per sq. cm., the value being at its maximum with the larger type of burner. The luminous intensity of a beam from a dolioporic apparatus is, \( c_\text{eris} \), proportional to the cube of the luminous intensity of the total luminous intensity. The intrinsic brightness of the flame of oil burners increases only slightly with their local diameter, consequently while the consumption of oil increases the efficiency of the burner, the apparent size of flame increases proportionally, so that the power of the condensed beam can only be improved to a slight extent, and, in fact, is occasionally decreased, by increasing the number of wicks in the burner. The same argument applies to the case of gas burners where multiple jets are used. Standing their large total intensity, have comparatively small intrinsic brightness. The economy of the new system is instanced by the case of the Eddystone bi-form apparatus, which with the concentric 6-wick burner consuming 2500 gals. of oil per annum, gave a total intensity of 79,250 candles. Under the new régime the intensity is 292,000 candles, the oil consumption being practically halved.

**Incandescent Oil Gas Burners.—**It has been mentioned that incandescence with low-pressure coal gas produces flames of comparatively small intrinsic brightness. Coal gas cannot be compressed beyond a small extent without considerable injurious condensation and other accompanying evils. Recourse has therefore been had to compressed oil gas, which is capable of undergoing compression to 10 or 12 atmospheres with little detriment, and can be condensed to a point in which it is used. The burners employed resemble the ordinary Bunsen burner with incandescent mantle, and the rate of consumption of gas is 27.5 cu. in. per hour per candle. A reducing valve is used for supplying the gas to the burner in any desired pressure, be left unattended for considerable periods. The system was first adopted in France, where it is installed at eight lighthouses, among others the Ar'men Rock light, and has been extended to other parts of the world including stations in Scotland and England. The burners used in France are of 35 mm. diameter. The 35 mm. mantle gives a candle-power of 400, with an intrinsic brightness of 20 candles per sq. cm.

The use of oil gas necessitates the erection of gas works at the lighthouse or its periodical supply in portable reservoirs from a neighbouring station. A complete gas works plant costs about $800. The annual expenditure for gas lighting in France does not exceed $72 per candle, whereas in the U. S. A. the gas supplied from elsewhere. In the case of petroleum vapour lighting the annual cost of oil amounting to about $26 per station.

**Acetylene.—**The high illuminating power and intrinsic brightness of acetylene renders it suitable for illuminating lighthouses and beacons, providing certain difficulties in its use can be overcome. At Grangemouth an unattended 21-day beacon has been illuminated by an acetylene flame for some years with entire satisfaction, and a beacon similar in principle and attended for six months was established on Bedloe Island in Loch Fyne, Australia in 1910. Acetylene has also been used in the United States, Germany, the Argentine, China, Canada, &c., for lighthouses and the British Islands. Many British and foreign beacons on the German and Dutch coasts have been supplied with oil gas mixed with 20% of acetylene, thereby obtaining an increase of over 100% in illuminating intensity. In France an incandescent burner consuming acetylene as a gas has been installed at one lighthouse (1902). The French Lighthouse Service has perfected an incandescent acetylene burner with a 55 mm. mantle having an intensity of over 2000 candle-power, with intrinsic brightness of 60 candles per sq. cm.

**Electricity.—**The first installation of electric light for lighthouse purposes in England took place in 1858 at the South Foreland, where the Trinity House established a temporary plant for experimental purposes, which was installed and illuminated in 1862 by the aid of the illuminating the Dungeness lighthouse. The remaining service in 1874 when oil was substituted for electricity. The earliest of the permanent installations now existing in France is that at Souter Point which was illuminated in 1871. There are in France four important coast lights illuminated by electricity, and one, viz. Isle of May, in Scotland. Of the former St Catherine’s, in the Isle of Wight, and the Lizard are the most powerful. Electricity substituted as an illuminant for the then existing oil and gas burners at St Catherine’s, whereby the latter was transferred to the South Foreland station in 1904, and a new second order (700 mm.) four-sided optic with a vertical angle of 130°, extending from 27th to 57th minute of arc, was installed for it. A fixed holophore is placed inside the optic in the dark or landward arc, and at the focal plane of the lamp. This holophore condenses the rays from the arc falling upon it into a pencil of light with an angular aperture of 4°. This pencil is directed horizontally by a series of reflecting prisms which again bend the light and throw it downwards through an aperture in the lantern floor to another series of prisms, which latter direct the rays seaward in the form of a sector of fixed red light at a lower level in the tower. A somewhat similar arrangement exists at Souter Point lighthouse.

The apparatus installed at the Lizard in 1893 is similar to that at St Catherine’s, but has no arrangement for producing a subsidiary sector light. The flash is of 13 seconds duration every 3 seconds. The apparatus replaced the two fixed electric lights erected in 1876. The Isle of May lighthouse, at the mouth of the Firth of Forth, was first illuminated by electricity in 1886. The optical apparatus consists of a second-order fixed-light lens with reflecting prisms, and is surrounded by a revolving system of vertical condensing prisms which split the vertically condensed beam of light into 8 separate beams of 3° in azimuth. The prisms are so arranged that the apparatus, making one complete revolution in the minute, produces a group characteristic of 4 flashes in quick succession every 30 seconds (fig. 45). The fixed light is not of the ordinary Fresnel

**Fig. 45.—Isle of May Apparatus.**
Planier had been lighted, in addition to the old apparatus at La Hève, it was decided to limit the installation of electrical apparatus to important lighthouse stations—a decision which the Trinity House had already made in the case of the English coast—and to establish new apparatus for the stations of Little, Penyennis, Great, and Cornubia. These were Crefch d'Ouessant (Ushant), Belle-Ile, La Coubre at the mouth of the river Gironde, Barfleur, Ile d'Yeu and Penmarc'h. At the same time it was determined to increase the powers of the existing electric lights. The scheme was for the following:

All the electrical light apparatus, in common with other apparatus established in France since 1893, have been provided with mercury-rotating. The most recent electric light apparatus have been constructed in the form of an apparatus, two complete and distinct Phare d'Yeu apparatus, mounted side by side upon the same revolving table and with corresponding faces parallel. It is found that a far larger aggregate candle-power is obtained from two lamps with 16 mm. to 23 mm. diameter, and that the luminosity of the lights is far better with smaller currents and larger dimensions in conjunction with single optics of greater focal distance. A somewhat similar circumstance led to the choice of the twin form for the two very powerful non-electric apparatus at Le Vierge (figs. 43 and 43A) and Audy, particularly of which will be seen in table VII.

Several of the de Meritans magneto-electric machines of 5.5 K.W., laid down many years ago at French electric light stations, are still in use. All these machines have five induction coils, which, upon the installation of the twin optics, were separated into two distinct circuits, each consisting of 24 coils. This modification has enabled the old plants to be used with success under the altered conditions. One apparatus of the de Meritans type, which was adopted in the French service for use at the later stations differ materially from the old type of de Meritans machine. The Phare d'Yeu apparatus is a type of the modern French builders, consisting of two dynamos supplied by the dynamos and two phase machines, and are installed in duplicate. The two lamps are supplied with current from the same machine, the second dynamo being held in reserve. The speed is 810 to 820 revolutions per minute.

The lamp generally adopted is a combination of the Serrin and Berjot principles, with certain modifications. Clockwork mechanism with a regulating electro-magnet moves the rods simultaneously and successively, the heads of the lamps being substituted by other heads at the same time as they are consumed. It is usual to employ currents of varying power with carbons of corresponding dimensions according to the atmospheric conditions. In the French service, an incandescent lamp is used for each station, with a current produced by currents of 60 and 120 amperes at 45 volts with carbons 14 mm. and 18 mm. diameter, while in single optic apparatus carbons of 25, 50 and 100 amperes are utilized with carbons of 11 mm., 16 mm. and 23 mm. diameter. In England fluted carbons of larger diameter are employed with correspondingly increased current. Alternating currents have given the most successful results in all respects. Attempts to utilize continuous current for lighthouse apparatus have generally proved unsuccessful.

The cost of a first-class electric lighthouse installation of the most recent type in France, including optical apparatus, lantanum, dynamos, engines, air compressor, siren, etc., but not buildings, amounts approximately 30,000 francs.

**Efficiency of the Electric Light.** In 1885 the lighthouse authorities of Great Britain determined that an exhaustive series of experiments should be carried out at the South Foreland with a view to ascertain ing the relative advantage of oil as an illuminant and gas as a illuminant. The experiments extended over a period of more than twelve months, and were attended by representatives of the chief lighthouse authorities of the world. The results of the trials tended to show that the cost of oil and gas lights was about equal, or lower, by gas, the advantage over, by gas, by reason of its greater economy in cost of maintenance and in initial outlay on installation. The electric light was found to suffer from the frequent necessity of replacement of the filament, and the power required for unit oil or gas light was much less by atmospheric absorption, but the infinitely greater total intensity of the beam obtainable by its use, both by reason of the high luminous intensity of the electric arc and its focal compactness, more than compensated for this disadvantage. The final conclusion of the committee on the relative merits of electricity, gas or oil as lighthouse illuminants is given in the following words:

"That for ordinary necessities of lighthouse illumination, mineral oil is preferable to gas and gas preferable to electricity, except in headlands, important landfalls, and places where a very powerful light is required electricity offers the greater advantages."

**S. MISCELLANEOUS LIGHTHOUSE EQUIPMENT.**

**Towers.—**Modern lighthouse towers are generally of steel and circular in plan, on which is erected the lantern glass, sur mounted by a domed roof and ventilator (fig. 41). Adequate ventilation is of great importance, and is provided by means of ventilators in the pedestal and a large ventilating dome or cow in the roof. The astragals carrying the glazing are of wrought steel and cast-iron, the latter being cast in two parts, one being of the ventilator or radial, and the other of the astroglas or radial, forming a continuous piece of glass. Thus, a minimum of obstruction to the light rays is obtained in any vertical or horizontal section. The greater rigidity of the structure is thereby increased. Lantern roofs are of sheet steel or copper secured to steel or cast-iron rafter frames. In certain instances it is found necessary to erect a grile or network outside the lantern to prevent the numerous birds, which fly into the lights, from breaking the glazing by impact. Lanterns vary in diameter from 5 ft. to 16 ft., or more, according to the size of the optical apparatus.

**Lighthouses Containing Electric Night Lamps.** Important structures in a lighthouse are usually connected to the lightning conductor carried either to a point below low water or terminating in an earth plate embedded in wet ground. Conductors may be of copper tape or copper-wire rope.

**Rotating Machinery.**—Flashing-light apparatus are rotated by a clockwork mechanism actuated by weights. The clock are fitted with speed governors and electric warning apparatus to indicate variation in speed and when rewinding is required. For occulting apparatus either weight clocks or spring clocks are employed.

**Accommodation for Keepers, &c.**—At rock and other isolated stations, accommodation for the keepers is usually provided in the form of a small building, the occupants of which dwellings are provided in close proximity to the tower. The service or watch room should be situated immediately under the lantern floor. Oil is usually stored in galvanized steel tanks. A force pump is sometimes used for providing a supply of water to the storage tanks to a service tank in the watch-room or lantern.

**6. UNATTENDED LIGHTS AND BEACONS.**—Until recent years no unattended lights were in existence. The introduction of Pintsch's electric lighthouse has greatly increased the possibilities of a means of illumination for beacons and buoys of which large use has been made. Other illuminants are also in use to a considerable extent.

**Unattended Electric Lighthouse.**—In 1884 an iron beacon lighted by an independent dynamo with oil from a secondary battery was erected on a tidal rock near Càdiz. A 24-day clock was arranged for eclipsing the light between sunrise and sunset and automatically cutting off the current at intervals to produce an occulting effect. Several of the twin electric lamps have been made by the firm of Barbier Bénard et Turenne of Paris, and supplied with current from batteries of Daniell cells, with electric clockwork mechanism for occulting the light. These apparatus have been fitted to beacons and buoys, and are generally arranged to automatically switch off the current during the daytime. They run unattended for periods up to two months. Two separate lenses and lamps are usually provided, with a flash producing the effect of failure in the upper lamp of the two the current automatically passes to the lower lamp.

**Oil-gas Beacons.**—In 1881 a beacon automatically lighted by Pintsch's compressed gas was erected on the river Clyde, and large numbers of these structures have since been installed in all parts of the world. The gas is contained in an iron or steel reservoir placed within the beacon structure, refilled by means of a flexible hose on the occasion of the periodical visits of the tender. The beacon, when first illuminated, is refilled from the tender in the event of failure of the upper lamp of the two the current automatically passes to the lower lamp.

**B. MISCELLANEOUS LIGHTHOUSE EQUIPMENT.**

**Lighthouses.—**In 1881-1882 several lighthouses lighted automatically by volatile petroleum spirit on the Lindberg-Lyth and Lindberg-Trotter systems were established in Sweden. The latter type have subsequently been placed in different parts of the world. The volatile spirit lamp burns day and night. Occulta
tion is produced by a screen or series of screens rotated round the light by the ascending current of heated air and gases from the lamp.
acting upon a horizontal fan. The speed of rotation of the fan cannot be accurately adjusted, and the times of occultation therefore are liable to slight variation. The lights run unattended for periods up to twenty-one days.

**Benzon-Lee Lamps.** An improvement upon the foregoing is the Benzon-Lee lamp, in which a similar occulting arrangement is often used, but the illuminant is paraffin consumed in a special burner having carbon-tipped wicks which require no trimming. The flame intensity is adjusted by varying the size of the wick, and the light is self-regulating. The introduction of paraffin also avoids the danger attending the use of the more volatile spirit. Many of these lights are in use on the Scottish coast. They are also used in other parts of the United Kingdom, and in the United States, Canada and other countries.

**Permanent Wick Lights.**—About 1891 the French Lighthouse Service introduced petroleum lamps consuming ordinary high-flash lighthouse oil, and burning without attention for periods of several months. A system of special construction, provided with a very thick wick which is in the first instance treated in such a manner as to cause the formation of a deposit of carbonized tar on its exposed upper surface. This crust prevents further charring of the wick after ignition, the oil becomingemporized as it passes. The rotation is effected by means of a small Gramme motor on a vertical axis, fitted with a speed governor, and supplied with current from a battery of primary cells. The oil reservoir is placed in the upper part of the lantern, in which there is a tube in which the wicks are formed. The rotation is caused by the current passing through the wicks, which are provided with a constant level regulator for maintaining the burning level of the oil at a fixed height. In the flashing or revolving light types the arrangement is generally similar, the lenses being revolved upon a horizontal axis by means of a motor. The light is furnished by an apparatus established at St Marcouf in 1901 has a beam intensity of 1,000 candle-power, and is capable of running unattended for three months. The electric current employed for rotating the apparatus is supplied by four Lalande and Chaperon primary cells, couplings each of which giving about 0·15 ampere at a voltage of 0·65. The power required to work the apparatus is at the maximum about 0·165 ampere at 0·75 volt, the large surplus of power which is provided for the sake of safety being absorbed by a brake or governor at the expense of the motor efficiency.

**Wigham Beacon Lamps.**—Wigham introduced an oil lamp for beacon and buoy purposes consisting of a vertical container filled with ordinary mineral oil or paraffin, and carrying a roller immediately behind which a wick is passed, giving about 0·15 ampere at a voltage of 0·65. The roller is turned by being driven between the convex surface of the wick as it passes over the roller, a portion of the wick being constantly passed under the action of the flame. The light is capable of burning without attention for thirty days. The light is used in regions where it is considered better to use gas or other means of illumination than the Lindberg system. The candle-power of the flame is small.

### 7. LIGHT-VESSELS

**7. Light-Vessels.**—The earliest light-vehicle placed in English waters was that at the Nore in 1732. Such early vessels were of small size and carried light in lanterns, which was suspended from the yard-arms. Modern light-vessels are of steel, wood or composite construction. Steel is now generally employed in new ships. The wood and composite ships are sheathed with steel or metal and designed for station-light vehicles vary. The following may be taken as the usual limits:

<table>
<thead>
<tr>
<th>Length</th>
<th>Beam</th>

<tbody>
<tr>
<td>80 ft. to 114 ft.</td>
<td>20 ft. to 24 ft.</td>
<td>13.5 ft. to 6 in.</td>
</tr>
<tr>
<td>155 to 280.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The larger vessels are employed at outside and exposed stations, the smaller ships being stationed in sheltered positions and in estuaries.

The moorings usually consist of 3-ton mushroom anchors and 11·5 ft. plate chain. The webbing or chain is about 2·5 ft. off the bottom, circular in form, with glazing 4 ft. in height. They are anular in plan, surrounding the mast of the vessel upon which they are hoisted for illumination, and are lowered to the deck level during the day. The vessel is also equipped with a small wooden motor, which is sometimes used and sometimes not. The oil burners are being used in many services, and are gradually replacing the older type. The first English light-vehicle so equipped was constructed in 1894. Of the 87 light-vessels in British waters, including unattended light-vessels, eleven are in Ireland and six in Scotland. At the present time there are over 750 light-vessels in service throughout the world.

Until about 1893 the illuminating apparatus used in light-vessels was of the horizontal form, consisting of three silvered parabolic reflectors, having 1, 2 or 3-wick mineral oil burners in focus. The reflectors and lamps are hung in gimbals to preserve the horizontal direction of the beams.

The following table gives the intensity of beam obtained by means of a type of reflector in general use:

<table>

</tr>
</tbody>
</table>

In revolving flashing lights or more reflectors are arranged in parallel in each face. Three, four or more faces or groups of reflectors are arranged around the lantern in which they revolve, and are driven by the turn or rotation of the lantern. The intensity of the flashing beam is therefore equivalent to the combined intensities of the beams emitted by the several reflectors in each face. The first light-vessel with revolving light was placed at the Swin Middle at the Marshal lighthouse, the 3-wick apparatus consisting of the characteristics can be produced by special arrangements of the reflectors. Dioropic apparatus is now being introduced in many new vessels, the first to be so fitted in England being that stationed at the Swin Middle in a vessel which is gas illuminated and gives a flash of 25,000 candle-power.

Fog signals, when provided on board light-vessels are generally in the form of reed-horns or sirens, worked by compressed air. The compressors and apparatus are driven from steam or other engines.

**Electrical Illumination.**—An experimental installation of the electric light placed on board a Mersey light-vessel in 1886 by the Mersey Docks and Harbour Board proved unsuccessful. The United States Lighthouse Board in 1892 constructed a light-vessel provided with a powerful electric light, and moored her on the coast of Maine. The vessel was afterwards replaced by Sandy Hook (1894) and transferred to the Ambrose Channel Station in 1907. Five other light-vessels in the United States have since been provided with incandescent electric lamps.

**Gas Illumination.**—In 1896 the French Lighthouse Service commenced to use steel light-vessel (Talais), which was ultimately placed at the mouth of the Guine.

The construction of this vessel was the result of experiments carried out with a view to produce an efficient light-vessel at moderate cost by a system of gas illumination. The construction of the Talais was followed by that of a second and larger vessel, the Snouw, on similar lines, having a length of 65 ft. 6 in., beam 20 ft. and a draught of 12 ft., with a displacement of 130 tons. The cost of this vessel complete with optical apparatus and gas holders, with accessories, has been estimated at £500. The vessel was built in 1889-1890.

A third vessel was constructed in 1901-1902 for the Sandetté Bank on the general lines adopted for the preceding examples of her class, but of the following increased dimensions: length 115 ft.; width at water-line 20 ft. 6 in. and draught 15 ft., with a displacement of 342 tons (fig. 47). Accommodation is provided for a crew of eight men. The optical apparatus (fig. 48) is dioptric, consisting of three canons of 250 mm. focal distance, carried upon a framework of metal, and mounted on a lattice, the engine being driven by steam and an oil siren.

**Unattended Light-Vessels.**—In 1881 an unattended light-vessel, illuminated with Pintsch's oil gas, was constructed for the Clyde, and is still in use at the Garvel Point. The light is occulting, and is supplied with one dioptric apparatus, with oil burners placed in a 50-ft. tower 30 ft. above water-level. The vessel is of iron, 40 ft. long, 12 ft. beam and 8 ft. deep, and has a holder on board containing oil gas under a pressure of six atmospheres capable of maintaining a light for three months. A similar vessel is placed off Calshot Spit in Southampton Water, and several have been constructed for the

---

*Both the Talais and Snouw light-vessels have since been converted into unattended light vessels.*
French and other Lighthouse Services. The French boats are provided with deep main and bilge keels similar to those adopted in the larger gas illuminated vessels. In 1901 a light-vessel 50 ft. in length was placed off the Otter Rock on the west coast of Scotland; side of the rock. The conductor terminated in a large copper plate, and to the cable end was attached a copper mushroom. Weak currents were induced in the lighthouse conductor by the main current in the cable, and messages received in the tower by the help of electrical relays. On the completion of the new tower on the Fastnet Rock in 1906 this installation was superseded by a wireless telegraphic installation.

8. DISTRIBUTION AND DISTINCTION OF LIGHTS, &c.—Methods of Distinction.—The following are the various light characteristics which may be exhibited by the mariners:

Fixed.—Shining a continuous or steady light. Seldom used in modern lighthouses and generally restricted to small port or harbour lights. A fixed light is liable to be confused with lights of shipping or other shore lights.

Flashing.—Showing a single flash, the duration of darkness always being greater than that of light. This characteristic or that immediately following is generally adopted for important lights. The French authorities have given the name Feux-Eclair to flashing lights of short duration.

Group-Flashing.—Showing groups of two or more flashes in quick succession (not necessarily of the same colour) separated by eclipses with a larger interval of darkness between the groups.

Fixed and Flashing.—Fixed light varied by a single white or coloured flash, which may be preceded and followed by a short eclipse. This type of light, in consequence of the unequal intensities of the beams, is unreliable, and examples are now seldom installed although many are still in service.

Fixed and Group-Flashing.—Similar to the preceding and open to the same objections.

Revolving.—This term is still retained in the “Lists of Lights” issued by the Admiralty and some other authorities to denote a light gradually increasing to full effect, then decreasing to eclipse. At short distances and in clear weather a faint continuous light may be observed. There is no essential difference between revolving and flashing lights, the distinction being merely due to the speed of rotation, and the term might well be abandoned as in the United States lighthouse list.

Occulting.—A continuous light with, at regular intervals, one sudden and total eclipse, the duration of light always being equal to or greater than that of darkness. This characteristic is usually exhibited by fixed dioptric apparatus fitted with some form of occulting mechanism. Many lights formerly of fixed characteristic have been converted to occulting.

For the purposes of the mariner a light is classed as flashing or occulting solely according to the duration of light and darkness and without any reference to the apparatus employed. Thus, an occulting light is classed in the Admiralty “List of Lights” as a “flashing” light.
Group Occulting.—A continuous light with, at regular intervals, groups of two or more sudden and total eclipses.

Alternating.—Lights of different colours (generally red and white) alternately without any intervening eclipse. This characteristic is not to be recommended for reasons which have already been referred to. Many of the permanent and unwatched lights on the coasts of Norway and Sweden are of this description.

Colour.—The colours usually adopted for lights are white, red and green. White is to be preferred whenever possible, owing to the great absorption of light by the use of red or green glass screens.

Sectors.—Coloured lights are often requisite to distinguish cuts or sectors, and should be shown from fixed or occulting light apparatus and not from flashing apparatus. In marking the passage through a channel, or between sandbanks or other dangers, coloured light sectors are arranged to cover the dangers, white light being shown over the fairway with sufficient margin of safety between the edges of the coloured sectors next the fairway and the dangers.

Choice of Characteristic and Description of Apparatus.—In determining the choice of characteristic for a light due regard must be paid to existing lights in the vicinity. No light should be placed on a coast line having a characteristic the same as, or similar to, another in its neighbourhood unless one or more lights of dissimilar characteristic, and at least as high power and range, intervene. In the case of "landfall lights" the characteristic should differ from any other within a range of 100 m. In narrow seas the distance between lights of similar characteristic may be less. Landfall lights are, in a sense, the most important of all and the most powerful apparatus available should be installed at such stations. The distinctive characteristic of a light should be such that it may be readily determined by a mariner without the necessity of accurately timing the period or duration of flashes. For landfall and other important coast stations flashing dioptric apparatus of the first order (920 mm. focal distance) with powerful burners are required. In countries where the atmosphere is generally clear and fogs are less prevalent than on the coasts of the United Kingdom, second or third order lights suffice for landfalls having regard to the high intensities available by the use of improved illuminating devices. Secondary coast lights may be of second, third or fourth order of flashing character, and important harbour lights of third or fourth order. Less important harbours and places where considerable range is not required, as in estuaries and narrow seas, may be lighted by flashing lights of forth order or less. Where sectors are requisite, occulting apparatus should be adopted for the main light; or subsidiary lights, fixed or occulting, may be exhibited from the same tower as the main light but at a lower level. In such cases the vertical distance between the main and subsidiary lights must be sufficient to avoid commingling of the two beams at any range at which both lights are visible. Such commingling or blending is due to atmospheric aberration.

Range of Visibility.—The range of a light depends first on its elevation above sea-level and secondly on its intensity. Most important lights are of sufficient power to render them visible at the full geographical range in clear weather. On the other hand there are many harbour and other lights which do not meet this condition.

The distances given in lists of lights from which lights are visible—except in the cases of lights of low power for the reasons above—are usually calculated in nautical miles as seen from a height of 15 ft. above sea-level, the elevation of the lights being taken as above high water. Under certain atmospheric conditions, and especially with the more powerful lights, the glare of the light may be visible considerably beyond the calculated range.

Table III.—Distances at which Objects can be seen at Sea, according to their Respective Elevation and the Elevation of the Eye of the Observer. (A. Stevenson.)

Example: A tower 200 ft. high will be visible 20-66 nautical miles to an observer, whose eye is elevated 15 ft. above the water; thus, from the table:

15 ft. elevation, distance visible 4:44 nautical miles

Elevation of Lights.—The elevation of the light above sea-level need not, in the case of landfall lights, exceed 200 ft., which is sufficient to give a range of over 20 nautical miles. One hundred and fifty feet is usually sufficient for coast lights. Lights placed on high headlands are liable to be enveloped in banks of fog at times when at smaller size. When the atmosphere is comparatively clear (e.g. Beachy Head). No definite rule can, however, be laid down, and local circumstances, such as configuration of the coast line, must be taken into consideration in every case.

Choice of Characteristic.—Landfall stations should receive first consideration and the choice of location for such a light ought never to be made subservient to the lighting of the approaches to a port. Subsidiary lights are available for the latter purpose. Lights installed to guard shoals, reefs or other dangers should, when practicable, be placed seaward of the danger itself, as it is desirable that seamen should be able to "make" the light with confidence. Sectors marking dangers
seaward of the light should not be employed except when the danger is in the near vicinity of the light. Outlying dangers require marking by a light placed on the danger or by a floating light in its vicinity.

9. ILLUMINATED BUOYS.—Gas Buos. Pintcho's gas oil has been in use for the illumination of buoys since 1875. In 1883 an automatic occulter was perfected, worked by the gas passing from the reservoir to the burner. The lights placed on these buoys burn continuously for three or more months. The buoys and lanterns are made in various forms and sizes. The spar buoy (fig. 50) may be adopted for situations where strong tides or currents prevail. Oil gas lights are frequently fitted to Courtenay whistling (fig. 51) and bell buoys.

In the ordinary type of gas buoy the lantern the burner employed is of the multiple-jet, Argand, or incandescent type. Incandescent mantles have been applied to buoy light in France with successful results. Since 1906, and more recently the same system of illumination has been adopted in England and other countries. The lenses employed are of cylindrical dioptric fixed-light form, usually 100 mm. to 300 mm. diameter. Some of the largest types of gas-buoy in use on the French coast have an elevation from water level to the focal plane of over 26 ft. with a beam intensity of more than 1000 candles. A large gas-buoy with an elevation of 34 ft. to the focal plane was placed at the entrance to the Gironde in 1907. It has an incandescent burner and exhibits a light of over 1500 candles. Oil gas forms the most trustworthy and efficient illuminant for buoy purposes yet introduced, and the system has been largely adopted by lighthouse and harbour authorities.

There are now over 2000 buoys fitted with oil gas apparatus, in addition to 600 beacons, light-vessels and boats.

Electric Lit Buoys.—Buoyes have been fitted with electric light, both fixed and occulting. Six electrically lit spar-buoys were laid down in the Gedney channel, New York lower bay, in 1888. These were illuminated by 100 candle-power Swan lamps with continuous currents supplied by cable from a power station on shore. The wear and tear of the cables caused considerable trouble and expense. In 1895 alternating current was introduced. The installation was superseded by electric buoys in 1904.

Acetylene and Oil Lit Buoys.—Acetylene has been extensively employed for the lighting of buoys in Canada and in the United States; to a less extent it has also been adopted in other countries. Both the low pressure system, by which the acetylene gas is produced by an automatic generator, and the so-called high pressure system in which purified acetylene is held in solution in a high pressure gasholder filled with asbestos composition saturated with acetone, have been employed for illuminating buoys and beacons. Wigham oil lamps are also used to a limited extent for buoy lighting.

Bell Buos.—One form of clapper actuated by the roll of the buoy shown in fig. 52 consists of a harden steel ball placed in a horizontal phosphor-bronze cylinder provided with rubber buffers. Three of these cylinders are arranged around the mouth of the fixed bell, which is struck by the balls rolling backwards and forwards as the buoy moves. Another form of bell is a fixed bell with three or more placed externally which strike the bell when the buoy rolls.

Fog Signals.—The introduction of coast fog signals is of comparatively recent date. They were, until the middle of the 19th century, practically unknown except so far as a few isolated bells and guns were concerned. The increasing demands of navigation, and the application of steam power to the propulsion of ships resulting in a decrease of their speed, drew attention to the necessity of providing suitable signals as aids to navigation during fog and mist. In times of fog the mariner can expect no certain assistance from even the most efficient system of coast lighting, since the beams of light from the most powerful electric lighthouse are frequently entirely dispersed and absorbed by the particles of moisture, forming a sea fog of even moderate density, at a distance of less than a mile from the shore. The careful experiments and scientific research which have been devoted to the subject of coast fog-signal making have produced much that is useful and valuable to the mariner, but unfortunately the practical results so far have not been so satisfactory as might be desired, owing to (1) the very short range of the most powerful signals yet produced; (2) the difficulty experienced by the mariner in judging at any point the strength of the atmospheric conditions and (3) the difficulty in locating the position of a sound signal by phonographic observations.

Under certain unfavourable acoustic conditions of the atmosphere, (2) and (3) are the greatest difficulties experienced by the mariner. In judging at any point the strength of the atmospheric conditions and (3) the difficulty in locating the position of a sound signal by phonographic observations.

Fig. 51.—Courtenay's Automatic Whistling Buoy.

Fig. 52.—Buoy Bell.

of 14 m. across a gentle breeze and at over 9 m. against a 10-knot breeze. Bells are frequently used for beacon and buoy signals, and in some cases at isolated rock and other stations where there is insufficient accommodation for sirens and horns, but their use is being gradually discontinued in this country for situations where a
FOG SIGNALS]

Lighthouse

A powerful signal is required. Gongs, usually of Chinese manufacture, were formerly in use on board English lightships and are still used to some extent abroad. These are being superseded by more powerful sound instruments.

Extraction of Light-vessels.—Guns were long used at many lighthouse and light-vessel stations in England, and are still in use in Ireland and at some foreign stations. These are being gradually displaced by other explosive or compressed air signals. No explosive signals are in use in the coasts of the United States. In 1878 sound rockets charged either with gun-cotton or with nitroglycerin were first used at Flamborough Head and were afterwards supplied to many other stations. The nitroglycerin or tonite signals in general use are made up in oz. charges. These are hung at the end of an iron jib or pole attached to the lantern of the lighthouse or other structure, and fired by means of a detonator and electric battery. The discharge may take place within 12 ft. of a structure without danger. The cartridges are stored for a considerable period without deterioration and with safety. Charging is easy, and the charge is fired without the least explosion of the charge or of the charge when the cartridge is exploded. The signal is produced by the report of the explosion, which is heard at a distance of several miles, and is accompanied by a red flash when the explosive is nitroglycerin. The nitroglycerin or tonite signal is a great improvement over the older form of signal, and is much used in the United States, Great Britain, Canada, Newfoundland, and other parts of the world. The signal is produced by the explosion of a charge of nitroglycerin or tonite in a metal pipe. The charge is ignited by an electric current or by a detonator. The signal is heard at a distance of several miles and is accompanied by a red flash when the explosive is nitroglycerin.

Whistles.—Whistles, whether sounded by air or steam, are not used in Great Britain, except in two instances of harbour signals under local control. Air whistles have been adopted at Flamborough Head and have a resemblance to steamer’s whistles, and the use of steam whistles is increasing.
were also made with different pattern of trumpets, including forms having elliptical sections, the long axis being placed vertically. The conclusions of the committee may be briefly summarized as follows: (1) When a large arc is required to be guarded two fixed trumpets may be used, one on each side of the arc, capable of being rotated. (2) When the arc to be guarded is larger than that effectively covered by two trumpets, the mushroom-head trumpet is a satisfactory instrument for the purpose. (3) A siren rotated slowly may yield better results than when self-driven. (4) No advantage commensurate with the additional power required is obtained by the use of air at a higher pressure than 25 lb per sq. in. (5) The number of vibrations per second produced by the siren or reed should be in unison with the proper note of the associated trumpet. (6) When two notes of different pitch are employed the difference between these should, if possible, be an octave. (7) For calm weather a low note is more suitable than a high note, and would be more frequently heard than a trumpet. (8) From causes which cannot be determined at the time or previous to the presence, areas sometimes exist in which the sounds of fog signals may be greatly enfeebled or even lost altogether. This effect was more frequently observed during comparatively calm weather and at no great distance from the signal station. (9) The siren was the most effective signal experimented with; the reed-horn, although inferior in power, is suitable for situations of secondary importance. (10) Other signals, such as the fog, if used with a siren, the signals must be regarded only as an auxiliary aid to navigation, and cannot at all times be relied upon.

Submarine Bell Signals.—As early as 1841 J. D. Colladon conducted experiments on the lake of Geneva to test the suitability of water as a medium for transmission of sound signals and was able to convey distinctly audible sounds through water for a distance of over 21 m., but it was not until 1904 that any successful practical application of sound transmission by means of water-bells was made. The results were obtained by placing the bell some distance from the shore in water, and reducing the water to the bell. In some cases, when submarine bells are associated with gas buoys or buoys, the compressed gas is employed to actuate the bell striking mechanism. To take full advantage of the signals thus provided it is necessary to approach the signals by means of a water-bell receiver, acting as a hydrostatic element to conduct the water wave line in contact with the water plating. The water is then a medium for ordinary telephonic transmission, and the direction of the bell in reference to the moving ship can be determined within narrow limits. The system is likely to be widely extended, and many merchant vessels and war ships have been fitted with signal receiving apparatus.

The following table (V.) gives the total numbers of fog signals of each class in use on the 1st of January 1910 in certain countries.

Some small harbour and river lights of subsidiary character are not included in the above total.

United States.—The United States Lighthouse Board was constituted by act of Congress in 1852. The Secretary of Commerce and Labor is the ex-officio president. The board consists of two officers of the navy, two engineer officers of the army, and two civilian engineer-in-chiefs of the board. The board is divided into 16 districts for purposes of administration.

11. Lighthouse Administration. The principal countries of the world possess organized and central authorities responsible for the installation and maintenance of coast lights and fog signals, buoys and beacons.

**United Kingdom.** In England the corporation of Trinity House, or according to its original charter, “The Master Wardens, and Assistants of the Guild Fraternity or Brotherhood of the most glorious and undivided Trinity and of St. Clement, in the Parish of Deptford Strand, in the county of Kent,” existed in the reign of Henry VII. As a religious house it was connected with the shipmasters, and was incorporated during the reign of Henry VIII. In 1565 it was given certain rights to maintain beacons, &c., but not until 1680 did it own any lighthouses. Since that date it has gradually purchased most of the privately-owned lighthouses and has erected many new ones. The act of 1836 gave the corporation control of English coast lights with certain supervisory powers over the numerous local lighting authorities, including the Irish and Scottish boards. The corporation now consists of a Master, Deputy-master, and 22 other brethren. The corporation controls the Commissioners of Northern Lighthouses constituted in 1786 and incorporated in 1798. The lighting of the Irish coast is in the hands of the Commissioners of Irish Lights formed in 1867 in succession to the old Dublin Ballast Board. The principal local lighthouses in the United Kingdom are the Mersey Docks and Harbour Board, and the Clyde Lighthouse Trustees. The three general lighthouse boards of the United Kingdom, by the provision of the Mercantile Marine Act of 1854, are subordinate to the Board of Trade, which controls all finances.

On the 1st of January 1910 the lights, fog signals and submarine bells in service under the control of the several authorities in the United Kingdom were as follows:

When two kinds of signal are employed at any one station, one being subsidiary, the latter is omitted from the enumeration. Buoy and unattended beacon bells and whale oil buoys are not included in the present list. The various lighthouse boards are included, more especially in Great Britain.

France.—The lighthouse board of France is known as the Commission des Phares, dating from 1792, and remodelled in 1811, and is under the direction of the minister of public works. It consists of six engineers, two naval officers and one member of the Institute, one inspector-general of marine engineers, and one hydrographic engineer. The chief executive officers are an Inspecteur Général des Ponts et Chaussées, who is director of the board, and another engineer of the same corps, who is engineer-in-chief and secretary. The board has control of about 750 lights, including those of

1. The dates given are of the establishment of the optical apparatus. In many cases incandescent burners have been installed at later dates.
LIGHTING

Corse, Algeria, &c. A similar system has been established in Spain.

English Colonies.—In Canada the coast lighting is in the hands of the minister of marine, and in most other colonies the public works departments have control of lighthouse latters. In Denmark, Norway, and many other countries the minister of marine has charge of the lighting and buoying of coasts; in Belgium the public works department controls the service.

In general, services at shore lighthouse stations there are usually two keepers, at rock stations three or four, one being ashore on leave. When there is a fog signal at a station there is usually an additional keeper, and at electric light stations a mechanical engineer is almost always added to the existing personnel. The crew of a lighthouse is a rule consist of 11 men, three of them and the master or mate going on shore in rotation.

The average annual cost of maintenance of an English shore lighthouse is £7,600. For shore lighthouses with three keepers and a siren fog signal the average cost is £444. The maintenance of a rock lighthouse with four keepers and an explosive fog signal is about £750, and an electric light station costs about £1,100.

A light-vessel of the ordinary type in use in the United Kingdom entails an annual expenditure on maintenance of approximately £1,200, excluding the cost of periodical overhaul.

1. OIL LIGHTING

From the earliest times the burning of oil has been a source of light, but until the middle of the 19th century only oils of vegetable and animal origin were employed in indoor lamps for this purpose. Although many kinds were used locally, only colza and sperm oils had any very extended use, and they have been practically supplanted by mineral oil, which was introduced as an illuminant in 1853.

Up to the latter half of the 18th century the lamps were shallow vessels into which a short length of wick dipped; the flame was smoky and discharged acrid vapours, giving the minimum of light with the maximum of smell. The first notable improvement was made by Ami Argand in 1784. His burner consisted of two concentric tubes between which the tubular wick was placed; the open inner tube led a current of air to play upon the inner surface of the circular flame, whilst the combustion was materially improved by placing around the flame a chimney which rested on a perforated gallery a short distance below the burner. Argand's original burner is the parent form of innumerable modifications, all more or less complex, such as the Carcel and the moderator.

A typical example of the Argand burner and chimney is represented in fig. 1, in which the burner is composed of three tubes, d, f, g. The tube g is soldered to the bottom of the tube d just above c, and the interval between the outer surface of the tube g and the inner surface of the tube d is an annular cylindrical cavity closed at the bottom, containing the cylindrical cotton wick immersed in oil. The wick is fixed to the wick tube a, which is capable
of being moved spirally; within the annular cavity is also the tube \( f \), which can be moved round, and serves to elevate and depress the wick. \( P \) is a cap that screws on the bottom of the tube \( d \), and receives the superfluous oil that drops down from the wick along the inner surface of the chimney \( g \). The wick passes through the holes \( a, o, \), and passes up through the tube \( g \) to maintain the combustion in the interior of the chimney \( g \). The air which maintains the combustion on the exterior part of the wick enters through the holes \( m \), with which \( m \) is perforated. When there is no chimney, or the chimney is rarefied by the heat of the flame, the surrounding heavier air, entering the lower part of the chimney, passes upward with a consequent current, to reestablish the equilibrium. \( R G \) is the cylindrical glass chimney with a shoulder or constriction at \( R, G \). The oil flows through the air space between the tubes \( g \) and \( d \). The part \( k \) is a short tube, which receives the circular wick, and slides spirally on the tube \( g \), by means of a pin working in the spiral groove on the exterior surface of \( g \). The wick-tube has also a catch, which works in a perpendic-ular slit in the tube \( f \); and, by turning the wick, the wick-tube \( g \) be raised or lowered, for which purpose a ring, or gallery, \( m \), fits on the tube \( d \), and receives the glass chimney \( G \); a wire \( S \) is attached to the tube \( G \), and bending over, descends along the outside of \( d \). The part \( r \), that supports the glass chimney, is connected by four other wires, one \( S \), which surrounds the tube \( d \), and can be moved round. When \( r \) is turned round, it carries with it the ring \( q \), the spring \( E \), and the tube \( f \), thus raising and lowering the wick. A device in a form of a small metallic disk or button, known as the Liverpool button from having been first adopted in the so-called Liverpool lamp, effects for the current of air passing up the interior of the Argand burner the same prevention of the escape of oil as the reservoir \( G \) provides in the case of the external tube. The button \( B \), fixed on the end of a wire is placed right above the burner tube \( g \), and allows equally all round through the passage of the flame the current of air which passes up through \( g \). The result of these expedients, when properly applied, is the production of an exceedingly solid, brilliant white light, absolutely smokeless, this showing that the combustion of the oil is perfectly accomplished.

The means by which a uniformly regulated supply of oil is brought to the burner varies with the position of the reservoir. In some lamps, not now in use, by ring-formed reservoirs and other expedients, the whole of the oil was kept as nearly as possible at the level of the burner. In what are termed fountain reading, or study lamps, the principal reservoir is above the burner level, and various methods adopted for securing a supply from them at the level of the burner. But the most convenient position for the reservoir in lamps for general use is directly under the burner, and in this case the stand of the lamp itself is utilized as the oil vessel. In the long time, and vegetable oils, as the oils of animal and vegetable origin used to be called, it is necessary with such lamps to introduce some appliance for regulating a supply of oil to the burner, and many methods of effecting this were devised, most of which were ultimately superseded by the so-called Argand burner. The so-called reading lamp, invented by B. G. Carcel in 1800, is still to some extent used in France. It consists of a double piston or pump, forcing the oil through a tube to the burner, worked by clockwork.

A form of reading lamp still in use is seen in section in fig. 2. The lamp is mounted on a standard on which it can be raised or lowered at will, and fixed by a thumb screw. The oil reservoir is in two parts, the upper \( a \) being an inverted flask which fits into \( b \), from which the burner is directly fed through the tube \( d \); \( k \) is an overflow cup for any oil that escapes at the burner, and it is pierced with air-holes for admitting the current of air to the centre tube of the Argand burner. The lamp is filled with oil by withdrawing the flask \( ac \), filling it, and inverting it into its place. The under reservoir \( b \) fills itself to the burner level \( e \), on a line with the mouth of \( a \). So soon as that level is reached, a bubble of air gets to the upper reservoir, and oil again fills up \( b \) to the level \( e \).

The modulator lamp (fig. 3), invented by Franchot about 1836, from the simplicity of its arrangement, superseded almost all other forms of mechanical lamp for use with animal and vegetable oils. The two essential features of the modulator lamp are (1) the strong spiral spring which, acting on a piston within the oil reservoir, forces the oil steadily up to the burner, and (2) the ascending tube \( C \) through which the oil passes upwards to the burner. The latter consists of two sections, the lower fixed to and passing through the piston \( A \) into the oil reservoir, and the upper turned to the burner. The lower or piston section moves within the upper, which forms a shroud enclosing nearly its whole length when the spring is fully wound up. Down the centre of the upper tube passes a wire, "the modulator," \( G \), and it is by this wire that the supply of oil to the burner is regulated. The spring exerts its greatest force on the oil reservoir when it is fully wound up, and, in proportion as it expands and descends its power decreases. But when the apparatus is wound up, the wire passing down the upper tube extends throughout the whole length of the lower and is caught in the piston, obstructing to a certain extent the free flow of the oil. In proportion as the spring unwinds, the length of the wire within the lower tube is decreased; the upward flow of oil is facilitated in the decreasing the capacity of the piston, and in the modulator the surplus oil, flowing down the wick, falls back into the reservoir and, when the piston, with which the oil flows along with the supply oil it descends into the lower side by means of leather valves \( a, a \). B represents the rack with which, when the pinion \( D \), winds up the spiral spring hard against \( E \) when the lamp is prepared for use. The modulator wire \( F \) is attached to \( G \), and \( G \) is attached to the lamp, which, when \( E \) is raised, winds up the modulator. The modulator or working is shown in figures \( 1 \) and \( 2 \); \( F G C \) illustrates the arrangement of the sheathing tubes, in the upper section of which the modulator is fixed.

As early as 1781 the idea was mooted of burning naphtha, obtained by the distillation of coal at low temperatures, for illuminating purposes, and in 1820, when coal gas was struggling into prominence, light oils obtained by the distillation of coal tar were employed in the Holliday lamp, which is still the chief factor in illuminating the street bars of the costermongers. In this lamp the coal naphtha is in a conical reservoir, from the apex of which it flows slowly down through a long metal capillary to a rose burner, which, heated by the flame, vaporizes the naphtha, and thus feeds the ring of small jets of flame escaping from its circumference.

It was in 1847 that James Young had his attention drawn to an oxidation of petroleum in the Riddings Colliery at Alfreton, in Derbyshire, and found that he could by distillation obtain from it a lubricant of considerable value. The commercial success of this material was accompanied by a failure of the supply, and, rightly imagining that as the oil had apparently come from the Coal Measures, it might be obtained by distillation from material of the same character, Young began investigations in this direction, and in 1850 started distilling oils from a shale known as the "Bathgate mineral," in this way founding the Scotch oil industry. At first little attention was paid to the fitness of the oil for burning purposes, although in the early days at Alfreton Young attempted to burn some of the lighter distillates in an Argand lamp, and later in a lamp made many years before for the consumption of turpentine. About 1855,
however, it was noticed that the lighter distillates were being shipped to Germany, where lamps fitted for the consumption of the grades of oil now known as lamp oil were being made by Stohwasser of Berlin; some of these lamps were imported, and similar lamps were afterwards manufactured by Laidlaw in Edinburgh.

In Pennsylvania in 1839 Colonel E. L. Drake’s successful boring for petroleum resulted in the flooding of the market with oil at prices never before deemed possible, and led to the introduction of lamps from Germany for its consumption. Although the first American patent for a petroleum lamp is dated 1839, that year saw forty other applications, and for the next twenty years they averaged about eighty a year.

English lamp-makers were not behind in their attempts to improve on the methods in use for producing the highest results from the various grades of oil, and in 1865 Hinks introduced the duplex burner, while later improvements in various directions, by Hinks, Silber, and Defries led to the high degree of perfection to be found in the lamps of to-day. Mineral oil for lamps as used in England at the present time may be defined as consisting of those portions of the distillate from shale oil or crude petroleum which have their flash-point above 73° F., and which are mobile enough to be fed by capillarity in sufficient quantity to the flame. The oil placed in the lamp reservoir is drawn up by the capillarity of the wick to the flame, and being there volatilized, is converted by the heat of the burning flame into a gas, a mixture of hydrogen and hydrocarbons, which is ultimately consumed by the oxygen of the air and converted into carbon dioxide and water vapour, the products of complete combustion.

To secure high illuminating power, together with a smokeless flame and only products of complete combustion, strict attention must be paid to several important factors. In the first place, the wick must be so arranged as to supply the right quantity of oil for gasification in the burner-head—the flame must be neither starved nor overfed: if the former is the case great loss of light is occasioned, while an excess of oil, by providing more hydrocarbons than the air-supply to the flame can completely burn, gives rise to smoke and products of incomplete combustion. The action of the wick depending on the capillary action of the microscopic tubes forming the cotton fibre, nothing but long-staple cotton of good quality should be employed; this should be spun into a coarse thread, with as little twist in it as possible, and from this the wick is built up. Having obtained a wick of soft texture and loose plait, it should be well dried before the fire, and when put in position in the lamp should fill the wick-holder without being compressed. It should be of such length that, hanging down to the bottom of the oil reservoir and leaving an inch or two on the bottom. Such a wick will suck up the oil in a regular and uniform way, provided that the level of the oil is not allowed to fall too low in the lamp, but it must be remembered that the first wick only acts as a filter for the oil, and that if any sediments are present it will be retained by and choke the capillary upon which the action of the wick depends, so that a wick should not be used for too long a time. A good rule is that the wick should, when new, have a thread of 2 in. on the bottom of the oil vessel, and should be discarded when these 2 in. have been burnt off.

When the lamp is lighted the oil burns with a heavy, smoky flame, because it is not able to obtain sufficient oxygen to complete the combustion, and as only are spent flakes produced, but products of incomplete combustion, such as carbon monoxide and even petroleum vapour, escape—the first named highly injurious to health, and the second of an offensive odour. To supply the necessary amount of oxygen to the flame, an artificial draught has to be created which shall impinge upon the bottom of the flame and sweep upwards over its surface, giving it rigidity, and by completing the combustion in a shorter period of time than could be done otherwise, increasing the calorific intensity and thus raising the carbon particles in the flame to a far higher incandescence so as to secure a greater illuminating power. This in practice has been done in two ways, first by drawing in the air by the up-suck of the heated and expanded products of combustion in a chimney fitted over the flame, and secondly by creating a draught from a small clockwork fan in the base of the lamp. It is necessary to break the initial rush of the draught: this is mostly effected by disks of perforated metal in the base of the burner, called *diffusers*, while the metal dome which surrounds and rises slightly above the wick holder serves to deflect the air on to the flame, as in the Wanzer lamp. These arrangements also act to a certain extent as regenerators, the air passing over the heated metal surfaces being warmed before reaching the flame, while disks, cones, buttons, perforated tubes, inner air-tubes, &c., have been introduced to increase the illuminating power and complete the combustion.

According to Sir Boveryton Redwood, duplex burners which give a flame of 24 candle-power have an average oil consumption of 50 grains per candle per hour, while Argand lamps and wick-power consume about 45 grains of oil per candle per hour. These figures were obtained from lamps of the best types, and to obtain information as to the efficiency of the lamps used in daily practice, a number of the most popular types were examined, using both American and Russian oil. The results obtained are embodied in Table I. The first noteworthy point in this table is the apparent superiority of the American over Russian oil in the majority of the lamps employed, and there is no doubt that the bulk of the lamps on the market are constructed to burn American or shale oil.

A second interesting point is that with the flat-flame lamps the Russian oil is as good as the American. What have Redwood’s authors overlooked, for the fact that after prolonged burning the Russian oil, even in lamps least suited to it, gives highly improved results. Although the average consumption with these lamps is close upon 60 grains per candle with American oil, yet some of the burners are so so expertly worked that some lamps per candle per hour is the fairest basis to take for any calculation as to cost. The dangers of the mineral oil lamp, which have been grave drawbacks in the past, have been much reduced by improvements in construction and quality, and if it were possible to abolish the cheap and dangerous rubbish sold in poor neighbourhoods, and to prevent the use of side-fillers and glass reservoirs in lamps of better quality, a still larger reduction in the number of accidents would take place. In the use of the lamp for domestic purposes only soft well-fitting wicks should be employed, and the lamp should be filled with oil each day so as never to allow it to burn too low and so leave a large space above the surface of the oil in the reservoir. The lamp should never be moved whilst alight, and it should only be put out by means of a proper extinguisher or by blowing across the top instead of down the chimney. By these means the risk of accident would be so reduced as to compare favourably with other illuminants.

Candles, oil and coal gas all emit the same products of complete combustion, viz. carbon dioxide and water vapour. The quantities of these compounds emitted from different illuminants for every candle of light per hour will be seen from the following table:

**American oil—Sp. gr. 0-7904; flash-point, 110° F.**

**Russian oil—Sp. gr. 0-623; flash-point, 83° F.**

From these it appears that if the sanitary condition of the air of a dwelling-room be measured by the amount of carbon dioxide present, as is usually done, candles are the most prejudicial to health and comfort, oil lamps less so, and gas least, an assumption
which practical experience does not bear out. The explanation of this is to be found in these facts: First, where we illuminate a room with candles or oil we are contented with a less intense and more local light than when we are using gas, and in a room of ordinary size would be more likely to use a lamp or two candles than the far higher illumination we should demand if gas were employed. Secondly, the amount of water vapour given off during the combustion of gas is greater than in the case of the other illuminants, and this causes a vapour hissing sound from the burning ridge when the oil becomes heated, and, diffusing itself about the room, causes great oppression. Also the air, being highly charged with moisture, is unable to take up so rapidly the water vapour which is always evaporating from the surface of our skin, and in this way the functions of the body receive a slight check, resulting in a feeling of depression.

A very successful type of oil lamp for use in engineering is represented by the Lucigen, Doty, and Wells lights, in which the oil is forced from a reservoir by air-pressure through a spiral heated by the flame of the lamp, and the heated oil, being then ejected partly as vapour and partly as spray, burns with a large and highly luminous flame. The great drawback to these devices is that a certain proportion of the oil spray escapes combustion and is deposited in the vicinity of the light. This form of lamp is often used for heating as well as lighting, the river of heat from the lamp falling on the walls, were heated in trays by lamps of this type at the spot where they were required. The great advantage of these lamps was that oils of little value could be employed, and the light obtained approximated to 750 candles per gallon of oil consumed. They may to a certain extent be looked upon as the forerunners of perhaps the most successful form of incandescent oil-burner.

As early as 1885 Arthur Kitson attempted to make a burner for heating purposes on the foregoing principle, i.e., by injecting oil under pressure from a fine tube into a chamber where it would be heated by the waste heat escaping from the flame below, the vapour so produced being made to issue from a small jet under the pressure caused by the initial air-pressure and the expansion in the gasifying tube. This jet of gas was then led into what was practically an atmospheric burner, and drew in with it sufficient air to cause its combustion with a non-luminous blue flame of great heating power. At the time when this was first done, the Welsbach mantle had not yet reached the period of commercial utility, and attempts were made to use this flame for the generation of light by consuming it in a mantle of fine platinum gauge, which, although giving a very fine illuminating effect during the first few hours, very soon shared the fate of all platinum mantles—that is, carbonization of the platinum surface took place, and destroyed its power of light emissivity. It was not until 1893 that the perfecting of the Welsbach mantle enabled this method of consuming the oil to be employed. The Kitson lamp, and also the Empire lamp on a similar principle, have given results which ought to ensure their future success, the only drawback being that they need a certain amount of intelligent care to keep them in good working order.

Oil gas and oil vapours differ from coal gas merely in the larger proportion and greater complexity of the hydrocarbon molecules present, and to render the oil flame available for incandescent lighting it is only necessary to connect the oil gas-outlet of the lamp to a source of sufficient proportion of air before it arrives at the point of combustion. But with gases so rich in hydrocarbons as those developed from oil it is excessively difficult to get the necessary air intimately and evenly mixed with the gas in sufficient proportion to bring about the desired result. If even coal gas be taken and mixed with 2.27 volumes of air, its luminosity is destroyed, but such a flame would be useless with the incandescent mantle, as if the non-luminous flame be superheated a certain proportion of its luminosity will reappear. When such a flame is used with a mantle the superheating effect of the mantle itself very quickly leads to the decomposition of the hydrocarbons and blackening of the mantle, which not only robs it of its light-giving powers, but also rapidly ends its life. If, however, the proportion of air be increased, the appearance of the flame becomes considerably altered, and the hydrocarbon molecules being burnt up before contact with the heated surface of the mantle, all chance of blackening is avoided.

On the first attempts to construct a satisfactory oil lamp which could be used with the incandescent mantle, this trouble showed itself to be a most serious one, as although it was comparatively easy to take a circular-wick flame fed by an excess of air, to make it non-luminous, the moment the mantle was put upon this, blackening quickly appeared, while when methods for obtaining a further air supply were devised, the difficulty of producing a flame which would burn for any reasonable time became apparent. In order to make this lamp highly illuminating and yet to a certain extent prevent the acquiring a non-luminous flame, the first attempts proved a serious drawback. This trouble has mitigated against most of the incandescent oil lamps placed upon the market.

It soon became evident that if awick were employed the difficulty of getting it perfectly symmetrical was a serious matter, and that if it could be arranged to be utilized by a chamber in which there could be complicated with air would give the non-luminous flame. In the earlier forms of incandescent oil lamps the general idea was to such the vapour of the lamp that the oil was vaporized or gasified by the heat of the burner. An air supply was then drawn up through a tube passing through the centre of the wick-tube, while a second air current was so arranged as to discharge itself almost horizontally upon the burning cap of the lamp, in this way giving a non-luminous and very hot flame, which if kept very carefully adjusted and the burner was not too much mixed with air, the heat it would have a certain degree of perfection, but have not so far attained sufficient regularity of action to make them commercial successes. One of the most successful was devised by F. Alttman, in which an ingenious method was employed for vaporizing the wick by the heat of a little oil lamp in a lower and separate chamber, and the mixture of oil gas and steam was then burnt in a burner-head with a special arrangement of air supply, heating a mantle suspended above the burner-head. A perfect petrol incandescent lamp has not yet been made, but the results thus obtained show that when the right system has been found a very great increase in the amount of light developed from the petroleum may be expected. In one lamp experimented with for some time it was easy to obtain 350 candle hours per gallon of oil, or three times the amount of light obtainable from the oil when burnt under ordinary conditions.

Before the manufacture of coal-gas had become so universal as it is at present, a favourite illuminant for country mansions and even villages where no coal-gas was available was a mixture of air with the vapour of very volatile hydrocarbons, which is generally known as "air-gas." This was produced by passing a current of dry air through or over petroleum spirit or the light hydrocarbons distilled from tar, when sufficient of the hydrocarbon was taken up to give a luminous flame in flat illumination. Argand burner and the same as coal-gas, the trouble being that it was difficult to regulate the amount of hydrocarbon held in suspension by the air, as this varied very widely with the temperature. As coal-gas spread to the smaller villages and electric lighting became utilized in large houses, the use of air-gas died out, but with the general introduction of the incandescent mantle it again came to the front. In the earlier days of this revival, air-gas rich in hydrocarbon vapour was made and was further aerated to give a non-luminous flame by burning it in an atmospheric burner.

One of the best illustrations of this system was the Aerogene gas introduced by a number of railway companies to light a number of villages and railway stations on the continent of Europe. In this arrangement a revolving coil of pipes continually dips into petroleum spirit contained in a cylinder, and the air passed into the cylinder through the coil of pipes becomes highly carburized by the gas and is, from this reason contains a considerable proportion of air, the resulting gas when burnt in an ordinary burner gives a luminous flame; it can be used in atmospheric burners differing little from those of the ordinary type. With an ordinary Welsbach "C" burner air-gas can be used, but if it be considered when any air is used, the high illuminating power being due to the fact that the gas is under a pressure of from 6 to 8 in. With such a gas, containing a considerable percentage of hydrocarbon vapour, any leakage into the air is to the advantage of the burner, so that it may be regulated, in the same way that coal-gas would do, but inasmuch as mixtures of the vapour of petroleum spirit and air are only explosive for a very short range, that is, from 1:25 to 5:1, some systems have been
introduced in which by keeping the amount of petroleum vapour at 2% and burning the gas under pressure in a specially constructed non-aerating mantle burner, not only has it been found possible to produce a very large volume of gas per gallon of spirit employed, but the gas is itself non-explosive, increase in the amount of gas taking it farther away from the explosive limit. The Hooker, De Laitte and several other systems have been based upon this principle.

2. GAS LIGHTING

In all measurements of illuminating value the standard of comparison used in England is the light yielded by a sperm candle of the size known as "sixes," i.e. six to the pound, consuming 120 grains of sperm per hour, and although in photometric work slight inequalities in burning have led to the candle being discarded in practice, the standard lamps burning pentane vapour which have replaced them are arranged to yield a light of ten candles, and the photometric results are expressed as before in terms of candles.

When William Murdoch first used coal-gas at his Redruth home in 1770, he burnt the gas as it escaped from the open end of a small iron tube, but soon realizing that this plan entailed very large consumption of gas and gave a very small amount of light, he welded up the end of his tube and bored three small holes in it, so arranged that they formed three divergent jets of flame. From the shape of the flame so produced this burner received the name of the "cockspur" burner, and it was the one used by Murdoch when in 1807 he fitted up an installation of gas lighting at Phillips & Lee's works in Manchester. This—

the earliest form of gas burner—gave an illuminating value of a little under one candle per cubic foot of gas consumed, and this duty was slightly increased when the burner was improved by widening up the welded end of the tube and making a series of small holes in line and close together, the jets of flame from which gave the burner the name of the "cockcomb." It did not need much inventive faculty to replace the line of holes by a saw-cut, the gas issuing from which burnt in a sheet, the shape of which led to the burner being called the "batswing." This was followed in 1820 by the discovery of J. B. Neilson, of Glasgow, whose name is remembered in connexion with the use of the hot-air blast in iron-smelting, that, by allowing two flames to impinge upon one another so as to form a flat flame, a slight increase in luminosity was obtained, and after several preliminary stages the union jet or "fishtail" burner was produced. In this form of burner two holes, bored at the necessary angle in the same nipple, caused two streams of gas to impinge upon each other so that they flattened themselves out into a sheet of flame. The flames given by the batswing and fishtail burners differed in shape, the former being wide, and of but little height, whilst the latter was much higher and more narrow. This factor ensured for the fishtail a greater amount of popularity than the batswing burner had obtained, as the flame was less affected by draughts and could be used with a globe, although the illuminating efficiency of the two burners differed little.

In a lecture at the Royal Institution on the 20th of May 1853, Sir Edward Frankland showed a burner he had devised for utilizing the heat of the flame, to raise the temperature of the air supply necessary for the combustion of the gas. The burner was an Argand of the type then in use, consisting of a metal ring pierced with holes so as to give a circle of small jets, the ring of flame being surrounded by a chimney. But in addition to this chimney, Frankland added a second external one, extending some distance below and closed at the bottom by a glass plate fitted air-tight to the pillar carrying the burner. In this way the air needed for the combustion of the gas had to pass down the space between the two chimneys, and in so doing became highly heated, partly by contact with the hot glass, and partly by radiation. Sir Edward Frankland estimated that the temperature of the air reaching the flame was about 500°F. In 1854 a very similar arrangement was brought forward by the Rev. W. R. Bowditch, and, as a large amount of publicity was given to it, the inception of the regenerative burner was generally ascribed to Bowditch, although undoubtedly due to Frankland.

The principle of regeneration was adopted in a number of lamps, the best of which was brought out by Friedrich Siemens in 1879. Although originally made for heating purposes, the light given by the burner was so effective and superior to anything obtained up to that time that it was with some slight alterations adapted for illuminating purposes.

Improvements followed in the construction and design of the regenerative lamp, and when used as an overhead burner it was found that not only was an excellent duty obtained per cubic foot of gas consumed, but that the lamp could be made a most efficient engine of ventilation, as an enormous amount of vitiated air could be withdrawn from the upper part of a room through a flue in the ceiling space. So marked was the increase in light due to the regeneration that a considerable number of burners working on this principle were introduced, some of them like the Wenham and Cromartie coming into extensive use. They were, however, costly to instal, so that the flat flame burner retained its popularity in spite of the fact that its duty was comparatively low, owing to the flame being drawn out into a thin sheet and so exposed to the cooling influence of the atmosphere.

Almost at the same time that Murdoch was introducing the cockscomb and cockspur burners, he also made rough forms of Argand burner, consisting of two concentric pipes between which the gas was led and burnt with a circular flame. This form was soon improved by filling in the space between the tubes with a ring of metal, bored with fine holes so close together that the jets coalesced in burning and gave a more satisfactory flame, the air necessary to keep the flame steady and ensure complete combustion being obtained by the draught created by a chimney placed around it. When it began to be recognized that the temperature of the flame had a great effect upon the amount of light emitted, the iron tubes, which had been universally employed, both in flat flame and Argand burners, were replaced by steatite or other non-conducting material of similar character, to prevent as far as possible heat from being withdrawn from the flame by conduction.

In 1880 the burners in use for coal-gas therefore consisted of flat flame, Argand, and regenerative burners, and the duty given by them with a 16-candle gas was as follows:

The luminosity of a coal-gas flame depends upon the number of carbon particles liberated within it, and the temperature to which they can be heated. Hence the light given by a flame of coal-gas can be augmented by (1) increasing the number of the carbon particles, and (2) raising the temperature to which they are exposed. The first process is carried out by enrichment (see GIs: Manufacture), the second is best obtained by regeneration, the action of which is limited by the power possessed by the material of which burners are composed to withstand the superheating. Although with a perfectly made regenerative burner it might be possible for a short time to get a duty as high as 16 candles per cubic foot from ordinary coal-gas, such a burner constructed of the ordinary materials would last only a few hours, so that for practical use and a reasonable life for the burner to candles per cubic foot was about the highest commercial duty that could be reckoned on. This limitation naturally caused inventors to search for methods by which the emission of light could be obtained from coal-gas otherwise than by the incandescence of the carbon particles contained within the
in a solution of a metallic salt for lighting purposes, and in 1885 he patented his first commercial mantle. The oxides used in these mantles were zirconia, lanthania, and yttria, but these were so fragile as to be practically useless, whilst the light they emitted was very poor. Later he found that the oxide of thorium—thoria—in conjunction with other rare earth oxides, not only increased the light-giving powers of the mantle, but added considerably to its strength, and the use of this oxide was protected by his 1886 patent. Even these mantles were very unsatisfactory until it was found that the purity of the oxides had a wonderful effect upon the amount of light, and finally came the great discovery that it was a trace of ceria in admixture with the thoria that gave the mantle the marvellous power of emitting light.

Certain factors limit the number of oxides that can be used in the manufacture of an incandescent mantle. Atmospheric influences must not have any action upon them, and they must be sufficiently refractory not to melt or even soften to any extent at the temperature of the flame; they must also be non-volatile, whilst the shrinkage during the process of "burning off" must not be excessive. The following table gives the light- emissivity from pure and commercial samples of the oxides which most nearly conform to the above requirements; the effect of impurity upon the lighting power will be seen to be most marked.

| **Of these oxides thoria when tested for shrinkage, duration, and strength, stands pre-eminent. It is also possible to employ zirconium oxide and lanthanum oxide. Zirconia has the drawback that in the hottest part of the flame it is liable not only to shrinkage and semi-fusion, but also to slow volatilization, and the same objection holds good with respect to alumina. With thoria the shrinkage is smaller than with any other known substance, and it possesses very high refractory powers.**

The factor which gives thoria its pre-eminence as the basis of the mantle is that in the conversion of thorium nitrate to thorin oxide by an enormous expansion takes place, the oxide occupying more than ten times the volume of the nitrate. This means that the mass is highly spongy, and contains an enormous number of little air-cells which must render it an excellent thermal conductor. A mantle made with thoria alone gives practically no light. But the power of light-emissivity is awakened by the addition of a small trace of ceria; and careful experiment shows that as ceria is added to it little by little, the light which the mantle emits grows greater and greater, until the ratio of 99% of thorium and 1% of ceria is reached, when the maximum illuminating effect is obtained. The further addition of ceria causes gradual diminution of light, until, when with some 10% of ceria has been added, the light given by the mantle is again almost inappreciable. When cerium nitrate is converted by heat into cerium oxide, the expansion which takes place is practically nil, the ceria obtained from a gramme of the nitrate occupying about the same space as the original nitrate. This is brought about by the ratio of ceria to thoria is as 1:99; by volume it is only as 1:99.

The most successful form of mantle is made by taking a cylinder of cotton net about 8 in. long, and soaking it in a solution of nitrates of the requisite metals until the microscopic fibres of the cotton are entirely filled with liquid. A longer soaking is not advantageous, as the acid nature of the liquid employed tends to weaken the fabric and render it more delicate to handle. The cotton is then wrung out to free it from the excess of liquid, and one end is sewn together with an asbestos as a layer of the same material on the plate, the wire being fixed across the constant portion to provide a support by which the mantle may be held by the carrying rod, which is either external to the mantle, or (as is most often the case) fixed centrally in the burner head. It is then ready for "burning off," a process in which the organic matter is removed and the nitrates are
converted into oxides. The flame of an atmospheric burner is first applied to the constrained portion at the top of the mantle, whereupon the cotton gradually burns downwards, the shape of the mantle to a great extent depending on the regularity with which the combustion takes place. A certain amount of carbon is left behind after the flame has died out, and this is burnt off by the judicious application of a flame from an atmospheric blast burner to the interior. The action which takes place during the burning off is as follows: The cellulose tubes of the fibre are filled with the crystallized nitrates of the metals used, and as the cellulose burns the nitrates decompose, giving up oxygen and forming fusible nitrates, which in their semiliquid condition are rendered coherent by the rapid expansion as the oxide forms. As the action continues the nitrates become oxides, losing their fusibility, so that by the time the organic matter has disappeared a coherent thread of oxide is left in place of the nitrate-laden thread of cotton. In the early days of incandescence lighting it was practised to set out mantles as the process was known by which the burnt mantle could be rendered sufficiently strong to bear carriage. As the success of a mantle depends upon its fitting the flame, and as the burning off requires considerable skill, this was a great difficulty. Moreover the acid nature of the nitrates in the fibres rapidly rotted them, unless they had been subjected to the action of ammonia gas, which neutralized any excess of acid. It was discovered, however, that the burnt-off mantle could be temporarily strengthened by dipping it in collodion, a solution of soluble guncotton in ether and alcohol together with a small castor-oil or similar material to prevent excessive shrinkage when drying. When the mantle was removed from the solution a thin film of solid collodion was left on it, and this could be burned away when required.

After the Welsbach mantle had proved itself a commercial success many attempts were made to evade the monopoly created under the patents, and in the same way that the thorium used in the Welsbach mantle, the zirconia being added merely to strengthen the structure. These mantles enjoyed considerable popularity owing to the yellowish pink light they emitted, but, although they could give an initial illumination equal to that of the Welsbach mantle, they rapidly lost their light-giving power owing to the slow volatilization of the oxides of chromium and aluminium.

Another method of making the mantle was first to produce a bundle of fibres of cotton saturated with oxides of cerium, and alumina, and then to apply it with a mixture of 99% thorium and 1% ceria. This modification seems to improve the initial amount of light given by the mantles. In the Voelker mantle a basis of thorium was produced by being melted into a number of oxides in the electric furnace. The fused mass was then dissolved in the strongest nitric acid, and diluted with absolute alcohol to the necessary degree. A very good mantle having great lasting power was thus produced. It was claimed that the process of fusing the materials together in the electric furnace altered the composition in some unexpected way, but the true explanation is probably that all water of hydration was contained in the oxides of chromium and aluminium.

in the process by which the saturated fabric can be so prepared as to be easily burnt off by the consumer on the burner on which it is to be used, in this way doing away with the initial cost of burning off, shaping, hardening and collodionizing.

Since 1897 inventions have been patented for methods of intensifying the light produced by burning gas under a mantle and increasing the light generated per unit volume of gas. The systems have either been self-intensifying or have depended on supplying the gas (or gas and air) under an increased pressure. Of the self-intensifying systems those of Lucas and Scott-Snell have been the most successful. A careful study has been made by the inventor of the Lucas light of the influence of various sizes and shapes of chimneys in the production of draught. The specially formed chimney used exerts a suction on the gas flame and air, and the burner and mantle are so constructed as to take full advantage of the increased air supply, with the result that the candle power given by the mantle is considerably augmented. With the Scott-Snell system the results obtained are about the same as those given by the Lucas light, but in this case the waste heat from the burner is used to operate a plunger working in the town of the lamp which sucks in and delivers gas to the burner. Both these systems are widely used for public lighting in many large towns of the United Kingdom and the continent of Europe.

The other method of obtaining high light-power from incandescent gas burners necessitates the use of some form of motive power in order to place the gas, or both gas and air, under an increased pressure. The gas compressor is worked by a water motor, hot air or gas engine; a low pressure water motor may be efficiently driven by water from the main, but with large installations it is more economical to drive the compressor by a gas engine. To overcome the intermittent flow of gas caused by the stroke of the engine, a regulator on the floating bell principle is placed after the compressor; the pressure of gas in the apparatus governs automatically the flow of gas to the engine. With the Sugg apparatus for high power lighting the gas is brought from the district pressure, which is equal to about 23 in. of water, to an average of 12 in. water pressure. The light obtained by this system when the gas pressure is 01 in. is 300 candle power with an hourly consumption of 10 cub. ft. of gas, equivalent to 30 candles per cubic foot, and with a gas pressure equal to 1.4 in. of water 400 candles are obtained with an hourly consumption of 123 cub. ft., which represents a duty of 32 candles per cubic foot of gas consumed. High pressure incandescent lighting makes it possible to burn a far larger volume of gas in a given time under a mantle than is the case with low pressure lighting, so as to create centres of high total illuminating value to compete with arc lighting in the illumination of large spaces, and the Lucas, Keith, Scott-Snell, Millennium, Selas, and many other pressure systems answer most admirably for this purpose.

The light given by the ordinary incandescent mantle burning in an upright position tends rather to the upward direction, because owing to the slightly conical shape of the mantle the maximum light is emitted at an angle a little above the horizontal. Inasmuch as for working purposes the surface that a mantle illuminates is at angles below 45° from the horizontal, it is evident that a considerable loss of efficient lighting is brought about, whilst directly under the light the burner and mantles throw a strong shadow. To avoid this trouble attempts have from time to time been made to produce inverted burners which should heat a mantle suspended below the mouth of the burner. As early as 1882 Clamond made what was practically an inverted gas and air blowpipe to use with his incandescent basket, but it was not until 1900-1901 that the inverted mantle became a possibility. Although there was a strong prejudice against it at first, as soon as a really satisfactory burner was introduced, its success was quickly placed beyond doubt. The inverted mantle has now proved itself one of the chief factors in the enormous success achieved by incandescent mantle lighting, as the illumination given by it is far more efficient than with the upright mantle, and it also lends itself well to ornamental treatment.

When the incandescent mantle was first introduced, in 1886 an ordinary laboratory Bunsen burner was experimentally employed, but unless a very narrow mantle just fitting the top of the tube was used the flame could not be got to fit the mantle, and it was only the extreme outer edge of the flame which endowed the mantle fabric with the high incandescent. A wide burner top was then placed on the Bunsen tube so as to spread the flame, and a larger mantle became possible, but it was then found that the slowing down of the rate of flow at the mouth of the burner owing to its enlargement caused flashing or firing back, and to prevent this a wire gauze covering was fitted to the burner head; and in this way the 1886-1887 commercial Welsbach burner was produced. The length of the Bunsen tube, however, made an unsightly fitting, so it was shortened, and the burner head made to slip over it, whilst an external lighting back plate was added. The form of the "C" burner thus arrived at has undergone no important further change. When later on it was desired to make incandescent burners capable of burning gas without raising the pressure, to increase the air supply, the long Bunsen tube was reverted to, and to the Kern, Bandsept, and other burners of this class all have a greater total length than the ordinary burners. To secure proper mixing of the air and gas, and to prevent flashing back, they all have heads fitted with baffles, perforations, gauze, and other devices which oppose considerable resistance to the flow of the stream of air and gas.

In 1900, therefore, two classes of burner were in commercial existence for incandescent lighting—(1) the short burner with chimney, and (2) the long burner without chimney. Both classes had the burner mouth closed with gauze or similar device, and both needed as an essential that the mantle should fit closely to the burner head.

Prior to 1900 attempts had been made to construct a burner in which an incandescent mantle should be suspended head downwards. Inventors all turned to the overhead regenerative gas lamps of the Wenham type, or the inverted blowpipe used by Clamond, and in attempting to make an inverted Bunsen employed either artificial pressure to the gas or the air, or both, or else enclosed the burner and mantle in a globe, and by means of a long chimney created a strong draught. These burners also were all regenerative and aimed at heating the air or gas or mixture of the two, and they had the further drawback of being complicated and costly. Regeneration was dependent on adiabatic or isothermal actions that liberate the carbon particles upon which the luminosity of a flame is dependent, and also increases the temperature; but with the mixture of air and gas in a Bunsen regeneration is not a great gain when low and is a drawback when intense, because incomplete combustion between the oxygen of the air and the coal-gas before the burner head is reached, the proportions of air and gas are disturbed, and the flame instead of being non-luminous shows slight luminosity and tends to blacken the mantle.

The early attempt to burn a mantle in an inverted position without regeneration or artificial pressure or draught was made by H. A. Kent in 1897, and he used, not an inverted Bunsen, but one with the top elongated and turned over to form a siphon, so that the flow of admixture of air and gas was below the level of the burner head, and was therefore kept away from the products of combustion.

In 1900 J. Bernt and E. Cèrvenka set themselves to solve the problem of making a Bunsen burner which should consume gas under ordinary pressure in an inverted mantle. They took the short Bunsen burner, as found in the most commonly used upright incandescent burners, and fitted to it a long tube, preferably of non-conducting material, which they called an isolator, and which is designed to keep the flame at a distance from the Bunsen. They found that it burnt fairly well, and that the tendency of the flame to burn or lap back was lessened, but that the hot up-current of heated air and products of combustion streamed up to the air holes of the Bunsen, and by contaminating the air supply caused the flame to pulsate. They then fixed an inverted cone on the isolator to throw the products of combustion outwards and away from the air holes, and found that the addition of this "deflecting cone" steadied the flame. Having obtained a satisfactory flame, they attacked
ELECTRIC

LIGHTING

659

or chemically impregnated carbons, or so-called flame arcs, and arcs formed with metallic or oxide electrodes, such as magnetite. A continuous current arc is formed with an electric current flowing always in the same direction; an alternating current arc is formed with a periodically reversed current.

An open arc is one in which the carbons or other material forming the arc are freely exposed to the air; an enclosed arc is one in which they are included in a glass vessel. If carbons impregnated with various salts are used to colour or increase the light, the arc is called a chemical or flame arc. The carbons or electrodes may be arranged in line one above the other, or they may be inclined so as to project the light downwards or more in one direction. In a carbon arc if the current is continuous the positive carbon becomes much hotter at the end than the negative, and in the open air it is worn away, partly by combustion, becoming hollowed out at the extremity of the positive carbon, which becomes pointed, and also wears away, though much less quickly than the positive. In the continuous-current open arc the greater part of the light proceeds from the highly incandescent positive crater. When the arc is examined through dark glasses, or by the optical projection of its image upon a screen, a violet band or stream of vapour is seen to extend between the two carbons, surrounded by a nebulus golden flame or aureole.

If the carbons are maintained at the right distance apart the arc remains steady and silent, but if the carbons are impure, or the distance between them too great, the true electric arc rapidly changes its place, flickering about and frequently becoming extinguished; when this happens it can only be restored by bringing the carbons once more into contact. If the current is alternating, then the arc is symmetrical, and both carbons possess nearly the same appearance. If it is enclosed in a vessel nearly air-tight, the rate at which the carbons are burnt away is greatly reduced, and if the current is continuous the positive carbon is no longer cratered out and the negative no longer so much pointed as in the case of the open arc.

Davy used for his first experiments rods of wood charcoal which had been heated and plunged into mercury to make them better conductors. Not until 1833 was it proposed by J. B. L. Foucault to employ pencils cut from the hard graphitic carbon deposited in the interior of gas retorts. In 1846 W. Green and W. E. Stait patented a process for manufacturing carbons for this purpose, but only after the invention of the Gramme dynamo in 1870 any great demand arose for them. F. P. É. Carré in France in 1876 began to manufacture arc lamp carbons of high quality from coke, lampblack and syrup. Now they are made by taking some specially refined form of finely divided carbon, such as the soot or lampblack formed by cooling the smoke of burning paraffin or tar, or by the carbonization of organic matter, and making it into a paste with gum or syrup. This paste is forced through dies by means of a hydraulic press, the rods thus formed being subsequently baked with such precautions as to preserve them perfectly straight. In some cases they are cored, that is to say, have a longitudinal hole down them, filled in with a softer carbon. Sometimes they are covered with a thin layer of copper by electro-deposition. They are supplied for the market in sizes varying from 4 or 5 to 30 or 40 millimetres in diameter, and from 8 to 16 in. in length. The value of carbons for arc lighting greatly depends on their purity and freedom from ash in burning, and on perfect uniformity of structure. For ordinary purposes they are generally round in section, but for certain special uses, such as lighthouse work, they are made flattened or with a star-shaped section. The positive carbon is usually of larger section than the negative. For continuous-current arcs a cored carbon is generally used as a positive, and a smaller solid carbon as a negative. For flame arc lamps the carbons are specially prepared by impregnating them with salts of calcium, magnesium and sodium. The calcium gives the best results. The rod is usually of a composite type. The outer zone is pure carbon to give strength, the next zone contains carbon mixed with the metallic salts, and the inner core

the problem of the burner head. Experiments showed that the burner head must be not only open but also of the same size or smaller than the burner tube, and that by projecting it downwards into the mantle and leaving a space between the mantle and the burner head the maximum mantle surface heated to incandescence was obtained. It was also found that the distance which the burner head projects into the mantle is equivalent to the same amount of extra water pressure on the gas, and with a long mantle it was found useful under certain conditions to add a cylinder or sleeve with perforated sides to carry the gas still lower into the mantle. The principles thus set forth by Kent, Bernt and Czernyvaska form the basis of construction of all the types of inverted mantle burners which so greatly increased the popularity of incandescent gas lighting at the beginning of the 20th century, whilst improvements in the shape of the mantle for inverted lighting and the methods of attachment for the burners or metal sleeves which were used were also achieved.

The wonderful increase in the amount of light that is obtained from gas by the aid of the incandescent gas mantle is realized when one compares the 1 to 3 candles per cubic foot given by the burners used in the middle of the 19th century with the duty of incandescent burners, as shown in the following table:

3. Electric Lighting.

Electric lamps are of two varieties: (1) Arc Lamps and (2) Incandescent or Glow Lamps. Under these headings we may briefly consider the history, physical principles, and present practice of the art of electric lighting.

1. Arc Lamps.—If a voltaic battery of a large number of cells has its terminal wires provided with rods of electrically-conducting carbon, and these are brought in contact and then slightly separated, a form of electric discharge takes place between them called the electric arc. It is not quite certain who first observed this effect of the electric current. The statement that Sir Humphry Davy, in 1801, first produced and studied the phenomenon is probably correct. In 1808 Davy had provided for him at the Royal Institution a battery of 2000 cells, with which he exhibited the electric arc on a large scale.

The electric arc may be produced between any conducting materials maintained at different potentials, provided that the source of electric supply is capable of furnishing a sufficiently large current; but for illuminating purposes the use of hard graphitic carbon are most convenient. If some source of continuous electric current is connected to rods of such carbon, first brought into contact and then slightly separated, the following facts may be noticed: With a low electromotive force of about 50 or 60 volts no discharge takes place until the carbons are in actual contact, unless the insulation of the air is broken down by the passage of a small electric spark. When this occurs, the space between the carbons is filled at once with a flame or luminous vapour, and the carbons themselves become highly incandescent at their extremities. If they are horizontal the flame takes the form of an arch springing between their tips; hence the name arc. This varies somewhat in appearance according to the nature of the current, whether continuous or alternating, and according as it is formed in the open air or in an enclosed space to which free access of oxygen is prevented. Electric arcs between metal surfaces differ greatly in colour according to the nature of the metal. When formed by an alternating current of high electromotive force they resemble a lambent flame, flickering and producing a somewhat shrill humming sound.

Electric arcs may be classified into continuous or alternating current arcs, and open or enclosed arcs, carbon arcs with pure
is the same but less compressed. In addition to the metallic salts a flux has to be introduced to prevent the formation of a non-conducting ash, and this renders it desirable to place the carbons in a downward pointing direction to get rid of the slag so formed. Bremer first suggested in 1888 for this purpose the fluorides of calcium, strontium or barium. When such carbons are used to form an electric arc the metallic salts develop and produce a flame round the arc which is strongly coloured, the object being to produce a warm yellow glow, instead of the somewhat violet and cold light of the pure carbon arc, as well as a greater emission of light. As noxious vapours are however given off, flame arcs can only be used out of doors. Countless researches have been made on the subject of carbon manufacture, and the art has been brought to great perfection.

Special manuals must be consulted for further information (see particularly a treatise on Carbon making for all electrical purposes, by F. Jeth, London). The physical phenomena of the electric arc are best examined by forming a carbon arc between two carbon rods of the above description, held in line in a special apparatus, and arranged so as to be capable of being moved to or from each other with a slow and easily regulated motion.

An arrangement of this kind is called a hand-regulated arc lamp (fig. 4). If such an arc lamp is connected to a source of electric supply having an electromotive force preferably of 100 volts, and if some resistance is included in the circuit, say about 5 ohms, a steady and continuous arc is formed when the carbons are brought together and then slightly separated. Its appearance may be most conveniently examined by projecting its image upon a screen of white paper by means of an achromatic lens. A very little examination of the distribution of light from the arc shows that the illuminating or candle-power is not the same in different directions. If the carbons are vertical and the positive carbon is the upper of the two, the illuminating power is greatest in a direction at an angle inclined about 40 or 50 degrees below the horizon, and at other directions has different values, which may be represented by the lengths of radial lines drawn from a centre, the extremities of which define a curve called the illuminating curve of the arc lamp (fig. 5). Considerable differences exist between the forms of the illuminating-power curves of the continuous and alternating current and the open or enclosed arcs. The chief advantage of the emitted light proceeds from the incandescent crater, hence the form of the illuminating-power curve, as shown by A. P. Trotter in 1892, is due to the apparent area of the crater surface which is visible to an eye regarding the arc in that direction. The form of the illuminating-power curve varies with the length of the arc and relative size of the carbons. Leaving out of account for the moment the properties of the arc as an illuminating agent, the variable factors with which we are concerned are (i.) the current through the arc; (ii.) the potential difference of the carbons; (iii.) the length of the arc; and (iv.) the size of the carbons. Taking in the first place the typical direct-current arc between solid carbons, and forming arcs of different lengths and with carbons of different sizes, it will be found that, beginning at the lowest current capable of forming a true arc, the potential difference of the carbons (the arc P.D.) decreases as the current increases. Up to a certain current strength the arc is silent, but at a particular critical value P.D. suddenly drops about 10 volts, the current at the same time rising 2 or 3 amperes. At that moment the arc begins to hiss, and in this hissing condition, if the current is still further increased, P.D. remains constant over wide limits. This drop in voltage on hissing was first noticed by A. Niaudet (La Lumière électrique, 1881, 3, p. 287). It has been shown by Mrs Ayrton (Journ. Inst. Elec. Eng. 28, 1899, p. 400) that the hissing is mainly due to the oxygen which gains access from the air to the crater, when the latter becomes so large by reason of the increase of the current as to overspread the end of the positive carbon. According to A. E. Blondel and Hans Luggin, hissing takes place whenever the current density becomes greater than about 0.5 or 0.5 ampere per square millimetre of crater area.

The relation between the current, the carbon P.D., and the length of arc in the case of the direct-current arc has been investigated by many observers with the object of giving it mathematical expression. Let V stand for the potential difference of the carbons in volts, A for the current through the arc in amperes, L for the length of the arc in millimetres, R for the resistance of the arc; and let 0, 1, 2, 3, &c., be constants. Erik Edlund in 1867, and other workers after him, considered that their experiments showed that the relation between V and L could be expressed by a simple linear equation,

\[ V = a + bL. \]

Later researches by Mrs Ayrton (Electrician, 1895, 41, p. 720), however, showed that for a direct-current arc of given size with solid carbons, the observed values of V can be represented as a function both of A and of L or the form

\[ V = a + bL + c + dL. \]

In the case of direct-current arcs formed with solid carbons, Edlund and other observers agree that the arc resistance R may be expressed by a simple straight line law, \( R = e + fL. \) If the arc is formed with cored carbons, Mrs Ayrton demonstrated that the lines expressing resistance as a function of arc length are no longer straight, but that there is a rather sudden dip down when the length of the arc is less than 3 mm.

The constants in the above equation for the potential difference of the carbons were determined by Mrs Ayrton in the case of solid carbons to be

\[ V = 58.9 + 2.97L + 11.7 + 10.5L. \]

There has been much debate as to the meaning to be given to the constant \( a \) in the above equation, which has a value apparently not far from forty volts for a direct-current arc with solid carbons. The suggestion made in 1867 by Edlund (Phil. Mag., 1868, 36, p. 358), that it implied the existence of a counter-electromotive force in the arc, was opposed by Luggin in 1880 (Wien. Ber. 98, p. 1108), Ernst Lecher in 1888 (Wied. Ann., 1888, 33, p. 609), and by Franz Stenger in 1892 (Id. 45, p. 33); whereas Victor von Lang and L. M. Arons in 1896 (Id. 58, p. 95), concluded that experiment indicated the presence of a counter-electromotive force of 29 volts. A. E. Blondel concludes, from experiments made by him in 1897 (The Electrician, 1897, 39, p. 615), that there is no counter-electromotive force in the arc greater than a fraction of a volt. Subsequently W. Duddell (Proc. Roy. Soc., 1910, 68, p. 512) described experiments tend to prove the real existence of a counter-electromotive force in the arc, probably having a thermoelectric origin, residing near the positive electrode, and of an associated lesser adiabatic e.m.f. near the negative carbon.

This fall in voltage between the carbons and the arc is not uniformly distributed. In 1894 Mrs Ayrton described the results of experiments showing that if \( V_1 \) is the potential difference between the positive carbon and the arc, then

\[ V_1 = 31.2 + 9.3 + 11L. \]

and if \( V_2 \) is the potential difference between the arc and the negative carbon, then

\[ V_2 = 7.6 + 13.6. \]

where \( A \) is the current through the arc in amperes and \( L \) is the length of the arc in millimetres.

The total potential difference between the carbons, minus the fall in potential down the arc, is therefore equal to the sum of \( V_1 + V_2 = V_A \).

Hence \( V_A = 38.9 + 22.5 + 3 - 21L. \)

The difference between this value and \( V \), the total potential difference between the carbons, gives the loss in potential
due to the true arc. These laws are simple consequences of straight-line laws connecting the work spent in the arc at the two electrodes with the other quantities. If \( W \) be the work spent in the arc on either carbon, measured by the product of the current and the potential difference, and the product of these two quantities again divided by 2, then for the positive carbon \( W = a + bA \) if the length of arc is constant, and \( W = c + dL \) if the current through the arc is constant, and for the negative carbon \( W = e + fA \).

These equations express the potential difference between the carbons and the arc was measured by using a third exploring carbon as an electrode immersed in the arc. This method, adopted by Lecher, F. Uppenborn, S. P. Thompson, and J. A. Fleming, is open to the objection that the current through the carbon may to a considerable extent disturb the distribution of potential. The total work spent in the continuous-current arc with solid carbons may, according to Mrs. Ayrton, be expressed by the equation

\[
W = 1.71 + 10.5L + (38.9 - 1.207)L A.
\]

It will thus be seen that the arc, considered as a conductor, has the property that if the current through it is increased, the difference of potential between the carbons is decreased, and in one sense, therefore, the arc may be said to act as if it were a negative resistance. Frith and Rodgers (Electrician, 1896, 38, p. 75) have suggested that the resistance of the arc should be measured by the ratio between a small increment of carbon potential difference and the resulting small increment of current in other words, by the equation \( \frac{\Delta V}{\Delta I} \), and not by the ratio simply of V: A. Considerable discussion has taken place whether an electrical resistance can have a negative value, belonging as it does to the class of scalar mathematical quantities, and is considered as an electrical conductor or arc, which resembles an intensely heated rod of magnet or other refractory oxide, the true resistance of which is decreased by rise of temperature. Hence an increase of current through such a rod of refractory oxide is accompanied by a decrease in the resistance of the arc. This, however, does not imply a negative resistance, but merely the presence of a resistance with a negative temperature coefficient.

If we plot a curve such that the ordinate are the difference of potential between the carbons and the abscissa is the current through the arc for constant length of arc, this curve is now called a characteristic curve of the arc and its slope at any point the instantaneous resistance of the arc. Other physical investigations have been concerned with the intrinsic brightness of the crater. It has been asserted by many observers, such as Blondel, Sir W. de W. Abney, S. P. Thompson, Trotter, L. J. G. Virole and others, that this is practically independent of the current passing, but great differences of opinion exist as to its value. Abney's values lie between 30 and 116. Trotter's between 80 and 170 watts per square millimetre. Blondel in 1893 made careful determinations of the brightness of the arc crater, and came to the conclusion that the brightness of the arc crater, and in that case its temperature should be raised by increasing the pressure under which the arc works. W. E. Wilson in 1893 attempted to measure the brightness of the crater under various pressures, and found that under five atmospheres the resistance of the arc appeared to increase and the temperature of the crater to fall, until at a pressure of 20 atmospheres the brightness of the crater had fallen to a dull red. In a later paper Wilson and G. F. Fitzgerald stated that these preliminary experiments were not confirmed, and their later researches throw considerable doubt on the suggestion that it is the boiling-point of carbon which determines the temperature of the crater. (See Electrician, 1895, 35, p. 290, and 1897, 38, p. 343.)

The study of the alternating-current arc has suggested a number of novel experimental problems for investigators. In this case the factors affecting the arc are the alternating current, the resistance, and illuminating power, are periodically varying; and as the electromagnetic force reverses itself periodically, at certain instants the current through the arc is zero. As a moment without extinguishing the arc, it is possible to work the electric arc from an alternating current generator without apparent intermission in the light, provided that the frequency is not much below 50. During the moment that the current is zero the carbon continues to glow. Each carbon in turn becomes, so to speak, the crater carbon, and the illuminating power is therefore symmetrically distributed. The curve of illumination is as shown in fig. 3. The nature of the variation of the current and arc P. D. can be examined by one of two methods, or their modifications, originally due to Jules Joubert and A. E. Blondel. Joubert's method, which has been perfected by many observers, consists in attaching to the shaft of the alternator or contact which closes a circuit at an assigned instant during the phase. This contact is made to complete the circuit with either voltmeter or galvanometer placed as a shunt across the carbons or in series with the arc. By this arrangement these instruments do not read, as usual, the root-mean-square value of the arc P. D. or current, but give a constant indication determined by, and indicating, the instantaneous values of these quantities at some assigned instant. By progressive variation of the phase-instant at which the contact is made, the successive instantaneous values of the electric quantities can be measured and plotted out in the form of curves. This method has been much employed by Blondel, Fleming, C. P. Steinmetz, Tobey and Walbridge, Frith, H. Görges and many others. The second method, due to Blondel, depends on the use of the oscillograph, which is a galvanometer having a needle or coil of very small periodic time of vibration, say 1899, with part of a second, so that the curve follows the variations of current passing through the galvanometer. An improved form of oscillograph, devised by Duddell, consists of two fine wires, which are strained transversely to the lines of flux of a strong magnetic field (see oscillograph). The current to be examined is made to pass up one wire and down the other, and these wires are then slightly displaced in opposite directions. A small mirror attached to the wires is thus deflected rapidly to and fro in synchronism with the variations of the current. From the mirror a ray of light is reflected which falls upon a photographic plate made to move across the field with a uniform motion. In this manner a photographic trace can be obtained of the wave form. By this method the variations of electric quantities in an alternating-current arc can be watched. The variation of illuminating power can be followed by examining and measuring the light of the arc through slits in a revolving stroboscopic disk, which is driven by a motor synchronously with the variation of current through the arc.

The general phenomena of the alternating-current arc are as follows:

- If the arc is supplied by an alternator of low inductance, and soft or carbon carbons are employed to produce a steady and silent arc, the potential difference of the carbons periodically varies in a manner not very different from that of the alternator or open circuit. If, however, hard carbons are used, the alternating-current arc is subjected to considerable deflection, the arc being essentially rectangular in shape. The current P.D. curve may then have a very different form, and becomes, in general, more rectangular in shape, usually having a high peak at the front. The arc also impresses the deformation on the current. Blondel's studies were that the shape of the current and potential curves is greatly affected by the nature of the carbons, and also by the amount of inductance and resistance in the circuit of the alternator. Blondel, W. E. Ayrton, W. E. Sumpner and Steinmetz have all observed that the alternating-current arc, when hissing or when formed with uncorroded carbons, acts like an inductive resistance, and that there is a lag between the current curves and the potential difference curves. Hence the power-factor, or ratio between the true power and the product of the root-mean-square values of arc current and carbon potential for
difference, in this case is less than unity. For silent arcs Blondel found 
the factors lying between 0.88 and 0.95, and for hissing ones, values 
such as 0.70. Ayton and Sumpner stated that the power-
factor of an arc be as low as 0.5. Joubert, as far back as 1881, noticed 
the deformation which the alternating-current arc curve shows the 
electromotive force curve of an alternator, giving an open 
circuit a simple harmonic variation of electromotive force. Tobye 
and Walbridge in 1896 gave the results of a number of observations 
taken of the current curve of an alternating-current arc in which 
the same deformation was apparent. Blondel in 1896 came to 
the conclusion that with the same alternator we can produce 
carbon P.D. curves of very varied character, according to the 
material of the core, the length of the arc, and the inductance of 
the circuit, which may be a P.D. curve with a flat top even when 
worked on a low inductance alternator.

The periodic variation of light in the alternating-current arc has 
also been the subject of inquiry. H. Görges in 1893 at Berlin 
employed a stroboscopic method to study the variations of illumin-
ing power. Fleming and Petavel employed a similar arrangement, 
removing the stroboscopic disk by a synchronous motor (Phil. Mag., 1896, 41). The light passing through slits of the disk was selected in 
particular period of the phase, and by means of a lens could be 
taken from any desired portion of the arc or the incandescent 
carbons. The light so selected was measured relatively to the mean 
value of the horizontal light emitted by the arc, and incidental 
variations were thus eliminated. They found that the light from 
any part is periodic, but owing to the slow cooling of the carbons 
never quite zero, the minimum value happening a little later 
than the zero value of the current. The light emitted by a 
particular section of the arc does not reach such a large 
maximum value as when it is the positive. The same observers 
made experiments which seemed to show that for a given 
expenditure of power in the arc the alternating current arc in 
general gives less mean spherical candle-power than the alternating 
current arc.

The effect of the wave form on the efficiency of the alternating-
current arc has engaged the attention of many workers. Rössler 
and Wedding in 1894 gave an account of experiments with alternating-current arcs produced by a alternators having electromotive force 
curves of very different wave forms, and they stated that the effi-
cency or mean spherical candle-power per watt expended in the arc 
was greatest for the flattest of the three wave forms by nearly 50.

Burnie in 1897 showed the results of experiments of the same kind. 
His conclusion was, that since the light of the arc is a function of 
the temperature, that wave form of current is most efficient which 
maintains the temperature most uniformly throughout the half period. Hence, if the current rises to a high value soon after its commencement, and is preserved at that value, or nearly 
at that value, during the phase, the efficiency of the arc will 
be greater when the current curve is more pointed or peaked. An 
important point to consider is that the arc current wave forms 
with solid carbons, with cored carbons, and with carbon and metal rods. They found that 
the arc current curve of an arc having solid carbons is not 
the same as the arc current curve of an arc having carbon and metal rods. They found that 
the arc current curve of an arc having solid carbons is not 
the same as the arc current curve of an arc having carbon and metal rods.

If a continuous-current electric arc is formed in the open air 
with a positive carbon having a diameter of about 1.5 millimeters, 
and a negative carbon having a diameter of about 9 millimeters, 
and if a current of 10 amperes is employed, the 
potential difference between the carbons is generally 
from 49 to 50 volts. Such a lamp is therefore called 
a 500-watt arc. Under these conditions the carbons each burn 
away at the rate of about 1 in. per hour, actual combustion 
placeing in the air which gains access to the highly-heated 
and negative tip; hence the most obvious means of prevent-
ing this disappearance is to enclose the arc in an air-tight glass 
Enclosed arc lamps. 

Such a device was tried very early in the history of arc 
lighting. The result of using a completely air-tight globe, how-
ever, is that the contained oxygen is removed by combustion with 
the carbon, and carbon vapour or hydrocarbon compounds diffuse 
through the enclosed space and deposit themselves on the cool 
sides of the glass, which is thereby obscured. It was, however, 
known by L. B. Marks (Electrician 31, p. 502, and 38, p. 646) 
in 1893, that if the arc is an arc 
formed with a small current and 
relatively high voltage, namely, 80 
and 15 volts, it is possible to admit air 
in such small amount that though 
the rate of combustion of the carbons 
is reduced, yet the air destroys by 
oxidation the carbon vapour escaping 
from the arc.

An arc lamp operated 
in this way is called an enclosed arc 
lamp (fig. 8). The top of the enclos-
ing bulb is closed by a gas check plug 
which admits through a small hole a 
limited supply of air. The peculiarity 
of an enclosed arc lamp operated 
with a continuous current is that the 
carbons do not burn to a crater on the 
positive, and a sharp tip or mushroom 
on the negative, but preserve nearly 
flat surfaces. This feature affects 
the distribution of the light. The 
illuminating curve of the enclosed 
arc, therefore, has not such a strongly 
marked maximum as the curve of the 
open arc, but on the other hand 
the true arc or column of incandes-
cent carbon vapour is less steady in 
position, wandering round from place 
to place on the surface of the carbons. 

As a compensation for this defect, the combustion of the carbons per hour 
in commercial forms of enclosed arc 
lamps is about one-twentieth part of that of an open arc lamp taking the same current.

It was shown by Fleming in 1890 that the column of incandes-
cent carbon vapour constituting the true arc possesses a unilateral 
is dipped into the arc so as to constitute a third pole, and if a small 
voltic battery of a few cells, with a galvanometer in circuit, 
is connected in between the middle pole and the negative carbon, 
it is found that when the negative pole of the battery is in con-
nection with the negative carbon the galvanometer indicates a 
current, but not when the positive pole of the battery is in connexion 
with the negative carbon of the arc.

Turning next to the consideration of the electric arc as a 
source of light, we have already noticed that the illuminating 
power in different directions is not the same. If we 
imagine an electric arc, formed between a pair of 
vertical carbons, to be placed in the centre of a hollow 
spheplane white painted on the interior, then it would be 
found that the various zones of the sphere are unequally 
illuminated. If the points in which the carbons when prolonged would 
intercept the sphere are called the poles, and the plane where the 
horizontal plane through the arc would intercept the sphere

![Fig. 7.](image-url)
is called the equator, we might consider the sphere divided up by lines of latitude into zones, each of which would be differently illuminated. The total quantity of light or the total illumination of each zone is the product of the area of the zone and the intensity of the light falling on the zone measured in candle-power. We might regard the sphere as uniformly illuminated with an intensity of light such that the product of this intensity and the total surface of the sphere was numerically equal to the surface integral obtained by summing up the products of the areas of all the elementary zones and the intensity of the light falling on each. This mean intensity is called the mean spherical candle-power of the arc. If the distribution of the illuminating power is known and given by an illumination curve, the mean spherical candle-power can be at once deduced (La Lumière électrique, 1890, 37, p. 415).

Let BMC (fig. 9) be a semicircle which by revolution round the diameter BC sweeps out a sphere. Let an arc be situated at A, and let the element of the circumference PQ = ds sweep out a zone of the sphere. Let the intensity of light falling on this zone be I. Then if \( \theta \) is the angle MAP and \( d \theta \) the incremental angle of arc PAQ, and if \( R \) is the radius of the sphere, we have

\[
dz = Rd\theta;\]

and, if we project the element PQ on the line DE we have

\[
e = ab = R \cos \theta \quad \text{and} \quad 1ab = R \cos \phi \theta.
\]

Let \( r \) denote the radius PT of the zone of the sphere, then

\[
\text{Hence the area of the zone swept out by PQ is equal to } 2\pi R \cos \theta \times ds = 2\pi R^2 \cos \theta \, dz.
\]

In the limit, and the total quantity of light falling on the zone is equal to the product of the mean intensity or candle-power \( I \) in the direction AP and the area of the zone, and therefore to

\[
2\pi R^2 \cos \theta \, dz.
\]

Let \( l_a \) stand for the mean spherical candle-power, that is, let \( l_a \) be defined by the equation

\[
4\pi l_a = 2\pi R^2 \Sigma (1ab)
\]

where \( \Sigma (1ab) \) is the sum of all the light actually falling on the sphere surface, then

\[
l_a = \frac{\Sigma (1ab)}{2\pi R^2} l_{\max}.
\]

where \( l_{\max} \) stands for the maximum candle-power of the arc. If, then, we set off at \( b \) a line \( bH \) perpendicular to \( DE \) and in length proportional to the candle-power of the arc unit in the direction AP, and carry out the same construction for a number of different observed candle-power readings at known angles above and below the horizon, the summits of all ordinates such as \( bH \) will define a curve DHE. The mean spherical candle-power is equal to the product of the maximum candle-power \( l_{\max} \), and a fraction equal to the ratio of the area included by the curve DHE to its circumscribing rectangle DFGE. The area of the curve DHE multiplied by \( 2\pi R \) gives us the total flux of light from the arc.

Owing to the inequality in the distribution of light from an electric arc, it is impossible to define the illuminating power by a single number in any other way than by stating the mean spherical candle-power. All such commonly used expressions as "an arc lamp of 2000 candle-power" are, therefore, perfectly meaningless.

The photo-metry of arc lamps presents particular difficulties, owing to the great difference in quality between the light radiated by the arc and that given by any of the ordinarily used light standards. (For standards of light and photometers, see photometer.) All photometry depends on the principle that if we illuminate two white surfaces respectively and exclusively by two separate sources of light, we can by moving the lights bring the two surfaces into such a condition that their illumination or brightness is the same without regard to any small colour difference. The quantitative measurement depends on the fact that the illumination produced upon a surface by a source of light is inversely as the square of the distance of the source. The trained eye is capable of making a comparison between two surfaces illuminated by different sources of light, and pronouncing upon their equality or otherwise in respect of brightness, apart from a certain colour difference; but for this to be done with accuracy the two illuminated surfaces, the brightness of which is to be compared, must be absolutely contiguous and not separated by any harsh line. The process of comparing the light from the arc directly with that of a candle or other similar flame standard is exceedingly difficult, owing to the much greater proportion and intensity of the violet rays in the arc. The most convenient practical working standard is an incandescent lamp run at a high temperature, that is, at an efficiency of about \( 2 \) watts per candle. If it has a sufficiently large bulb, and has been aged by being worked for some time previously, it will at a constant voltage preserve a constancy in illuminating power sufficiently long to make the necessary photometric comparisons, and it can itself be compared at intervals with another standard incandescent lamp, or with a flame standard such as a Harcourt pentane lamp.

In measuring the candle-power of arc lamps it is necessary to have some arrangement by which the brightness of the rays proceeding from the different sections of the arc can be measured. For this purpose the lamp may be suspended from a support, and a radial arm arranged to carry three mirrors, so that in whatever position the arm may be placed, it gathers light proceeding at one particular angle above and below this mirror and this light is reflected out finally in a constant horizontal direction. An easily-arranged apparatus enables us to determine the constant loss of light by reflection at all the mirrors, since that reflection always takes place at 45°. The ray thence horizontally can then be compared with that from any standard source of light by means of a fixed photometer, and by sweeping round the radial arm the photometric or illuminating curve of the arc lamp can be obtained.

From this we can determine the nature of the illumination which would be produced on a horizontal surface by the mean spherical or mean hemispherical arc lamp were suspended at a given distance above it. Let A (fig. 10) be an arc lamp placed horizontally, and let the arc height \( h = AB \) above a horizontal plane. Let \( AC \) be the illuminating power curve of the arc, and hence the AC the candle-power in a direction AP. The illumination (I) or brightness on the horizontal plane at \( P \) is equal to

\[
AC \cos AP/\cos (\theta + \phi) = FC/\cos (\theta + \phi),
\]

where \( x = BP \). Hence if the candle-power curve of the arc and its height above the surface are known, we can describe a curve BMN, whose ordinates PM will denote the brightness on the horizontal surface at any point \( P \). It is easily seen that this ordinate must have a maximum value at some point. This brightness is best expressed in candle-feet, given by the equation to be given by a standard candle on a white surface at a distance of 1 ft. If any number of arc lamps are placed above a horizontal plane, the brightness at any point can be calculated by adding together the illuminations due to each respectively.

The process of delineating the photometric or polar curve of intensity for an arc lamp is somewhat tedious, but the curve has the advantage of showing exactly the distribution of light in different directions. When once the mean spherical or mean hemispherical candle-power is required the process can be shortened by employing an integrating photometer such as that of C. P. Matthews (Trans. Amer. Inst. Elect. Eng., 1903, 19, p. 1465), or the lumen-meter of Lorette, which enables us to determine at one observation the total flux of light from the arc and therefore the mean spherical candle-power per watt.

In the use of arc lamps for street and public lighting, the question of the distribution of light on the horizontal surface is all-important. In order that street surfaces may be well lighted, the minimum illumination should not fall below 0·1 candle-foot, and in general, in well-lighted streets, the maximum illumination will be 1 candle-foot and upwards. By means of an illumination photometer, such as that of W. H. Preece and A. P. Trotter, it is easy to measure the illumination in candle-feet at any point in a street surface, and to plot out a number of contour lines of equal illumination. Experience has shown that to obtain satisfactory results the lamps must be placed on a high mast 20 or 25 ft. above the roadway surface. These posts are now generally made of cast iron in various ornamental forms (fig. 11), the necessary conductors for conveying the current up to the lamp being taken.
inside the iron mast. (The pair of incandescent lamps half-
way down the standard arc for use in the middle of the night,
when the arc lamp would give more light than is required; they are lighted by an automatic switch whenever the arc is extinguishe) The lamp itself is generally enclosed in an opalescent spherical globe, which is woven over with wire-netting so that in case of fracture the pieces may not cause damage. The necessary trimming, that is, the replacement of carbons, is effected either by lowering the lamp or, preferably, by carrying round a portable ladder enabling the trimmer to reach it. For the purpose of public illumination it is very usual to employ a lamp taking 10 amperes, and therefore absorbing about 500 watts. Such a lamp is called a 500-watt arc lamp, and it is found that a satisfactory illumination is given for most street purposes by placing 500-watt arc lamps at distances varying from 40 to 100 yds., and at a height of 20 to 25 ft. above the roadway. The maximum candle-power of a 500-watt arc enclosed in a roughened or ground-glass globe will not exceed 1500 candles, and that of a 6-8-ampere arc (continuous) about 900 candles. If, however, the arc is an enclosed arc with double globes, the absorption of light would reduce the effective maximum to about 200 c.p. and 120 c.p. respectively. When arc lamps are placed in public thoroughfares not less than 40 yds. apart, the illumination anywhere on the street surface is practically determined by the two nearest ones. Hence the total illumination at any point may be obtained by adding together the illuminations due to each arc separately. Given the photometric polar curves or illuminating-power curves of each arc taken outside the shade or globe, we can therefore draw a curve representing the resultant illumination on the horizontal surface. It is obvious that the higher the lamps are placed, the more uniform is the street surface illumination, but the less its average value; thus the two 10-ampere arcs placed on masts 20 ft. above the road surface and 100 ft. apart will give a maximum illumination of about 1.1 and a minimum of about 0.15 candle-feet in the interspace (fig 12). If the lamps are raised 40 ft.posts the maximum illumination will fall to 0.09, and the minimum will rise to 0.2. For this reason masts have been employed as high as 90 ft. In docks and railway yards high masts (50 ft.) are an advantage, because the strong contrasts due to shadows of trucks, carts, &c., then become less marked, but for street illumination they should not exceed 30 to 35 ft. in height. Taking the case of 10-ampere and 6-8-ampere arc lamps in ordinary opal shades, the following figures have been given by Trotter as indicating the nature of the resultant horizontal illumination:

<table>

As regards distance apart, a very usual practice is to place the lamps at spaces equal to six to ten times their height above the road surface. Blondel (Electrician, 35, p. 846) gives the following rule for the height (h) of the arc to afford the maximum illumination at a distance (d) from the foot of the lamp-post, the continuous current arc being employed:

- For naked arc
  - c.p. = 120
- For arc in rough glass globe
  - c.p. = 120
- For opaline globe
  - c.p. = 120
- For holophane globe
  - c.p. = 120

These figures show that the distribution of light on the horizontal surface is greatly affected by the nature of the enclosing globe. For street illumination naked arcs, although sometimes employed in works and factory yards, are entirely unsuitable, since the result produced on the eye by the bright point of light is to paralyse a part of the retina and contract the pupil, hence rendering the eye less sensitive when directed on feebly illuminated surfaces. Accordingly, diffusing globes have to be employed. It is usual to place the arc in the interior of a globe of from 12 to 18 in. in diameter. This may be made of ground glass, opal glass, or be a dioptric globe such as the holophane. The former two are strongly absorptive, as may be seen from the results of experiments by Guthrie and Redhead. The following table shows the astonishing loss of light due to the use of opal globes:

</tbody>
</table>

By using Trotter’s, Fredureau’s or the holophane globe, the light may be so diffused that the whole globe appears uniformly luminous, and yet not more than 20% of the light is absorbed. Taking the absorption of an ordinary opal globe into account, a 500-watt arc does not usually give more than 500 c.p. as a maximum candle-power. Even with a naked 500-watt arc the mean spherical candle-power is not generally more than 500 c.p., or at the rate of 0.95 c.p. per watt. The maximum candle-power for a given electrical power is, however, greatly dependent on the current density in the carbon, and to obtain the highest current density the carbons must be as thin as possible. (See T. Hesketh, “Notes on the Electric Arc,” Electrician, 39, p. 707.) For the efficiency of arcs of various kinds, expressed by the mean hemispherical candle power per ampere and per watt expended in the arc, the following figures were given by L. Andrews (“Long-flame Arc Lamps,” Journal Inst. Elec. Eng., 1906, 37, P. 4).

It will be seen that the flame arc lamp has an enormous advantage over other types in the light yielded for a given electric power consumption.

The practical employment of the electric arc as a means of illumination is dependent upon mechanism for automatically keeping two suitable carbon rods in the proper position, and moving them so as to enable a steady arc to be maintained. Means must be provided for holding the carbons in line, and when the lamp is not in operation they must fall together, or come together when the current is switched on, so as to start the arc. As soon as the current passes, they must be moved slightly apart, and gripped in position immediately the current reaches its right value, being
moved farther apart if the current increases in strength, and brought together if it decreases. Moreover, it must be possible for a considerable length of carbon to be fed through the lamp as required.

One early devised form of arc-lamp mechanism was a system of clock-work driven by a spring or weight, which was started and stopped by the pull of carbons upon the arc. In modern lighthouse lamps a similar mechanism is still employed. W. E. Steate (1847), J. B. L. Foucault (1849), V. L. M. Servais (1857), J. Duhouy (1858), and a host of later inventors, devised numerous forms of mechanical and clock-work lamps. The modern self-regulating type may be said to have been initiated by F. W. Hefner-Alteneck and the clutch lamp of C. F. Brush. The general principle of the former may be explained as follows. The arc has two solenoids, placed one upon the other. The upper one, a thick wire, is in series with the two carbon rods forming the arc, and hence called the series coil. Above this there is placed another solenoid of iron, which is called the shunt coil. Suppose an iron rod to be placed so as to be partly in one coil and partly in another; then when the coils are traversed by currents, the new current is attracted upon by forces tending to pull it into these solenoids. If the iron core be attached to one end of a lever, the other end of which carries the upper carbon, it will be evident that if the carbons are in contact and the current is switched on, the series coil alone will be traversed by the current, and its magnetic action will draw the lever up, clearing the arc of all its carbon and closing the circuit. This is the principle of the self-regulating arc-lamp invented by F. Krizik and L. Piette, called from its place of origin the Pielen lamp, comprises an iron core made in the shape of a double cone on a spindle (fig. 13), which is so arranged that it can move upward or downward in a tube that it can move into or out of a shunt and series coil, wound the one with the other and the thick insulated wire, and hence regulate the position of the carbon. The employment of this core is made to feed the carbons directly without the intervention of any clock-work, as in the case of the Hefner-Ateneck lamp. In the arc-lamp mechanism of this type, the lower carbon is fixed, and the upper carbon rests upon it by its own weight and that of its holder. The latter consists of a long rod passing through guides, and is embraced somewhere by a series of coiling wires, and hence held in position. In another form, the magnet is the armature of an electromagnet, the coils of which are in series with the arc. When the current passes through the magnet, the action is produced by the attraction of a ring on the upper carbon holder and hence strikes the arc. If the current diminishes in value, the upper carbon drops a little by its own weight, and the feed of the lamp is thus effected by a series of small lifts and drops of the current to the carbon (fig. 14). Another element sometimes employed in arc-lamp mechanism is the brake-wheel or rolling screw. This is a feature of one form of the Bocking and of the Crompton-Pochin systems. In these these the movement of the carbons is effected by a cord or chain which passes over a wheel, or by a rack geared with the brake wheel. When no current is passing through the lamp, the wheel is free to rotate, and all the carbons fall together; but when the current is switched on, the chain or cord passing over the brake wheel, or the brake wheel itself is gripped in some way, and at the same time the brake wheel is lifted so that the arc is struck.

Although countless forms of self-regulating device have been invented for arc lamps, nothing has survived the test of time so well as the typical mechanisms which work with carbon rods in one line, one or both rods being moved by a controlling apparatus as required. The early forms of semi-incandescent arc lamp, such as those of R. Werdermann and others, have dropped out of existence. These were not really true arc lamps, the light being produced by the incandescence of the extremity of a thin carbon rod pressed against a larger rod or block. The once famous Jablouchkoff candle, invented in 1876, consisted of two carbon rods about 4 mm. in diameter, placed parallel to each other and separated by a partition of kaolin, stearite or other refractory conductor. Alternating currents were employed, and the carbons moved in succession by a match or starter of high-resistance carbon paste which connected the ends of the rods. When this burned off, a true arc was formed between the parallel carbons, the separator volatilizing as the carbons burned away. Although much ingenuity was expended on this system of lighting between 1877 and 1881, it no longer exists. One cause of its disappearance was its relative inefficiency in light-giving power compared with other forms of carbon arc taking the same amount of power, and a second equally important reason was the waste in carbons. If the arc of the electric candle was accidentally blown out, no means of relighting existed; hence the great waste in half-burnt candles. H. Wilde, J. C. Jamin, J. Rapieff and others endeavoured to provide a remedy, but without success.

It is impossible to give here detailed descriptions of a fraction of the many arc-lamp mechanisms, and it must suffice to indicate the broad distinctions between various types. (1) Arc lamps may be either continuous-current or alternating-current lamps. For outdoor public illumination the former are greatly preferable, as with the same current intensity the illuminating power curves the light down on the road so as to prevent the glare from being too positive one. For indoor, public room or factory lighting, inverter arc lamps are sometimes employed. In this case the positive carbon in the lower lamp, and the lamp is carried in an inverted metal reflector shield. The action is restricted to the ceiling, whence it is diffused all round. The alternating-current arc is not only less efficient in mean spherical candle-power per watt of electric power absorbed, but its distribution of light is disadvantageous. A further classification can be made between the arc lamps which have been worked off an alternating-current circuit for public lighting it is usual to make use of a rectifier, which rectifies the alternating current into a unidirectional one pulsating current. (2) Arc lamps are classified as divided and closed arcs. The enclosed arc can be made to burn for 200 hours with one pair of carbons, whereas open-arc lamps are usually only able to work 8, 16 or 32 hours without recarbonating, even when fitted with grooved or slotted carbons. Three forms are the focusing and non-focusing lamps. In the former the lower carbon is made to move up as the upper carbon moves down, and the arc is therefore maintained at the same level. This is advisable for arcs included in search light and lamp forms for lighthouses.

The carbons in large search-light lamps are usually employed. The self-regulating lamps may be classified into groups depending upon the nature of the regulating apparatus. In some cases the variation in tension is regulated only by a series coil, and in others only by a shunt coil. Examples of these are the familiar Gúicher and Brush cluch lamp, and some modern enclosed arc lamps; and of the latter, the Siemens "hant" lamp, and the Jackson "Mensing lamp. In series coil lamps the variation of the current is brought about by the carbon or coil being thrown in or out of action the carbon-moving mechanism; in shunt coil lamps the variation in voltage between the carbons is caused to effect the same changes. Other types of lamp involve the use both of shunt and series coils acting against each other. A further important point is that the mechanism may be thrown into or out of action and effects the necessary changes. In many cases the arc-lamp mechanism is provided with a dash-pot, or contrivance in which a piston moving nearly air-tight in a cylinder prevents sudden jerks in the motion of the mechanism and thus does away with the "hunting" or rapid up-and-down movements to which some varieties of clutch mechanism are liable. One very
efficient form is illustrated in the Thomson lamp and Brush-Vienna lamp. In this mechanism a shunt and series coil are placed side by side, and have iron cores suspended to the ends of a rocking arm held partly within them. Hence, according as the magnetic action of the shunt or series coil is prevalent, illumination is produced forwards or backwards. When the series coil is not in action the motion is free, and the upper carbon-holder slides down, or the lower one slips up, and starts the arc. The series coil comes into action with a greater or lesser force, but whether it be in action or not, the shunt coil then operates against the series coil, and between them the carbon is fed forwards as required. The control to be obtained is such that the arc shall never become so long as to flicker and become extinguished, when the carbons would come together again with a rush, but the feed should be smooth and steady, the position of the carbons responding quickly to each change in the current.

The introduction of enclosed arc lamps was a great improvement, in consequence of the arrangement of the carbon forming the arc and in the cost of labour for trimming. A well-known and widely used form of enclosed arc lamp is the Jandus lamp, which in large current form can be made to burn for two hundred hours without being re-carboned, each lamp is independent, but it is for forty hours, taking a current of two amperes at 100 volts. Such lamps in many cases conveniently replace large sizes of incandescent lamps, especially for shop lighting, as they give a whiter light. Great improvements have also been made in inclined carbon arc lamps. One reason for the relatively low efficiency of the usual vertical rod arrangement is that the crater can only radiate laterally, since owing to the position of the negative carbon no crater light is thrown anywhere. In one form, the arc is arranged for a downwards slanting position at a small angle like the letter V and the arc formed at the bottom tips, then the crater can emit downwards all the light it produces. It is found, however, that the arc of high-tension lamps is a suitable arc for a field lamp employed to keep the arc in position at the carbon tips. This method has been adopted in the Carbone arc, which, by the employment of inclined carbons, and a suitable electromagnet to keep the arc true, has achieved considerable success. The feature of the Carbone arc is the use of a relatively high voltage between the carbons, their potential difference being as much as 85 volts.

Arc lamps may be arranged either (i.) in series, (ii.) in parallel or (iii.) in series parallel. In the first case a number, say 20, may be traversed by the same current, in that case supplied at a pressure of 1000 volts. Each must have a magnetic cut-out, so that if the carbons stick together or remain apart the current to the other lamps is not interrupted, the function of such a cut-out being to close the main circuit immediately any one lamp ceases to pass current. Arc lamps worked in series are generally supplied with a current from a constant current dynamo, which maintains an invariable current of say 10 amperes, independently of the number of lamps on the external circuit. If the lamps, however, are worked in series off a constant potential circuit, such as one supplying at the same time incandescent lamps, provision must be made by which a resistance coil can be substituted for any one lamp removed or short-circuited. When lamps are worked in parallel, each lamp is independent, but it is necessary to add a resistance in series with the lamp. By special devices three lamps can be worked in series of 100 volt circuits. Alternating-current arc lamps can be worked off a high-tension circuit in parallel by providing each lamp with a small transformer. In some cases the alternating high-tension current is rectified and supplied as a unidirectional current to lamps in series. If single alternating-current lamps have to be worked off a 100 volt alternating-circuit, each lamp must have in series with it a choking coil or economy coil, to reduce the circuit pressure to that required for one lamp. Alternating-current lamps take a larger effective current, and work with a less effective or virtual carbon P.D., than continuous current arcs of the same wattage.

The cost of working public arc lamps is made up of several items. There is first the cost of supplying the necessary electric energy, then the cost of the carbons and the labour of re-carboning, and, lastly, an item due to depreciation and repairs of the lamps. An ordinary type of open 10 amperes arc lamp, burning carbons 15 and 9 mm. in diameter for the positive and negative, and working every night of the year from dusk to dawn, uses about 600 ft. of carbons per annum. If the positive carbon is 18 mm. and the negative 12 mm., the consumption of each size of carbon is about 70 ft. per 1000 hours of burning. It may be roughly stated that at the present prices of plain open arc-lamp carbons the cost is about 15s. per 1000 hours of burning; hence if such a lamp is burnt every night from dusk to midnight the annual cost in that respect is about £1 10s. The annual cost of labour per lamp for trimming is in Great Britain from £1 2s. to £3: hence, approximately speaking, the cost per annum of maintenance of a public arc lamp burning every night from dusk to midnight is about £4 2s. to £5, or perhaps £6, per annum, depreciation and repairs included. Since such a 10 amperes lamp uses half a Board of Trade unit of electric energy every hour, it will take 1000 Board of Trade units per annum, burning every night from dusk to midnight; and if this energy is supplied, say at 1½d. per unit, the annual cost of energy will be about £6, and the upkeep of the lamp, including carbons, labour for trimming and repairs, will be about £10 to £11 per annum. The cost for labour and carbons is considerably reduced by the employment of the enclosed arc lamp, but owing to the absorption of light produced by the inner enclosing globe, and the necessity for generally employing a second outer globe, there is a lower resultant candle-power per watt expended in the arc. Enclosed arc lamps are made to burn without attention for 200 hours, singly on 100 volt circuits, or two in series on 200 volt circuits, and in addition to the cost of carbons per hour being only about one-twentieth of that of the open arc, they have another advantage in the fact that there is a more uniform distribution of light on the road surface, because a greater proportion of light is thrown out horizontally. It has been found by experience that the ordinary type of open arc lamp with vertical carbons included in an opaque globe cannot compete in point of cost with modern improvements in gas lighting as a means of street illumination. The violet colour of the light and the sharp shadows, and particularly the non-illuminated area just beneath the lamp, are grave disadvantages. The high-pressure flame arc lamp with inclined chemically treated carbons has, however, put a different complexion on matters. Although the treated carbons cost more than the plain carbons, yet there is a great increase of emitted light, and a 10 amperes flame arc lamp supplied with electric energy at 1½d. per unit can be used for 1000 hours at an inclusive cost of about £5 to £6, the mean emitted illumination being at the rate of 4 c.p. per watt absorbed. In the Carbone arc lamp, the carbons are worked at an angle of 15° or 20° to each other and the arc is formed at the lower ends. If the potential difference of the carbons is low, say only 50-60 volts, the crater forms between the tips of the carbons and is therefore more or less hidden. If, however, the voltage is increased to 90-100 the true flame of the arc is longer and is curved, and the crater forms at the extreme tip of the carbons and throws all its light downwards. Hence results a far greater mean hemispherical candle power (M.H.S.C.P.) so that whereas a 10 amperes 60 volt open arc gives at most 1200 M.H.S.C.P., a Carbone 10 amperes 85 volt arc will give 2700 M.H.S.C.P. Better results still can be obtained with impregnated carbons. But the flame arcs with impregnated carbons cannot be enclosed, so the consumption of carbon is greater, and the carbons themselves are more costly, and leave a greater ash on burning; hence more trimming is required. They give a more pleasing effect for street lighting, and their golden yellow globe of light is more useful than the equal costily plain arc of the open type. This improvement in efficiency is, however, accompanied by some disadvantages. The flame arc is very sensitive to currents of air and therefore has to be shielded from draughts by putting it under an "economizer" or chamber of highly refractory material which surrounds the upper carbon, or both carbons are formed one a prepared carbon, the other one formed with inclined carbons. (For additional information on arc lamps see a paper by L. B. Marks and H. E. Clifford, Electrician, 1906, 57, p. 975.)

2. Incandescent Lamps.—Incandescent electric lighting, although not the first, is yet in one sense the most obvious method of utilizing electric energy for illumination. It was evolved from the early observed fact that a conductor is heated
when traversed by an electric current, and that if it has a high resistance and a high melting-point it may be rendered incandescent, and therefore become a source of light. Naturally every inventor who was acquainted with the employment of wires of refractory metals, such as platinum or alloys of platinum-iridium, &c., for the purpose of making an incandescent lamp. F. de Moleyns experimented in 1841, E. A. King and J. W. Starr in 1845, J. J. W. Watson in 1853, and W. E. Staite in 1848, but these inventors achieved no satisfactory result. Part of their want of success is attributable to the fact that the problem of the economical production of electric current by the dynamo machine had not then been solved. In 1878 T. A. Edison devised lamps in which a platinum wire was employed as the light-giving agent, carbon being made to adhere round it by pressure. Abandoning this, he next directed his attention to the construction of an "electric candle," consisting of a thin cylinder or rod formed of finely-divided metals, platinum, iridium, &c., mixed with refractory oxides, such as magnesia, or zirconia, lime, &c. This refractory body was placed in a closed vessel and heated by being traversed by an electric current. In a further improvement he proposed to use a block of refractory oxide, round which a bobbin of fine platinum or platinum-iridium wire was coiled. Every other inventor who worked at this branch of lighting science had followed nearly the same path of invention. Long before this date, however, the notion of employing carbon as a substance to be heated by the current had entered the minds of inventors; even in 1845 King had employed a small rod of plumbago as the substance to be heated. It was obvious, however, that carbon could only be so heated when in a space destitute of oxygen, and accordingly King placed his plumbago rod in a barometric vacuum. S. W. Konn in 1872, and S. A. Kosloff in 1875, followed in the same direction.

No real success attended the efforts of inventors until it was finally recognized, as the outcome of the work by J. W. Swan, T. A. Edison, and, in a lesser degree, St. G. Lane Fox and W. E. Sawyer and A. Man, that the conditions of success were as follow: First, the substance to be heated must be carbon in the form of a thin wire rod or thread, technically termed a filament; second, this must be supported and enclosed in a vessel formed entirely of glass; third, the vessel must be exhausted as perfectly as possible; and fourth, the current must be conveyed into and out of the carbon filament by means of platinum wires hermetically sealed through the glass.

One great difficulty was the production of the carbon filament. King and others had attempted to cut out a hexagonally shaped piece of carbon from a solid block; but Edison and Swan were the first to show that the proper solution of the difficulty was to carbonize an organic substance to which the necessary form had been given by the process of folding or rolling round carbon former and impregnating with an ordinary thread were originally employed, and even, according to Edison, a mixture of lampblack and tar rolled out into a fine wire and bent into a spiral. At one time Edison employed a filament of bamboo, carbonized after being bent into a horse-shoe shape. Swan used a material formed by treating ordinary crochet cotton-wool with dilute sulphuric acid, the "parchmented thread" thus produced being afterwards carbonized. In the modern incandescent lamp filament it is customary to prepare first of all a form of soluble cellulose. Carefully purified cotton-wool is dissolved in some solvent, such as a solution of zinc chloride, and the viscous material so formed is forced by hydraulic pressure through a die. The long thread thus obtained, when hardened, is a semi-transparent substance resembling cat-gut, and when carefully carbonized at a high temperature gives a very dense and elastic form of carbon filament. It is cut into appropriate lengths, which after being bent into horse-shoes, double-loops, or any other shape desired, are coiled or twisted, and then introduced into the plumbago crucibles, packed in with finely divided plumbago. The crucibles are then heated to a high temperature in an ordinary combustion or electric furnace, whereby the organic matter is destroyed and a skeleton of carbon remains. The highest temperature at which this carbonization is conducted, the denser is the resulting product. The filaments so prepared are sorted and measured, and short leading-in wires of platinum are attached to their ends by a carbon cement, or by a carbon-depositing process. They are then mounted in bulbs of lead glass having the same coefficient of expansion as platinum, through the walls of which, therefore, the platinum wires can be hermetically sealed. The bulbs pass into the exhausting-room, where they are exhausted by some form of mechanical or mercury pump. During this process an electric current is sent through the filament to heat it, in order to disengage the gases occluded in the carbon, and exhaustion must be so perfect that no luminous glow appears within the bulb when held in the hand and touched against one terminal of an induction coil in operation.

In the course of manufacture a process is generally applied to the carbon which is technically termed "treatment." The carbon filament is placed in a vessel surrounded by an atmosphere of hydrocarbon, such as coal gas or vapour of benzol. If current is then passed through the filament the hydrocarbon vapour is decomposed, and carbon is thrown down upon the filament in the form of a lustrous and dense deposit having an appearance like steel when seen under the microscope. This deposited carbon is not only much more dense than ordinary carbonized organic material, but it has a much lower specific electric resistance. An untreated carbon filament is generally termed the primary carbon, and a deposited carbon the secondary carbon. The greatest amount of deposit is at any places of high resistance in the primary carbon, and hence it tends to cover up or remedy the defects which may exist. The bright steel surface of a well-treatment is a desirable characteristic; if an untreated surface is exposed, it is not the result of treating; hence it does not require the expenditure of so much electric power to bring it to the same temperature, and probably on account of its greater density it ages much less rapidly.

Finally, the lamp is provided with a collar having two sole plates on it, to which the terminal wires are attached, or else the terminal wires are simply bent into two loops; in a third form, the Edison screw terminal, it is provided with a central metal plate, to which one end of the filament is connected, the other end being soldered to a screw collar. The collars and screws are formed of thin brass embedded in plaster of Paris, or in some material like vitrile or black glass (fig. 15). To put the lamp into connexion with the circuit provided for the current, it is inserted into the socket holder. Three of the principal types of holder in use are the bottom contact (B.C.) or Dornfeld socket, the Edison screw-collar socket and the Swan or loop socket. In the socket of C. Dornfeld (fig. 16, a and a') two spring pistons, in contact with the sides of the circuit, are fitted into the bottom of a short metallic tube having bayonet joint slots cut in the top. The brass collar on the lamp has two pins, by means of which a bayonet connexion is made between it and the socket; and when this is done, the spring pins are pressed against the sole plates on the lamp. In the Edison socket (fig. 16, b) a short metal tube with an insulating lining has on its interior a screw plate, which is in connexion with one wire of the circuit at the bottom of the tube, and insulated from the screw plate, is a central metal button, which is in connexion with the other side of the circuit. On screwing the lamp into the socket, the screw collar of the lamp and the boss or plate at the base of the lamp make contact with the corresponding parts of the socket, and complete the connexion. In some cases a form of switch is included in the socket, which is then termed the key-holder. For loop lamps the socket consists of an insulated block, which is held by the head of the key-block, and engages with the eyes of the lamp. This insulating block also carries some form of spiral spring or pair of spring loops, by means of which the spring pips are pressed against the socket, and the eyes kept tight by the hooks. This spring or Swan socket (fig. 16, c) is found useful in places where the lamps are subject to vibration, for in such cases the Edison screw collar cannot well be used, because the vibration loosens the contact of the lamp in the socket. The sockets may be fitted with appliances for holding ornamental shades or conical reflectors.
The incandescent filament being a very brilliant line of light, various devices are adopted for moderating its brilliancy and distributing the light. A simple method is to sand-blast the exterior of the bulb, whereby it acquires an appearance similar to that of ground glass, or the bare lamp may be enclosed in a suitable glass shade. Such shades, however, if made of opalescent or semi-opaque glass, absorb 40 to 60% of the light; hence various forms of dioptric shade have been invented, consisting of a clear glass screen with a ruled line such manner as to diffuse the light without any great absorption. Invention has been fertile in devising etched, coloured, opalescent, frosted and ornamental shades for decorative purposes, and for constructing special forms for use in lamps and factories for illuminating, where the globe containing the lamp must be air-tight. High candle-power lamps, 500, 1000 and upwards, are made by placing in one large glass globe numerous candle-power filaments arranged in parallel between two rings, which are connected with the main leading-in wires. When incandescent lamps are used for optical purposes it is necessary to compress the filament into a small space, bringing it into the focus of a lens or mirror. The filament is then coiled or crumpled up into a spiral or zigzag form. Such lamps are called focus lamps.

Incandescent lamps are technically divided into high and low voltage lamps, high and low efficiency lamps, standard and fancy lamps. The difference between high and low efficiency lamps is based upon the relation of the power absorbed by the lamp to the candle-power emitted. Every lamp when manufactured is marked with a certain figure, called the marked volts. This is understood to be the electromagnetic force in volts which must be applied to the lamp terminals to produce through the filament a current of such magnitude that the lamp will have a practically satisfactory life, and give in a horizontal direction a certain candle-power, which is also marked upon the glass. The numerical product of the current in amperes passing through the lamp, and the difference in potential of the terminals measured in volts, gives the total power taken up by the lamp in watts; and this number divided by the candle-power of the lamp (taking generally a horizontal direction) gives the watts per candle-power. This is an important figure, because it is determined by the temperature; it therefore determines the quality of the light emitted by the lamp, and also fixes the average duration of the filament when rendered incandescent by a current. Even in a good vacuum the filament is not permanent. Apart altogether from accidental defects, the carbon is slowly volatilized, and carbon molecules are also projected in straight lines from different portions of the filament. This process not only causes a change in the nature of the surface of the filament, but also a deposit of carbon on the exterior of the bulb when the glass is blackened and the candle-power of the lamp reduced. The volatilization increases very rapidly as the temperature rises. Hence at points of high resistance in the filament, more heat being generated, a higher temperature is attained, and the scattering of the carbon becomes very rapid; in such cases the filament is sooner or later cut through at the point of high resistance. In order that incandescent lighting may be practically possible, it is essential that the lamps shall have a certain average life, that is, duration; and this useful duration is fixed not merely by the possibility of passing a current through the lamp at all, but by the rate at which the candle-power diminishes. The decay of candle-power is called the ageing of the lamp, and the useful life of the lamp may be said to be that period of its existence before it has deteriorated to a point when it gives only 75% of its original candle-power. It is found that in practice carbon filament lamps, as at present made, if worked at a higher efficiency than $2 \frac{1}{2}$ watts per candle-power, exhibit a rapid deterioration in candle-power and an abbreviated life. Hence lamp manufacturers classify lamps into various classes, marked for use say at $2 \frac{1}{2}$, $3 \frac{1}{2}$ and 4 watts per candle. A $2 \frac{1}{2}$ watt per candle lamp would be called a high-efficiency lamp, and a 4 watt per candle lamp would be called a low-efficiency lamp. In ordinary circumstances the low-efficiency lamp would probably have a longer life, but its light would be less suitable for many purposes of illumination in which colour discrimination is required. The possibility of employing high-efficiency lamps depends greatly on the uniformity of the electric pressure of the supply. If the voltage is exceedingly uniform, then high-efficiency lamps can be satisfactorily employed; but they are not adapted for standing the variations in pressure which are liable to occur with public supply-stations, since, other things being equal, their filaments are less substantial. The classification into high and low voltage lamps is based upon the watts per candle-power corresponding to the marked volts. When incandescent lamps were first introduced, the ordinary working voltage was 50 or 100, but now a large number of public supply-stations furnish current to consumers at a pressure of 200 or 250 volts. This increase was necessitated by the enlarging area of supply in towns, and therefore the necessity for conveying through the same subterranean copper cables a large supply of electric energy without increasing the maximum current value and the size of the cables. This can only be done by employing a higher working electromotive force; hence arose a demand for incandescent lamps having marked volts of 200 and upwards, technically termed high-voltage lamps. The employment of higher pressures in public supply-stations has necessitated greater care in the selection of the lamp fittings, and in the manner of carrying out the wiring work. The advantages, however, of higher supply pressures, from the point of view of supply-stations, are undisputed. At the same time the consumer desired a lamp of a higher efficiency than the ordinary carbon filament lamp. The demand for this stimulated efforts to produce improved carbon lamps, and it was found that if the filament were exposed to a very high temperature, 3000° C. in an electric furnace, it became more refractory and was capable of burning in a lamp at an efficiency of 25 watts per c.p. Inventors also turned their attention to substances other than carbon which can be rendered incandescent by the electric current.

The luminous efficiency of any source of light, that is to say, the percentage of rays emitted which affect the eye as light compared with the total radiation, is dependent upon its temperature. In an ordinary oil lamp the luminous rays do not form much more than 3% of the total radiation. In the carbon-filament incandescent lamp, when worked at about 3 watts per candle, the luminous efficiency is about 5%; and in the arc lamp the radiation from the crater contains about 10 to 15% of eye-affecting radiation. The temperature of a carbon filament working at about 3 watts per candle is not far from the melting-point of platinum, that is to say, is nearly 1775° C. If it is worked at a higher efficiency, the candle-power, the temperature rises rapidly, and at the same time the volatilization and molecular scattering of the carbon is rapidly increased, so that the average duration of the lamp is very much shortened. An improvement, therefore, in the efficiency of the incandescent lamp can only be obtained by finding some substance which will endure heating to a higher temperature than the carbon filament. Inventors turned their attention many years ago, with this aim, to the refractory oxides and similar substances. Paul Jablchickoff in 1877 described and made a lamp consisting of a piece of kaolin, which was brought to a state of incandescence first by passing over it an electric spark, and afterwards maintained in a state of incandescence by a current of lower electromotive force. Lane Fox and Edison, in 1878, proposed to employ platinum wires covered with films of lime, magnesia, steatite, or with the rarer oxides, zirconia, thoria, &c.; and Lane Fox, in 1879, suggested as an incandescent substance a mixture of particles of carbon with the earthy oxides. These earthy oxides—magnesia, lime and the oxides of the rare earths, such as thoria, zirconia, erbia, yttria, &c.—possess the peculiarity that at ordinary temperatures they are practically non-conductors, but at very high temperatures their resistance at a certain point rapidly falls, and they become fairly good conductors. Hence if they can once be brought into a state of incandescence a current can pass through them and maintain them in that state. But at this temperature they give up oxygen to carbon; hence no mixtures of earthy oxides with carbon are permanent when heated, and failure
has attended all attempts to use a carbon filament covered with such substances as thoria, zirconia or other of the rare oxides.

H. W. Nernst in 1897, however, patented an incandescent lamp in which the incandescent body consists entirely of a slender rod or filament of magnesia. If such a rod is heat by the oxygen-blowpipe to a high temperature it becomes conductive, and can then be maintained in an intensely luminous condition by passing a current through it after the flame is withdrawn. Nernst found that by mixing together, in suitable proportions, oxides of the rare earths, he was able to prepare a material which can be formed into slender rods and threads, and which is rendered sufficiently conductive to pass a current with an electromotive force as low as 100 volts, merely by being heated for a few moments with a spirit lamp, or even by the radiation from a neighbouring platinum spiral brought to a state of incandescence.

The Nernst lamp, therefore (fig. 17), consists of a slender rod of the mixed oxides attached to platinum wires by an oxide paste.

Oxide filaments of this description are not enclosed in an exhausted glass vessel, and they can be brought, without risk of destruction, to a temperature considerably higher than a carbon filament; hence the lamp has a higher luminous efficiency. The material now used for the oxide rod or "glower" of Nernst lamps is a mixture of zirconia and yttria, made into a paste and sprinkled or pressed into slender rods. This material is non-conductive when cold, but when slowly heated it becomes conductive and then falls considerably in resistance. The glower, which is straight in some types of the lamp but curved in others, is generally about 3 or 4 cm. long and 1 or 2 mm. in diameter. It is held between terminals, and close to or about it, but not touching it, is a loose coil of platinum wire, also covered with oxide and called the "heater" (fig. 18). In series with it is a spiral of iron wire, enclosed in a bulb full of hydrogen, the resistance of which is called the "ballast resistance." The socket also contains a switch controlled by an electromagnet. When the current is first switched on it passes through the heater coil which, becoming incandescent, by radiation heats the glower until it becomes conductive. The glower then takes current, becoming itself brilliantly incandescent, and the electromagnet becomes energized switches the heater coil out of circuit. The iron ballast wire increases in resistance with increase of current, and so operates to keep the total current through the glower constant in spite of small variations of circuit voltage. The disadvantages of the lamp are (1) that it does not light immediately after the current is switched on and is therefore not convenient for domestic use; (2) that it cannot be made in small light units such as 5 c.p.; (3) that the socket and fixture are large and more complicated than for the carbon filament lamp. But owing to the higher temperature the light is whiter than that of the carbon glow lamp, and the efficiency or candle power per unit of the glower constant in spite of the lower temperature. Patents have also been taken out for lamps made with filaments of such insubfluous metals as tungsten and molybdenum, and Siemens and Halske, Sanders and others, have protected methods for employing zirconium and other rare metals. According to the patents of Sanders (German patents Nos. 133501, 137568, 137569) zirconium filaments are manufactured from the hydrogen or nitrogen compounds of the rare earths by the aid of some organic binding material. H. Kuzel of Vienna (British Patent No. 28154 of 1904) described methods of making metallic filaments from any metal. He employs the metals in a colloid condition, either as hydrosol, organosol, gel, or colloidal suspension. The metals are thus obtained in a gelatinous form, and can be sprayed into filaments which are dried and reduced to the metallic form by passing an electric current through them (Electrician, 57, 804). This process has a wide field of application, and enables the most refractory and insubfluous metals to be obtained in a metallic wire form. The zirconium and tungsten wire lamps are equal to or surpass the tantalum lamp in efficiency.
and are capable of giving light, with a useful commercial life, at an efficiency of about one watt per candle. Lamps called osram lamps, with filaments composed of an alloy of osmium and tungsten ( wolfram), can be used with a life of 1000 hours when run at an efficiency of about 1.5 watts per candle.

Tungsten lamps are made by the processes of Just and Hanman (German patent No. 154262 of 1903) and of Kuzel, and at a useful life of 1000 hours, with a falling off in light-giving power of only 10-15%, they have been found to work at an efficiency of one to 1.25 watts per c.p. Further collected information on modern metallic wire lamps and the patent literature thereof will be found in an article in the Engineer for December 7, 1906.

Mention should also be made of the Helion filament glow lamp in which the glower is composed largely of silicon, a carbon filament being used as a base. This filament is said to have a number of interesting qualities and an efficiency of about 1 watt per candle (see the Electrician, 1907, 58, p. 657).

The mercury vapour lamps of P. Cooper-Hewitt, C. O. Bastian and others have a certain field of usefulness. If a glass tube, highly exhausted, contains mercury vapour and a mercury cathode and iron anode, a current can be passed through it under high electromotive force and will then be maintained when the voltage is reduced.

The mercury vapour is rendered incandescent and glows with a brilliant greenish light which is highly actinic, but practically monochromatic, and is therefore not suitable for general illumination because it does not reveal objects in their daylight colours. It is, however, an exceedingly economical source of light. A 3-ampere Cooper-Hewitt mercury lamp has an efficiency of 0.15 to 0.33 watts per candle, or practically the same as an arc lamp, and will burn for several thousand hours. A similar lamp with mercury vapour included in a tube of white glass specially transparent to ultra-violet light (prepared by Schott & Co. of Jena) seems likely to replace the Finsen arc lamp in the treatment of lupus. Many attempts have been made to render the mercury vapour lamp polychromatic by the use of amalgams of zinc, sodium and bismuth in place of pure mercury for the negative electrode.

An important matter in connexion with glow lamps is their photometry. The arrangement most suitable for the photometry and testing of incandescent lamps is a gallery or room large enough to be occupied by several workers, the walls being painted deep black. The photometer, preferably one of the Lummeter-Brothum form, is set up on a gallery or bench. On one side of it must be fixed a working standard, which as first suggested by Fleming is preferably a large bulb incandescent lamp with a specially "aged" filament. Its candle-power can be compared, at regular intervals and known voltages, with that of some accepted flame standard, such as the 10 candle pentane lamp of Vernon Harcourt. In a lamp factory or electrical laboratory it is convenient to have a number of such large bulb standard lamps. This working standard should be maintained at a fixed distance on one side of the photometer, such that when worked at a standard voltage it creates an illumination of one candle-foot on one side of the photometer disk. The incandescent lamp to be examined is then placed on the other side of the photometer disk on a traveling carriage, so that it can be moved to and fro. Arrangements must be made to measure the current and the voltage of this lamp under test, and this is most accurately accomplished by employing a potentiometer (qa). The holder which carries the lamp should allow the lamp to be held with its axis in any required position; in making normal measurements the lamp should have its axis vertical, the filament being so situated that none of the turns or loops overlies another as seen from the photometer disk. Observations can then be made of the candle-power corresponding to different currents and voltages.

The candle-power of the lamp varies with the other variables in accordance with exponential laws of the following kind:

If A is the current in amperes through the lamp, V the voltage or terminal potential difference, W the power absorbed in watts, c.p.

the maximum candle-power, and a, b, c, etc., constants, it has been found that A and c.p. are connected by an exponential law such that

\[ \text{c.p.} = A e^{bV} \]

For carbon filament lamps \( x \) is a number lying between 5 and 6, generally equal to 5.5 or 5.6. It has also been found that \( c.p. = bV^5 \) nearly, and that

\[ \text{c.p.} = e^{cV} \]

where \( c \) is some other constant, and for carbon filaments \( y \) is a number nearly equal to 6. It is obvious that if the candle-power of the lamp varies very nearly as the 6th power of the current and of the voltage, the candle-power must vary as the cube of the voltage.

Sir W. de W. Abney and E. R. Festing have also given a formula connecting candle-power and watts equivalent to \( c.p. = (W - d)^5 \) where \( d \) is a constant.

In the case of the tantalum lamp the exponent \( x \) has a value near to 6, but the exponent \( y \) is a number near to 4, and the same for the osmium filament. Hence for these metallic glowers a certain percentage variation of voltage does not cause so great a variation in candle-power as in the case of the carbon lamp.

Curves delineating the relation of these variables for any incandescent lamp are called its characteristic-curves. The life or average duration is a function of W/c.p., or of the watts per candle-power, and of the voltage at which the lamp is worked. It follows from the above relation that the watts per candle-power vary inversely as the fourth power of the voltage.

From limited observations it seems that the average life of a carbon-filament lamp varies with the fifth or sixth power of the watts per candle-power. If \( V \) is the voltage at which the lamp is worked and \( L \) its average life, then \( L \) varies roughly as the twenty-fifth power of the reciprocal of the voltage, or

\[ L \propto V^{-25} \]

A closer approximation to experience is given by the formula

\[ \log_{10}L = 13.5 - \frac{9}{10}V \]

(See J. A. Fleming, "Characteristic Curves of Incandescent Lamps," Phil. Mag. May 1885.)

All forms of incandescent or glow lamps are found to deteriorate in light-giving power with use. In the case of carbon filaments this is due to two causes. As already explained, carbon is scattered from the filament and deposited upon the glass, and changes also take place in the filament which cause it to become reduced in temperature, even when subjected to the same terminal voltage. In many lamps it is found that the first effect of running the lamp is slightly to increase its candle-power, even although the voltage be kept constant; this is the result of a small decrease in the resistance of the filament. The heating to which it is subjected slightly reduces the deposit on the bulb, and this, since the vacuum is not perfect, has the effect of making the filament lower in resistance, and therefore it takes more current at a constant voltage. The greater part, however, of the subsequent decay in candle-power is due to the deposit of carbon upon the bulb, as shown by the fact that if the filament is taken out of the bulb and put into a new clean bulb the candle-power in the majority of cases returns to its original value. For every lamp there is a certain point in its career which may be called the "smashing-point," when the candle-power falls below a certain percentage of the original value, and when it is advantageous to replace it by a new one.

Variations of pressure in the electric supply exercise a prejudicial effect upon the light-giving qualities of incandescent lamps. If glow lamps, nominally of 100 volts, are supplied from a public lighting-station, in those lamps of which the current varies between 90 and 70 we, their life will be greatly abbreviated, and they will become blackened much sooner than would be the case if the pressure were perfectly constant. Since the candle-power of the lamp varies very nearly as the fifth or sixth power of the voltage, it follows that a variation of 10% in the electromotive force creates a variation of nearly 50% in the candle-power. Thus a 16 candle-power glow lamp, marked for use at 100 volts, was found on test to give the following candle-powers at voltages varying between 90 and 105: At 105 volts it gave 22.8 c.p.; at 100 volts, 16.7 c.p.; at 95 volts, 12.2 c.p.; and at 90 volts, 8.7 c.p. Thus a variation of 25% in the candle-power was caused by a variation in voltage of only 5%. The same kind of variation in working voltage exercises also a marked effect upon the average duration of the lamp.
figures show the results of some tests on typical 3-1/2 watt lamps run at voltages above the normal, taking the average life when worked at the marked volts (namely, 100) as 1000 hours:

</table>

The gradual increase in watts per candle-power shown by this table does not imply necessarily an increase in the total power taken by the lamp, but is the consequence of the decay in candle-power produced by the blackening of the lamp. Therefore, to estimate the value of an incandescent lamp the user must take into account not merely the price of the lamp and the initial watts per candle-power, but the rate of decay of the lamp.

The scattering of carbon from the filament to the glass bulb produces interesting physical effects, which have been studied by T. A. Edison, W. H. Preece and J. A. Fleming.

If an ordinary carbon-filament glow lamp a platinum plate is sealed, not connected to the filament but attached to a third terminal, it is found that when the lamp is operated with continuous current a galvanometer connected in between the middle plate and the positive terminal of the lamp indicates a current, but not when connected in between the negative terminal of the lamp and the middle plate. If the middle plate is placed between the legs of a horse-shoe-shaped filament, it becomes blackened most quickly on the side facing the negative pole. This effect, commonly called the Edison effect, is connected with an electric discharge and convection of carbon which takes place between the two extreme ends of the filament, and, as experiment seems to show, consists in the conveyance of an electric charge, either by carbon molecules or by bodies smaller than molecules. There is, however, an electric discharge between the ends of the filament, which rapidly increases with the temperature of the filament and the terminal voltage; hence one of the difficulties of manufacturing high-voltage glow lamps, that is to say, glow lamps for use on circuits having an electromotive force of 300 volts and upwards, is the discharge from one leg of the filament to the other.

A brief allusion may be made to the mode of use of incandescent lamps for interior and private lighting. At the present time, hardly any other method of distribution is adopted than that of an arrangement in parallel; that is to say, each lamp on the circuit has one terminal connected to a wire which finally terminates at one pole of the generator, and its other terminal connected to a wire leading to the other pole. The lamps themselves are attached to a very variety of ornamental fitting, or in many cases suspended by a simple pendant, consisting of an insulated double flexible wire attached at its upper end to a ceiling rose, and carrying at the lower end a shade and socket in which the lamp is placed. Lamps thus hung head downwards are disadvantageously used because their end-on candle-power is not generally more than 60% of their maximum candle-power. In interior lighting one of the great objects to be attained is uniformity of illumination with avoidance of harsh shadows. This can only be achieved by a proper distribution of the lamps. It is impossible to give any hard and fast rules as to what number must be employed in the illumination of any room, as a great deal depends upon the nature of the reflecting surfaces, such as the walls, ceilings, &c. As a rough guide, it may be stated that for every 100 sq. ft. of floor surface one 16 candle-power lamp placed about 8 ft. above, the floor will give a dull illumination, two will give a good illumination and four will give a brilliant illumination.

We generally judge of the nature of the illumination in a room by our ability to read comfortably in any position. That this may be done, the horizontal illumination on the book should not be less than one candle-foot. The following table shows approximately the illuminations in candle-feet, in various situations, derived from actual experiments:

- In a well-lighted room on the floor or tables, 10 to 20 c.f.
- On a theatre stage, 30 to 40 c.f.
- On a railway platform, 50 to 60 c.f.
- In a picture gallery, 60 to 35 c.f.
- The mean daylight in the May in the interior of a room, 30 to 40 c.f.
- In full sunlight, 7000 to 10,000 c.f.
- In full moonlight, 1/100th to 1/100th c.f.

From an artistic point of view, one of the worst methods of lighting a room is by pendant lamps, collected in single centres in large numbers. The lights ought to be distributed in different portions of the room, and so shadoned that the light is reflected only by reflecting foil-surrounding objects. Ornamental effects are frequently produced by means of candle lamps in which a small incandescent lamp, imitating the flame of a candle, is placed upon a white porcelain tube as a holder, and these small units are distributed and arranged in electroliers and brackets. For details as to the various modes of placing conducting wires in houses, and the various precautions for safe usage, the reader is referred to the article Electricity Supply.

In the case of low voltage metallic filament lamps when the supply is by alternating current there is no difficulty in reducing the service voltage to any lower value by means of a transformer. In the case of direct current the only method available for working such low voltage lamps off higher supply voltages is to arrange the lamps in series.

Additional information on the subjects treated above may be found in the following books and original papers:

- S. P. Thompson, The Arc Light, Cantor Lectures, Society of Arts;
- J. A. Fleming, Electric Lamps and Electric Lighting (London, 1899);

Commercial Aspects.—The cost of supplying electricity depends more upon the rate of supply than upon the quantity supplied; or, as John Hopkinson put it, "the cost of supplying electricity for 1000 lamps for ten hours is very much less than ten times the cost of supplying the same number of lamps for one hour." Efforts have therefore been made to devise a system of charge which shall in each case bear some relation to the cost of the service. Consumers vary largely both in respect to the quantity and to the period of their demands, but the cost of supplying any one of them with a given amount of electricity is chiefly governed by the amount of his maximum demand at any one time. The reason for this is that it is not generally found expedient to store electricity in large quantities. Electricity supply works generate the electricity for the most part at the moment it is used by the consumer. Electric lamps are normally in use on an average for only about four hours per day, and therefore the plant and organization, if employed for a lighting load only, are idle and unremunerative for about 20 hours out of the 24. It is necessary to have in readiness machinery capable of supplying the maximum required by all the consumers at any hour, and this accounts for a very large proportion of the total cost. The cost of raw material, viz. coal, water and stores consumed in the generation of electricity sold, forms relatively only a small part of the total cost, the major part of which is made up of the fixed charges attributable to the time during which the works are unproductive. This makes it very desirable to secure demands possessing high "peak" and "diversity" factors. The correct way to charge for electricity is to give liberal rebates to those consumers who make prolonged and regular use of the plant, that is to say, the lower the "peak" demand and the more continuous the consumption, the better should be the discount. The consumer must be discouraged from making sudden large demands on the plant, and must be encouraged, while not reducing his total consumption, to spread his use of the plant over a large number of hours during the year. Mr Arthur Wright has devised a tariff which gives effect to this principle. The system necessitates the use of a special indicator—not to measure the quantity of electricity consumed, which is done by the ordinary meter—but to show the maximum amount of current taken by the consumer at any one time during the period for which he is charged. In effect it shows the proportion of plant which has had to be kept on hand for its use. If the indicator shows that ten lamps are the greatest number which the consumer has turned on simultaneously, then he gets a large discount on all the current which his ordinary meter would indicate, and this would be taken beyond the equivalent of one hour's daily use of those ten lamps. Generally the rate charged under this system is 7d. per unit for the equivalent of one hour's daily use of the maximum demand and 1d. per unit for all surplus. It is on this principle that it pays to supply current for tramway and other purposes at a price which prima facie is below the cost of production; it is only apparently so in comparison with the cost of producing electricity for lighting purposes. In the case of tramways the electricity is required for 15 or 16 hours per day. Electricity for a single lamp would cost on the basis of this "maximum-demand-indicator" system for 15 hours per day only 1 8d. per unit. In some cases a system of further discounts to very large consumers is combined with the Wright system. Some undertakers have abandoned the Wright system in favour of average flat rates, but this does not imply any failure of the Wright system; on the contrary, the system, having served to establish the most economical consumption of electricity, has demonstrated the average rate at which the undertakers are able to give the supply at a fair profit, and the proportion of possible new customers being small the undertakers find it a simplification to dispense with the maximum demand indicator. But in some cases a mistake has been made by offering the unprofitable early-closing consumers the option of obtaining electricity at a flat rate much lower than their load-factor would warrant and below cost price. The effect of this is to nullify the Wright system of charging, for a consumer will not elect to pay for his electricity on the Wright system if he can obtain a lower rate by means of a flat rate system. Thus the long-hour profitable consumer is made to pay a much higher price than he need be charged, in order that the unprofitable short-hour consumer may be retained and be made actually still more unprofitable. It is not improbable that ultimately the supply will be charged for on the basis of a rate determined by the size and character of the consumer's premises, or the number and dimensions of the electrical points, much in the same way as water is charged for by a water rate determined by the rent of the consumer's house and the number of water taps.

Most new houses within an electricity supply area are wired for electricity during construction, and in several towns means have to be taken to encourage small shopkeepers and tenants of small houses to use electricity by removing the obstacle of the first outlay on wiring. The cost of wiring may be taken at 15s. to £2 per lamp installed including all necessary wire, switches, fuses, lamps, holders, casing, but not electroliers or shades. Many undertakers carry out wiring on the easy payment or hire-purchase system. Parliament has sanctioned the adoption of these systems by some local authorities and even authorized them to do the work by direct employment of labour. The usual arrangement is to make an additional charge of 3½ per unit on all current used, with a minimum payment of 1s. per 8 c.p. lamp, consumers having the option of purchasing the installation at any time on specified conditions. The consumer has to enter into an agreement, and if he is only a tenant the landlord has to sign a memorandum to the effect that the wiring and fittings belong to the supply undertakers. Several undertakers have adopted a system of maintenance and renewal of lamps, and at least one local authority undertakes to supply consumers with lamps free of charge.

There is still considerable scope for increasing the business of electricity supply by judicious advertising and other methods. Comparisons of the kilowatt hour consumption per capita in various towns show that where an energetic policy has been pursued the profits have improved by reason of additional output combined with increased load factor. The average number of equivalent 8 c.p. lamps connected per capita in the average of English towns is about 1½. The average number of units consumed per capita per annum is about 23, and the average income per capita per annum is about 5s. In a number of American cities 20s. per capita per annum is obtained. In the United States a co-operative electrical development association canvasses both the general public and the electrical authorities and contractors, and the spirit underlying the work is to advertise the merits of electricity—not any particular company or interest. Their efforts are directed to securing new consumers and stimulating the increased and more varied use of electricity among actual consumers.

All supply undertakers are anxious to develop the consumption of electricity for power purposes even more than for lighting, but the first cost of installing electric motors is a deterrent to the adoption of electricity in small factories and shops, and most undertakers are therefore prepared to let out motors, &c., on hire or purchase on varying terms according to circumstances.

A board of trade unit will supply one 8 c.p. carbon lamp of 30 hours or 30 such lamps for one hour. In average use an incandescent lamp will last about 800 hours, which is equal to about 12 months normal use; a good lamp will frequently last more than double this time before it breaks down.
A large number of towns have adopted electricity for street lighting. Frank Bailey has furnished particulars of photometric tests which he has made on new and old street lamps in the city of London. From these tests the following comparative figures are deduced:

Apart from cheaper methods of generation there are two main sources of economy in electric lighting. One is the improved arrangement and use of electrical installations, and the other is the employment of lamps of higher efficiency. As regards the first, increased attention has been given to the position, candle-power and shading of electric lamps so as to give the most effective illumination in varying circumstances and to avoid excess of light. The ease with which electric lamps may be switched on and off from a distance lends itself to arrangements whereby current may be saved by switching off lights not in use and by controlling the number of lamps required to be alight at one time on an electrician. Appreciable economies are brought about by the scientific disposition of lights and the avoidance of waste in use. As regards the other source of economy, the Nernst, the talantum, the osram, and the metallized carbon filament lamp, although costing more in the first instance than carbon lamps, have become popular owing to their economy in current consumption. Where adopted largely they have had a distinct effect in reducing the rate of increase of output from supply undertakings, but their use has been generally encouraged as tending towards the greater popularity of electric light and an ultimately wider demand. Mercury vapour lamps for indoor and outdoor lighting have also proved their high efficiency, and the use of flame arc lamps has greatly increased the cheapness of outdoor electric lighting.

The existence of a "daylight load" tends to reduce the all-round cost of generating and distributing electricity. This daylight load is partly supplied by power for industrial purposes and partly by the demand for electricity in many domestic operations. The use of electric heating and cooking apparatus (including radiators, ovens, grills, chafing dishes, hot plates, kettles, flat-irons, curling irons, &c.) has greatly developed, and provides a load which extends intermittently throughout the greater part of the twenty-four hours. Electric fans for home ventilation are also used, and in the domestic operations where a small amount of power is required (as in driving sewing machines, boot cleaners, washing machines, mangles, knife cleaners, "vacuum" cleaners, &c.) the electric motor is being largely adopted. The trend of affairs points to a time when the total demand from such domestic sources will greatly exceed the demand for lighting only. The usual charges for current to be used in domestic heating or power operations vary from 1d. to 2d. per unit. As the demand increases the charges will undergo reduction, and will there also be a reflex action in bringing down the cost of electricity for lighting owing to the improved load factor resulting from an increase in the day demand. In the cooking and heating and motor departments also there has been improvement in the efficiency of the apparatus, and its economy is enhanced by the fact that current may be switched on and off as required.

The Board of Trade are now prepared to receive electric measuring instruments for examination or testing at their electrical standardizing laboratory, where they have a battery power admitting of a maximum current of 700 amperes to be dealt with. The London county council and some other corporations are prepared upon requisition to appoint inspectors to test meters on consumers' premises.

All supply undertakers now issue rules and regulations for the efficient wiring of electric installations. The rules and regulations issued by the institution of electrical engineers have been accepted by many local authorities and companies, and also by many of the fire insurance companies. The Phoenix fire office rules were the first to be drawn up, and are adopted by many of the fire offices, but some other leading insurance offices have their own rules under which risks are accepted without extra premium. In the opinion of the insurance companies "the electric light is the most satisfactory and is preferable to any others when the installation has been thoroughly well put up." Regulations have also been issued by the London county council in regard to Switzerland, &c., by the national board of fire underwriters of America (known as the "National Electrical Code"), by the fire underwriters association of Victoria (Commonwealth of Australia), by the Calcutta fire insurance agents association and under the Canadian Electric Light Inspection Act. In Germany rules have been issued by the Verband Deutscher Elektrotechniker and by the union private fire insurance companies of Germany. In Switzerland and by the Association Suisse des electriciens, in Austria by the Elektrotechnischer Verein of Vienna, in France by ministerial decree and by the syndicat professionnel des industries electriques. (For reprints of these regulations see Electrical Trades Directory.)

LIGHTNING, the visible flash that accompanies an electric discharge in the sky. In certain electrical conditions of the atmosphere a cloud becomes highly charged by the coalescence of drops of vapour. A large drop formed by the fusion of many smaller ones contains the same amount of electricity upon a smaller superficial area, and the electric potential of each drop, and of the whole cloud, rises. When the cloud passes near another cloud stratum or near a hilltop, tower or tree, a discharge takes place from the cloud in the form of lightning. The discharge sometimes takes place from the earth to the cloud, or from a lower to a higher stratum, and sometimes from conductors silently. Rain discharges the electricity quietly to earth, and lightning frequently ceases with rain (see ATMOSPHERIC ELECTRICITY).

LIGHTNING CONDUCTOR, or LIGHTNING Rod (Franklin), the name usually given to apparatus designed to protect buildings or ships from the destructive effects of lightning (Fr. paralumener, Ger. Blitzeableiter). The upper regions of the atmosphere being at a different electrical potential from the earth, the thick dense clouds which are the usual prelude to a thunder storm serve to conduct the electricity of the upper air down towards the earth, and an electrical discharge takes place across the air space when the pressure is sufficient. Lightning discharges are in general extinguished by their passage from the clouds to the earth, the A and the B flashes. The A flash is of the simple type which arises when an electrically charged cloud approaches the earth without an intermediate cloud intervening. In the second type B, where another cloud intervenes between the cloud carrying the primary charge and the earth, the two clouds practically form a condenser; and when a discharge from the first takes place into the second the free charge on the earth side of the lower cloud is suddenly relieved, and the disruptive discharge
from the latter to earth takes such an erratic course that according to the Lightning Research Committee "no series of lightning conductors of the hitherto recognized type suffice to protect the building." In Germany two kinds of lightning stroke have been recognized, one as "zündenden" (causing fire), analogous to the B flash, the other as "kalten" (not causing fire), the ordinary A discharge. The destructive effect of the former was noticed in 1884 by A. Parnell, who quoted instances of damage due to mechanical force, which he stated in many cases took place in a more or less upward direction.

The object of erecting a number of pointed rods to form a lightning conductor is to produce a glow or brush discharge and thus neutralize or relieve the tension of the thunder-cloud. This, if the latter is of the A type, can be successfully accomplished, but sometimes the lightning flash takes place so suddenly that it cannot be prevented, however great the number of points provided, there being such a store of energy in the descending cloud that they are unable to ward off the shock. A B flash may ignore the points and strike some metal work in the vicinity; to avoid damage to the structure this must also be connected to the conductors. A single air terminal is of no more use than an inscribed sign-board; besides multiplying the number of points in such a manner as to provide the conductors, the system of pipes and gutters on a roof must be imitated; although a single rain-water pipe would be sufficient to deal with a summer shower, in practice pipes are used in sufficient number to carry off the greatest storm.

**Protected Area.**—According to Lodge "there is no space near a rod which can be definitely styled an area of protection, for it is possible to receive violent sparks and shocks from the conductor itself, not to speak of the innumerable secondary discharges that are liable to occur in the wake of the main flash." The report of the Lightning Research Committee contains many examples of buildings struck in the so-called "protected area."

**Material for Conductors.**—Franklin's original rods (1752) were made of iron, and this metal is still employed throughout the continent of Europe and in the United States. British architects, who objected to the unsightliness of the rods, eventually specified copper tape, which is generally run round the shank angles of a building, and used in such a manner as to increase the chances of the lightning being diverted from the conductor. The popular idea is that to secure the greatest protection a rod of the largest area should be erected, whereas a single large conductor is far inferior to a number of smaller ones and copper as a material is not so suitable for the purpose as iron. A copper rod allows the discharge to pass too quickly and produces a violent shock, whereas iron offers more impedence and allows the flash to leak away by damping down the oscillations. Thus there is less chance of a side flash from an iron than from a copper conductor.

**Causes of Failure.**—A number of failures of conductors were noticed in the 1905 report of the Lightning Research Committee. One cause was the insufficient number of conductors and earth connexions; another was the absence of any system for connecting the metalic portion of the buildings to the conductors. In some cases the main stroke was received, but damage occurred by side-flash to isolated parts of the roof. There were several examples of large metallic surfaces being charged with electricity, the greater part of which was safely discharged from the building and not into the main building, such as a speaking-tube or electric bell wires, to cause damage. In one instance a flash struck the building at two points simultaneously; one portion followed the conductor, but the other went to earth jumping from a small finial to a greenhouse 30 ft. below.

**Construction of Conductors.**—The general conclusions of the Lightning Research Committee agree with the independent reports of similar investigators in Germany, Hungary and Holland. The following is a summary of the suggestions made:

The conductors may be of copper, or of soft iron protected by galvanizing or coated with lead. A number of paths to earth must be provided; well-jointed rain-water pipes may be utilized.

Every chimney stack or other prominence should have an air terminal. Conductors should run in the most direct manner from air to earth, and be kept away from the walls by holdfasts (fig. 1), in the manner shown by A (fig. 2); the usual method is seen in B (fig. 2), where the tape follows the contour of the building and causes side flash. A building with a long roof should also be fitted with a horizontal conductor along the ridge, and to this aigrettes (fig. 3) should be attached; a simpler method is to support the cables by holdfasts armed with a spike (fig. 4). Joints must be held together mechanically as well as electrically, and should be protected from the action of the air. At Westminster Abbey the cables are spiked and inserted in a box which is filled with lead run in when molten.

**Earth Connexion.**—A copper plate not less than 3 sq. ft. in area may be used as an earth connexion, if buried in permanently damp earth. Instead of a plate there are advantages in using the tubular earth shown in fig. 5. The cable packed in carbon descends to the bottom of the perforated tube which is driven into the ground, a connexion being made to the nearest rain-water pipe to secure the necessary moisture. No further attention is required. Plate earths should be tested every year. The number of earths depends on the area of the building, but at least two should be provided. Insulators on the conductor are of no advantage, and it is useless to gild or otherwise protect the points of the air-terminals. As heated air offers a good path for lightning (which is the reason why the kitchen-chimney is often selected by the discharge), a number of points should be fixed to high chimneys and there should be at least two conductors to earth. All roof metals, such as finials, flashings, rain-water gutters, ventilating pipes, cowls and stove pipes, should be connected to the system of conductors. The efficiency of the installation depends on the interconnexion of all metallic parts, also on the quality of the earth connexions. In the case of magazines used for explosives, it is questionable whether the usual plan of erecting rods at the sides of the buildings is efficient. The only way to ensure safety is to enclose the magazine in iron; the
LIGHTS, CEREMONIAL USE OF

next best is to arrange the conductors so that they surround it like a bird cage.

Bibliography.—The literature, although extensive, contains so many descriptions of ludicrous devices, that the student, after reading Benjamin Franklin's Experiments and Observations on Electricity made at Philadelphia (1751), and his address at the Lightning Rod Conference of December 1881. In the latter work there are abstracts of many valuable papers, especially the reports made to the French Academy, among others by Coulomb, Laplace, and Arago. In 1876 J. Clerk Maxwell read a paper before the British Association in which he brought forward the idea (based on Faraday's experiments) of protecting a building from the effects of lightning by surrounding it with circular or other forms of conductor. It was not, however, until the Bath meeting of the British Association in 1888 that the subject was fully discussed by the physical and engineering sections. Sir Oliver Lodge showed the utility of single conductors, and advised the interchange of the mechanical and electrical charges. Among the conductors buried in the earth. The action of lightning flashes was also demonstrated by him in lectures delivered before the Society of Arts (1886). The Clerk Maxwell system was adopted to a large extent in Germany, and in July 1901 a sub-committee of the Berlin Electro-technical Association was formed, which published rules. In 1900 a paper entitled "The Protection of Public Buildings from Lighting" by Sir George Cayley, G. H. Hedges (Hons. Sec.), was published, in April 1905. An illustrated supplement compiled by K. Hedges and entitled Modern Lighting Conductors (1905), contains particulars of the independent reports of the German committee, and the Dutch Academy of Science, and the Royal Joseph university, Budapest. A description is also given of the author's modified Clerk Maxwell system, in which the metal work of the roofs of a building form the upper part, the rain-water pipes taking the place of the usual lightning-rods. See also Sir Oliver Lodge, Lightning Conductors (London, 1902).

LIG\(\text{h}^{}\)TS, CEREMONIAL USE OF. The ceremonial use of lights in the Christian Church, with which this article is mainly concerned, probably has a double origin: in a very natural symbolism, and in the adaptation of certain pagan and Jewish rites and customs of which the symbolic meaning was Christianized. Light is everywhere the symbol of joy and of life-giving power, as darkness is of death and destruction. Fire, the most mysterious and impressive of the elements, the giver of light and of all the good things of life, is a thing sacred and adorable in primitive religions, and fire-worship still has its place in two at least of the great religions of the world. The Parsee adore fire as the visible expression of Ahura-Mazda, the eternal principle of light and righteousness; the Brahmans worship it as divine and omniscient.\(^{1}\) The Hindu festival of Diwali (Diyavali, from diy- light), when temples and houses are illuminated with countless lamps, is held every November to celebrate Lakshmi, the goddess of prosperity. In the ritual of the Jewish temple fire and light played a conspicuous part. In the Holy of Holies was a "cloud of light" (shekinah), symbolic of the presence of Yahweh, and while it stood the candlestick with six branches, on each of which and on the central one, the lamp normally burning, while in the forecourt was an altar on which the sacred fire was never allowed to go out. Similarly the Jewish synagogues have each their eternal lamp; while in the religion of Islam lighted lamps mark places and things specially holy; thus the Ka’ba at Mecca is illuminated by thousands of lamps hanging from the gold and silver rods that connect the columns of the surrounding colonnade.

The Greeks and Romans, too, had their sacred fire and their ceremonial lights. In Greece the Lampedromia or Lampadephoria (torch-race) had its origin in ceremonies connected with the lighting of the sacred fire. Pausanias (i. 26, § 6) mentions the golden lamp made by Callimachus which burned night and day in the sanctuary of Athena Polias on the Acropolis, and (vii. 22, §§ 2 and 3) tells of a statue of Helius Agora, in the market-place of Pharsae in Achaia, before which lamps were lighted. Among the Romans lighted candles and lamps formed part of the cult of the domestic tutelary deities; on all festivals doors were garnished and lamps lighted (Juvenal, Sat. xii. 92; Tertullian, Apol. xxxv.). In the cult of Isis lamps were lighted by day. In the ordinary temples were candelabra, e.g. that in the temple of Apollo Palatinus at Rome, originally taken by Alexander from Thebes, which was in the form of a tree from the branches of which lights hung like fruit. In comparing pagan with Christian usage it is important to remember that the lamps in the pagan temples were not symbolical, but votive offerings to the gods. Torches and lamps were also carried in religious processions.

The pagan custom of burying lamps with the dead conveyed no such symbolical meaning as was implied in the late Christian custom of placing lights on and about the tombs of martyrs and saints. Its object was to provide the dead with the means of obtaining light in the next world, a wholly material conception; and the lamps were for the most part unlighted. It was of Asiatic origin, traces of it having been observed in Phoenicia and in the Punic colonies, but not in Egypt or Greece. In Europe it was confined to the countries under the domination of Rome.\(^{2}\)

In Christianity, from the very first, fire and light are conceived as symbols, if not as visible manifestations, of the divine nature and the divine presence. Christ is the "true Light" (John i. 9), and at his transfiguration "the fashion of his countenance was altered, and his raiment was white and glistening" (Luke ix. 29); when the Holy Ghost descended upon the apostles, "there appeared unto them cloven tongues of fire, and it sat upon each of them" (Acts ii. 3); at the conversion of St Paul "there shined round him a great light from heaven" (Acts ix. 3); while the glorified Christ is represented as standing in the midst of seven candlesticks . . . his head and hairs white like wool, as white as snow; and his eyes as a flame of fire" (Rev. i. 14, 15). Christians are "children of Light" at perpetual war with "the powers of darkness."

All this might very early, without the incentive of Jewish and pagan example, have affected the symbolic ritual of the primitive Church. There is, however, no evidence of any ceremonial use of lights in Christian worship during the first two centuries. It is recorded, indeed (Acts xx. 8) that on the occasion of Paul's preaching at Alexandria in Troas, "there were many lights in the upper chamber"; but this was at night, and the most that can be hazarded is that a specially large number were lighted as a festive illumination, as in modern Church festivals (Martigny, Dict. des anciens chrêts). As to a purely ceremonial use, such early evidence as exists is all the other way. A single sentence of Tertullian (Apol.xxxv.) sufficiently illuminates Christian practice during the 2nd century. "On days of rejoicing," he says, "we do not shake our door-posts with laurels nor encroach upon the day-light with lamps" (die laeto non laures postes obumbramus nec lucernis diem infringimus). Lactantius, writing early in the 4th century, is more sarcastic in his references to the heathen practice. "The lifeless lights," he says, "as though to one who is in darkness. Can he be thought sane who offers the light of lamps and candles to the Author and Giver of all light?" (Dis. Inst. vi. de vero cultu, cap. 2, in Migne, Patr. lat. vi. 639).\(^{3}\) This is primarily an attack on votive lights, and does not necessarily exclude their ceremonial use in other ways. There is, indeed, evidence that they were so used before Lactantius wrote. The 34th canon of the synod of Elvira (305), which was contemporary with him, forbade candles to be lighted in cemeteries during the daytime, which points to an established custom as well as to an objection to it; and in the Roman catacombs lamps have been found of the 2nd and 3rd centuries which seem to have

\(^{1}\) O 'Fire, thou knowest all things!' See A. Bourquin, "Brahma-\(\text{n}\)a, ou rites sacrés des Brahmanes," in the Annales du Musee Guimet (Paris, 1884, t. vii.).

\(^{2}\) J. Toutain, in Darmenay and Saglio, Dictionnaire, t. vi. "Lucerna."

\(^{3}\) This is quoted with approval by Bishop Jewel in the homily Against Peri of Idolatry (see below).
been ceremonial or symbolic. Again, according to the Acta of St Cyprian (d. 258), his body was borne to the grave prae-
ceptuositus cerevis, and Prudentius, in his hymn on the martyrdom of St Lawrence (Peristeph. ii. 71, in Migne, Pat. lat. l. 300), says that in the time of St Laurentius, i.e. the middle of the 3rd century, candles stood in the churches of Rome on golden candelabra. The gift, mentioned by Anastasius (in Sylg.), made by Constantine to the Vatican basilica, of a pharum of gold, garnished with 300 dolphins each holding a lamp, to be placed before St Peter's tomb, points also to a custom well established before Christianity became the state religion.

Whatever previous custom may have been—and for the earliest ages it is difficult to determine absolutely owing to the fact that the Christians held their services at night—by the close of the 4th century the ceremonial use of lights had become firmly established in the Church. This is clearly to pass by much other evidence, from the controversy of St Jerome with Vigilantius.

Vigilantius, a presbyter of Barcelona, still occupied the position of Tertullian and Lactantius in this matter. "We see," he wrote, "a rite peculiar to the pagans introduced into the churches on pretext of religion, and, while the sun is still shining, a mass of wax tapers lighted." A great number of the bishops of the 8th century wrote against the use of candelabra, either with contemptible little candles (de vitiisimis cereolis) "Jerome, the most influential theologian of the day, took up the cudgels against Vigilantius (he ought to be called Dornmctus?), who, in his letter to his fatherly friend, had directed him ("to open his foul mouth and send forth a filthy stink against the relics of the holy martyrs") (Hier. Ep. cix. al. 53—ad Riparium Presbyt., in Migne, Pat. lat. p. 906). If candles are lit before their tombs, are they not the lights of idols of false gods? "In his treatise contra Vigilantium (Pat. lat. t. xxiii.)," he answers the question with much common sense. There can be no harm if ignorant and simple people, or religious women, light candles in honour of the blessed martyrs. "As for the idea of Valetudo, the practice which when done for idols was detestable is acceptable when done for the martyrs. As in the case of the woman with the precious box of ointment, it is not the gift that merits reward, but the faith that inspires it. As for lights in the churches, he adds, "the Pope of Rome and the rest of the faithful are the lamps of the faithful, the size of the flame, the light of the sun, these are the light of the whole Church, the Church is the light of the world," (§ 7)—this seems to point to the fact that the ritual use of lights in the church services, so far as already established, arose from the conservative habit as determined by the development of liturgical vestments, i.e. the lights which had been necessary at the nocturnal meetings were retained, after the hours of service had been altered, and invested with a symbolical meaning.

Already they were used at most of the conspicuous functions of the Church. Paulinus, bishop of Nola (d. 437), describes the altar at the eucharist as "a small altar with two lights," and even mentions the "eternal lamp," (§ 3) For their use at baptisms we have, among much other evidence, that of Zeno of Verona for the West, and that of Gregory of Nazianzus for the East. Their use at funerals is illustrated by Eusebius's description of the burial of Constantine, and Jerome's account of that of St Paula. At ordinations they were used, as is shown by the 6th canon of the council of Carthage (398), which decrees that the acolyte is to hand to the newly ordained deacon ceroferator cum ceroe.

This symbol—what it was—was not pagan, i.e. the lamps were not placed in the graves as part of the furniture of the dead—in the Catacombs they are found only in the niches of the galleys of the Sepulchralia—nor can they have been votive in the sense popularized later.

1 "Clara coronandur densis alitaria lychnis" (Poem. De S. Felicitate natulatium, xiv. 99, in Migne, Pat. lat. l. 467).
2 "Cl. in actuاسي кварум scoptis tum apriciorum usum."
3 Sal, ignis et oleum" (Lib. 1. Tract. xiv. 4, in Migne, x. 358).
4 "Sanct. Pasch. c. 2; Migne, Pat. graec., xxxvi. 62a."
5 "Quae quibusdam idem ut in sacris chrerum, thymacum thine tibi oporteat." (El. Constitution, iv. 1.)
6 Cun alli Nichelles lampadas cerevis proferent, ali choras pallantium ducentur" (Ep. civili. ad Eustochium virginiem, in Migne).

As to the blessing of candles, according to the Liber pontificialis Pope Zosimus in 417 ordered these to be blessed, and the Gallican and Mozarabic rituals also provided for this ceremony. The Feast of the Purification of the Virgin, known as Candlemas (q.v.), because on this day the candles for the whole year are blessed, was established—according to some authorities—by Pope Gelasius I. about 492. As to the question of "altar lights," however, it must be borne in mind that these were not placed upon the altar, or on a table behind it, until the 12th century. These were originally the candles carried by the deacons, according to the Ordo Romanus (i. 8; ii. 5; iii. 7) seven in number, which were set down either on the steps of the altar, or, later, behind it. In the Eastern Church, to this day, there are no lights on the high altar; the lighted candles stand on a small altar beside it, and at various parts of the service are carried by the lectors or acolytes before the chanting of prayers, and consecrated by the priest as the lights used by Paulinus as crowning the altar were either grouped round it or suspended in front of it; they are represented by the sanctuary lamps of the Latin Church and by the crown of lights suspended in front of the altar in the Greek.

To trace the gradual elaboration of the symbolism and use of ceremonial lights in the Church, until its full development and systematization in the middle ages, would be impossible here. It must suffice to note a few stages in the process. The burning of lights before the tombs of martyrs led naturally to their being burned also before relics and lastly before images and pictures. This latter practice, hotly denounced as idolatry during the iconoclastic controversy (see Iconoclasm), was finally established as orthodox by the second general council of Nicaea (787), which restored the worship of images. A later development, however, by which the lights were kept for the first time has been regarded as objects of worship; they came to have other lights burned before them, was condemned as idolatrous by the synod of Noyon in 1344. The passion for symbolism extracted ever new meanings out of the candles and their use. Early in the 6th century Emundus, bishop of Pavia, pointed out the three-fold elements of a wax-candle (Opusc. i. x. and x.), each of which would make it an offering acceptable to God; the rush-wick is the product of pure water, the wax is the offspring of virgin bees, the flame is sent from heaven. Clearly, wax was a symbol of the Blessed Virgin and the holy humanity of Christ. The later middle ages developed the idea. Durandus, in his Rationale, interprets the wax as the body of Christ, the wick as his soul, the flame as his divine nature; and the consuming candle as symbolizing his passion and death.

This may be the paschal candle only. In some codices the text runs: "Per parochias consecrat licentiam benedicendi Cereum Paschale" (Du Cange, Glossarium, s.v. "Cereum Paschale"). In the Liber pontificalis, the consecration of wax in the church of Rubinius, the word cerus is in the text and "cera benedicenda cerae et laminae in privilegii Paschae." This canon states that candles and lamps are not blessed in some churches, and that inquiries have been made why we do it. In reply, the council decides that it should be done to celebrate the memory of the virgin: See Isidore of Seville, Conc., in Migne, Pat. lat. lxxiii. 356.

Du Cange, Glossarium, s.v. "Candela,"
Bees were believed, like fish, to be sexless.

20. Venerandis compactam elementis facem tibi, Domine, mancipa: in qua tria cupola munerum primum de impari numero complaciefit: quae quod gratia Deus veniet auctoriibus, non habetur incertum: unum quod de fletibus fluminum accedunt nutrimenta: alium de propitio tribuere Domini: tertio, in quarto partibus nulla participari damna virginitas: ignis etiam coelo infusus adhibetur" (Opusc. in. Migne, Pat. lat. t. 183.)
LIGHTS, CEREMONIAL USE OF

In the completed ritual system of the medieval Church, as still preserved in the Roman Catholic communion, the use of ceremonial lights falls under three heads. (1) They may be symbolic of the light of God's presence, of Christ as "Light of Light," or of the "children of Light" in conflict with the powers of darkness and "their every eye," and than expressions of joy on the occasion of great festivals. (2) They may be votive, i.e. offered as an act of worship (latria) to God. (3) They are, in virtue of their benediction by the Church, sacrosanct, and so forbidden for shams and bosh, and for the confusion of the powers of darkness. With one or more of these implications, they are employed in all the public functions of the Church. At the consecration of a church twelve lighted candles are placed in a circular order at the place where these are anointed by the bishop with holy oil, and on every anniversary these are relighted; at the dedication of an altar tapers are lighted and censed at each place, each one an anathema against the Roman Rite, i.e. De eccl. dedicat, seu conscrat. At every liturgical service, and especially at Mass and at choir services, there must be at least two lighted tapers on the altar, as symbols of the presence of God and tributes of adoration. For the Mass the thirteenth candle is never lighted, but they may be lighted for the High Mass, four, five, and even more, but they must be used for the Mass, and then the thirteenth candle is lighted, and must be placed at the altar of the high altar, and five before the reserved Sacrament, as symbols of the eternal Presence. In practice, however, it is usual to have only one lamp lighted before the tabernacle in which the Host is reserved. The special symbol of the real Presence of Christ in the Host is the thirteenth candle, at the moment of consecration and kept burning until the communion. The same symbol is intended by the lighted tapers which must accompany the Host wherever it is carried in procession, or to the sick and dying. As symbols of light and joy a candle is held on each side of the deacon when reading the Gospel at Mass; and the same symbolism underlies the multiplication of lights on festivals, the number varying with the importance of the occasion. As to the number of these latter no rule is laid down. They differ in liturgical functions in that, whereas these must be tapers of pure beeswax or lamps (fed with pure wax) they may be candles by consent of the Bishop, and in certain circumstances, those used merely to add splendour to the celebration may be of any material; the only exception being, that in the decoration of the altar gas-lights are forbidden.

In general the ceremonial use of lights in the Roman Catholic Church is a dramatic representation in flux of the life of Tenebrae. of Christ and of the whole scheme of salvation. On Easter Eve the new fire, symbol of the light of the newly risen Christ, is produced, and from this are kindled all the lights used through the week by the clergy and other members of the clergy (De eccles. disciplina, i. 409). Twelve priests should stand about the bishop, holding in their hands lighted torches, which at the conclusion of the Service they should cast down and trample under foot. When the excommunication is removed, the symbol of reconciliation is the handing to the penitent of a burning taper.

As a result of the Reformation the use of ceremonial lights was greatly modified, or totally abolished in the Protestant Churches. In the Reformed and in the others, where the altar lights were, with the rest, done away with entirely as popish and superstitious. In the Lutheran Churches they were retained, and in Evangelical Germany they have even survived most of the other medieval rites and ceremonies (e.g. the use of vestments) which were not abolished at the Reformation itself.

In the Church of England the practice has been less consistent. The first Prayer-book of Edward VI. directed two lights to be placed on the altar. This direction was omitted in the second Prayer-book; but the "Ornaments Rubric" of Queen Elizabeth's Prayer-book seemed again to make them obligatory. The question of how far this did so is a much-disputed one and is connected with the whole problem of the meaning and scope of the rubric (see Vestments). An equal uncertainty reigns with regard to the actual usage of the Church of England from the Reformation onwards. Lighted candles certainly continued to decorate the holy table in Queen Elizabeth's chapel, to the scandal of Protestant zealots. They also seem to have been retained, at least for a while, in certain chapels of the college. Here, however, no mention of ceremonial candles in the details of the Order of the Church of England given by William Harrison (Description of England, 1570); and the attitude of the Church towards their use, until the ritualistic movement of the 17th century, would seem to be authoritatively expressed in the Third Part of the Sermon against Perill of Idolatry, which quotes with approval the views of Lactantius and compares "our Candle Religion" to that of the Eastern Churches.

1 All three conceptions are brought out in the prayers for the blessing of candles on the Feast of the Purification of the B.V.M. (Candlemas) a. d. 1316, and later, by the command of H. H. imperially to increase this liqward by the labour of all the workers in the perfection of wax . . . we beseech thee . . . to bless and sanctify these candles for the use of men, and the health of bodies and souls . . . (2) . . . these candles, which we thy servants desire to carry evermore may consummately shine offerings being worthily inflamed with the holy fire of thy most sweet charity, we may deserve . . . &c. (3) "O Lord Jesus Christ, the true light . . . mercifully grant, that as these lights enkindled with visible fire dispelling darkness and moving us from evil, so our souls may be enkindled and moved from evil by thy most holy and ineffable light . . . &c. (Missale Rom.) In the form for the blessing of candles extra diem Purificationis B. Mariae Virg. the virtue of the consecrated candles in dispelling demons is specially brought out: "that in whatever places they shall be lighted or placed, the princes of darkness may depart, and tremble, and their ministering spirits be troubled and disquieted. . . . all those who serve thee, Almighty God" (Rituale Rom.)

2 Altar candlesticks consist of five parts: the foot, stem, knob in the centre, bowl to catch the drippings, and pricket (a sharp point on which the candle is fixed). It is permissible to use a long tube, pointed to imitate a candle, in which is a smaller taper forced to the top by a spring (Cong. Rit., 11th May 1878).

3 This is common to the Eastern Churches also. Pilgrims from all parts of the East flock to Jerusalem to obtain the "new fire" on Easter Eve at the Church of the Holy Sepulchre. Here the fire is supposed to be miraculously sent from heaven. The rush of the people to obtain the "blessed fire" is so great, that order is maintained with difficulty by Mahomedan soldiers.

4 The origin of the Paschal Candle is lost in the mists of antiquity. According to the abbé Châtelan (quoted in Diderot's Encyclopédie, s. v. "Cierge") the Paschal Candle was not originally singing candles, but the wax column on which the dates of the movable feasts were inscribed. These were later written on paper and fixed to the Paschal Candle, a custom which in his day survived in the Cenacle churches.

5 These are found in the following rubrics: De eccles. disciplina, i. 409; Missale Rom., Rituale Rom.; Congregatio Regni Anglicani, November 1843; and the Rubricæ Eboracenses of the Percy MS. (Rolls Series, i. 67.)
with the “Gentiles Idolaters.” This pronunciation, indeed, though it certainly condemns the use of ceremonial lights in most of its late descendants, and particularly the conception of the most active offerings whether to God or to the saints, does not necessarily exclude, though it undoubtedly discourages, their purely symbolic use.1 In this connexion it is worth pointing out that the homily against idolatry was reprinted, without alteration and by the king’s authority, long after altar lights had been restored under the influence of the high church party supreme at court. Illegal under the Act of Uniformity they seem never to have been. The use of “wax lights and tapers” formed one of the indictments brought by P. Smart, a Puritan prebendary of Durham, against Dr Burgoyne, Cosin and others for setting up “superstitious ceremonies” in the cathedral “contrary to the Act of Uniformity.” The indictments were dismissed in 1628 by Sir James Whitekocke, chief justice of Chester and a judge of the King’s Bench, and in 1629 by Sir Henry Yelverton, a judge of Common Pleas and himself a strong Puritan (see Hierurgia Anglicana, ii. pp. 230 seq.). The use of ceremonial lights was among the indictments in the impeachment of Laud and other bishops by the House of Commons, but these were not based on the Act of Uniformity. From the Restoration onwards the use of ceremonial lights, though far from universal, was not unusual in cathedrals and collegiate churches.2 It was not, however, till the ritual revival of the 19th century that their use was at all widely extended in parish churches. The growing custom met with fierce opposition; the law was appealed to, and in 1872 the Privy Council declared altar lights to be illegal (Martin v. Mackonachie). This judgment, founded as was afterwards admitted on insufficient knowledge, produced no effect; and, in the absence of any authoritative pronouncement, advantage was taken of the ambiguous language of the Ornaments Rubric to introduce into many churches practically the whole ceremonial use of lights as practised in the pre-Reformation Church. The matter was again raised in the case of Read and others v. the Bishop of Lincoln (see Lincoln Judgement), one of the counts of the indictment being that the bishop had, during the celebration of Holy Communion, allowed two candles to be alight on a shelf or retable behind the communion table when they were not necessary for giving light. The archbishop of Canterbury, in whose court the case was heard (1850), decided that the mere presence of two candles on the table, burning during the service but lit before it began, was lawful under the first Prayer-Book of Edward VI. and had never been made unlawful. On the case being appealed to the Privy Council, this particular indictment was dismissed on the ground that the vicar, not the bishop, was responsible for the presence of the lights, the general question of the legality of altar lights being discreetly left open.

The “Lincoln Judgment.”

The custom of placing lighted candles round the bodies of the dead, especially when “lying in state,” has never wholly died out in Protestant countries, though their significance has long been lost sight of.3 In the 18th century, moreover, it was still customary in England to accompany a funeral with lighted candles.4 A paper plate representing a funeral cortège preceded and accompanied by boys, each carrying four lighted candles in a branched candlestick, there seems to be no record of candles having been carried in other processions in England since the Reformation. The usage in this respect in some “ritualistic” churches is a revival of pre-Reformation ceremonial.

Alterthümer), ii. 238-301; article “Claires et lampes,” in the Abbé J. A. Martigny’s Dict. des antiquités chrétiennes (Paris, 1865); the articles “Lichter” and “Kolometrien” (pp. 834 seq.) in Herzog-Hauck’s Realencyklopadie (3rd ed., Leipzig, 1901); the article “Lichter” in Diet., vol. xiv., 1882-1901), an excellent exposition of the symbolism from the Catholic point of view, also “Kerze” and “Lichter”: W. Smith and S. Cheetham, Dict. of chr. Antiquities (London, 1875-1880), i. 566 seq.; and Dr Welte’s Geschichte der lutherischen Kirche (Augsburg, 1879-1880), one of whose authorities is still this very volume.

LIGNE, CHARLES JOSEPH, PRINCE DE (1735-1814), soldier and writer, came of a princely family of Hainaut, and was born at Brussels in 1735. As an Austrian subject he entered the imperial army at an early age. He distinguished himself by his valour in the Seven Years’ War, notably at Breslau, Leuthen, Hochkirch and Maxen, and after the war rose rapidly to the rank of lieutenant field marshal. He became the intimate friend and counsellor of the emperor Joseph II., and, inheriting his father’s vast estates, lived in the greatest splendour and luxury till the War of the Bavarian Succession brought him again into active service. This war was short and eventful, and the prince then travelled in England, Germany, Italy, Switzerland and France, devoting himself impartially to the courts, the camps, the salons and the learned assemblies of philosophers and scientists in each country. In 1784 he was again employed in military work, and was promoted to Feldzeugmeister. In 1787 he was with Catherine II. in Russia, accompanied her in her campaign to the Crimea, and was made a field marshal by the empress. In 1788 he was present at the siege of Belgrade. Shortly after this he was invited to place himself at the head of the Belgian revolutionary movement, in which one of his sons and many of his relatives were prominent, but declined with great courtesy, saying that “he never revolted in the winter.” Though suspected by Joseph of collusion with the rebels, the two friends were not long estranged, and after the death of the emperor the prince remained in Vienna. His Brabant estates were overrun by the French in 1792-1793, and his eldest son killed in action at La Croix-du-Bois in the Argonne (September 14, 1792). He was given the rank of field marshal (1800) and an honorary command at court, living in spite of the loss of his estates in comparative luxury and devoting himself to literary work. He lived long enough to characterize the proceedings of the congress of Vienna with the famous mot: “Le Congrès danse mais ne marche pas.” He died at Vienna on the 13th of December 1814. His grandson, Eugene Lamoral de Ligne (1804-1890), was a distinguished Belgian statesman.

His collected works appeared in thirty-four volumes at Vienna during the last years of his life (Milanges militaires, litteraires, sentimentaires), and he bequeathed his manuscripts to the emperor’s Trabant Guard, of which he was captain (Œuvres posthumes, Dresden and Vienna, 1817). Selections were published in French and German (Œuvres choisies de M. le prince de Ligne (Paris, 1809); Lettres et pensées du Maréchal Prince de Ligne, ed. by Madame de Staël (1809); Œuvres historiques, litteraires … correspondance et lettres du Prince de Ligne militaires, écrasantes, et militaires, écrasantes, mérites de la terre, des armes; condemned, but not illicit, was abolished. The custom of placing lighted candles round the bodies of the dead, especially when “lying in state,” has never wholly died out in Protestant countries, though their significance has long been lost sight of. In the 18th century, moreover, it was still customary in England to accompany a funeral with lighted candles. A paper plate representing a funeral cortège preceded and accompanied by boys, each carrying four lighted candles in a branched candlestick, there seems to be no record of candles having been carried in other processions in England since the Reformation. The usage in this respect in some “ritualistic” churches is a revival of pre-Reformation ceremonial.

See the article “Lucerna,” by J. Toutain in Daremberg and Saglio’s Dict. des antiquités grecques et romaines (Paris, 1904); J. Marquet, “Römische Privatalterthümer” (vol. v. of Becker’s Rom. Alterthümer), ii. 238-301; article “Claires et lampes,” in the Abbé J. A. Martigny’s Dict. des antiquités chrétiennes (Paris, 1865); the articles “Lichter” and “Kolometrien” (pp. 834 seq.) in Herzog-Hauck’s Realencyklopadie (3rd ed., Leipzig, 1901); the article “Lichter” in Diet., vol. xiv., 1882-1901), an excellent exposition of the symbolism from the Catholic point of view, also “Kerze” and “Lichter”: W. Smith and S. Cheetham, Dict. of chr. Antiquities (London, 1875-1880), i. 566 seq.; and Dr Welte’s Geschichte der lutherischen Kirche (Augsburg, 1879-1880), one of whose authorities is still this very volume. A German version (Militärische Vorurteile und Phantasien, &c.) appeared as early as 1783. This work, though it deals lightly and cavalierly with the most important subjects (the prince even proposes to found an international society of the history of war), the reputation of generals being impartially weighed), is a military classic, and indispensable to the students of the post-Frederician period. On the whole, it may be said that the prince adhered to the school of St. Petersburg, the future of which will be found in Max Jähn’s Gesch. d. Kriegswoissenschaften, iii. 2901 et seq. Another very celebrated work by the prince is the mock autobiography of Prince Eugene (1809).

LIGNITE (Lat. lignum, wood), an imperfectly formed coal, usually brownish in colour, and always showing the structure of the wood from which it was derived (see Coal).

LIGNONIER, JOHN (Jean Louis) LIGNONIER, EARL (1680–1770), British Field Marshal, came of a Hugenot family of Castres in the south of France, members of which emigrated to England at the close of the 17th century. He entered the army as a volunteer under Marlborough. From 1702 to 1710 he was engaged, with distinction, in nearly every important battle and siege of the war. He was one of the first to mount the breach at the siege of Liége, commanded a company at the Schellenberg and at Blenheim, and was present at Menin (where he led the storming of the covered way), Ramillies, Oudenarde and Malplaquet (where he received twenty-three bullets through his clothing and remained unhurt). In 1712 he became governor of Fort St Philip, Minorca, and in 1718 was adjutant-general of the troops employed in the Vigo expedition, where he led the stormers of Fort Marin. Two years later he became colonel of the “Black Horse” (now 7th Dragoon Guards), a command which he retained for 29 years. His regiment soon attained an extraordinary degree of efficiency. He was made brigadier-general in 1735, major-general in 1739, and accompanied Stair in the Rhine Campaign of 1742–1743. George II. made him a Knight of the Bath on the field of Dettingen. At Fontenoy Ligonier commanded the British foot, and acted throughout the battle as adviser to the duke of Cumberland. During the "Fifty-Five" he was called home to command the British army in the Midlands, but in January 1746 was placed at the head of the British and British-paid contingents of the Allied army in the Low Countries. He was present at Rocoux (11th Oct. 1746), and, as general of horse, at Val (1st July 1747), where he led the last charge of the British cavalry. In this encounter his horse was killed, and he was taken prisoner, but was exchanged in a few days. With the close of the campaign ended Ligonier’s active career, but (with a brief interval in 1756–1757) he remained a military expert of the highest order until the close of his life. In 1757 he was made, in rapid succession, commander-in-chief of the 1st Foot Guards (now Grenadier Guards), and a peer of Ireland under the title of Viscount Ligonier of Enniskillen, a title changed in 1762 for that of Clonmel. From 1759 to 1762 he was master-general of the Ordnance, and in 1763 he became Baron, and in 1766 Earl, in the English peerage. In the latter year he became field marshal. He died in 1770. His younger brother, Francis, was also a distinguished soldier; and his son succeeded to the Irish peerage of Lord Ligonier.

See COMBS, J. L. Ligonier, une étude (Castres, 1866), and the histories of the 7th Dragoon Guards and Grenadier Guards.

LIGUORI, ALFONSO MARIA DEI (1696–1787), saint and archbishop of the Church of Rome, was born at Marianella, near Naples, on the 27th of September 1696, being the son of Giuseppe dei Liguori, a Neapolitan noble. He began life at the bar, where he obtained considerable practice; but the loss of an important suit, in which he was counsel for a Neapolitan noble against the grand duke of Tuscany, and in which he had entirely mistaken the force of a leading document, so mortified him that he withdrew from the legal world. In 1726 he entered the Congregation of Missions as a novice, and became a priest in 1726. In 1732 he founded the “Congregazione of the Most Holy Redeemer” at Scala, near Salerno; the headquarters of the Order were afterwards transferred to Nocera dei Pagani. His members, popularly called Liguiorians or Redemptorists, devote themselves to the religious instruction of the poor, more especially in country districts; Liguori specially forbade them to undertake secular educational work. In 1750 appeared his celebrated devotional book on the Glories of Mary; three years later came his still more celebrated treatise on moral theology. In 1755 this was much enlarged and translated into Latin under the title of Homo Apostolicus. In 1762, at the express desire of the pope, he accepted the bishopric of Sant'Agata dei Goti, a small town in the province of Benevent; though he had previously refused the archbishopric of Palermo. Here he worked diligently at practical reforms, being specially anxious to raise the standard of clerical life and work. In 1775 he resigned his bishopric on the plea of enfeebled health; he retired to his Redemptorists at Nocera, and died there in 1787. In 1796 Pius VII. declared him “venerable”; he was beatified by Pius VII. in 1816, canonized by Gregory XVI. in 1839, and finally declared one of the nineteen “Doctors of the Church” by Leo XIII. in 1879.

Liguori is the chief representative of a school of casuistry and devotional theology still abundantly represented within the Roman Church. Not that he was in any sense its founder. He was simply a fairly representative of the Italian piety of his day—amicable, ascetic in his personal habits, indefatigable in many forms of activity, and of more than respectable abilities; though the emotional side of his character had the predominance over his intellect. He was learned, as learning was understood among the Italian clergy of the 18th century; but he was a great man of critical faculty, and the inaccuracy of his quotations is proverbial. In his casuistical works he was a diligent compiler, whose avowed design was to take a middle course between the two current extremes of severity and laxity. In practice, he leaned constantly towards laxity. Eighteenth-century Italy looked on Liguori as a true son of Aquinas, and his doctrine of practical morality. But on certain points, Liguori's ideas and the views of his day were often so widely divergent that it is far from clear that Liguori's teaching was in any respect inferior to that of his contemporaries. But on certain points, Liguori's ideas and the views of his day were often so widely divergent that it is far from clear that Liguori's teaching was in any respect inferior to that of his contemporaries. But on certain questions, Liguori's ideas and the views of his day were often so widely divergent that it is far from clear that Liguori's teaching was in any respect inferior to that of his contemporaries. But on certain questions, Liguori's ideas and the views of his day were often so widely divergent that it is far from clear that Liguori's teaching was in any respect inferior to that of his contemporaries.

Liguori's time there were four ways of answering the question. Strict moralists—called rigorists, or "tutorists"—maintained that the austerer opinion ought always to be followed; dancing on Sundays was certainly wrong, if any good authorities had declared it to be so. Probabilists maintained that the more general opinion ought to prevail, irrespectively of whether it was the stricter or the laxer; dancing on Sunday was perfectly lawful, if the majority of casuists approved it. Probabilists argued that any opinion might be held, if it could show good authority on its side, even if there were as little better argument in support of the other. Liguori's teaching was in any respect inferior to that of his contemporaries. But on certain questions, Liguori's ideas and the views of his day were often so widely divergent that it is far from clear that Liguori's teaching was in any respect inferior to that of his contemporaries. But on certain questions, Liguori's ideas and the views of his day were often so widely divergent that it is far from clear that Liguori's teaching was in any respect inferior to that of his contemporaries. But on certain questions, Liguori's ideas and the views of his day were often so widely divergent that it is far from clear that Liguori's teaching was in any respect inferior to that of his contemporaries. But on certain questions, Liguori's ideas and the views of his day were often so widely divergent that it is far from clear that Liguori's teaching was in any respect inferior to that of his contemporaries.
parishioners to dance on Sunday, if the practice had won widespread toleration; on the other hand, they could not relax the usual discipline of the church on the strength of a few unguarded opinions of too indulgent casuists. Thus the Ligurian system surpassed all its predecessors in securing uniformity in the confessional on a basis of established usage, two advantages amply sufficient to ensure its speedy general adoption within the Church of Rome.

LIGURES BAEBIANI—LIGURIA

LIGURES BAEBIANI, in ancient geography, a settlement of Ligurians in Samnium, Italy. The towns of Taurasia and Cisana in Samnium had been captured in 208 B.C. by the consul L. Cornelius Scipio Barbatus, and the territory of the former remained Roman state domain. In 180 B.C. 47,000 Ligurians from the neighbourhood of Luna (Ligures Apuani), with women and children, were transferred to this district, and two settlements were formed taking their names from the consuls of 181 B.C., the Ligures Baebiani and the Ligures Corneliani. The site of the first town lies 15 m. N of Beneventum, on the road to Saequinum and Asellonia. In its ruins several inscriptions have been found, notably a large bronze tablet discovered in a public building in the town of the date 172 B.C. and an altar of the alimentary institution founded by Trajan here (see Veleia). A sum of money was lent to landed proprietors of the district (whose names and estates are specified in the inscription), and the interest which it produced formed the income of the institution, which, on the model of that of Veieia, would have served to support a little over one hundred children. The capital was 41,000 sesterces, and the annual interest probably at 5% i.e. 2,000 sesterces (4,018 and £201 respectively). The site of the other settlement—that of the Ligures Corneliani—is unknown.

See T. Mommesen in Corp. Inscr. Lat. ix. (Berlin, 1883), 125 sqq. (T. As.)

LIGURIA, a modern territorial division of Italy, lying between the Ligurian Alps and the Apennines on the N., and the Mediterranean on the S. and extending from the frontier of France on the W. to the Gulf of Spezia on the E. Its northern limits touch Piedmont and Lombardy, while Emilia and Tuscany fringe its eastern borders, the dividing line following as a rule the summits of the mountains. Its area is 2,037 sq. m. The railway from Pisa skirts the entire coast of the territory, throwing off lines to Parma from Sarzana and Spezia, to Milan and Turin from Genoa, and to Turin from Savona, and there is a line from Ventimiglia to Cuneo and Turin by the Col di Tenda. Liguria embraces the two provinces of Genoa and Porto Mauriello (Imperia), which once formed the republic of Genoa. Its mountainous masses slope gently northward toward the Po, descending, however, abruptly into the sea at several points; the narrow coastal district, famous under the name of the Riviera (q.v.), is divided at Genoa into the Riviera di Ponente towards France, and the Riviera di Levante towards the east. Its principal products are wheat, maize, wine, oranges, lemons, fruits, olives and potatoes, though the olive groves are being rapidly supplanted by flower-gardens, which grow flowers for export. Copper and iron pyrites are mined. The principal industries are iron-works, foundries, iron shipbuilding, engineering, and boiler works (Genoa, Spezia, Sampierdarena, Sestri Ponente, &c.), the production of coconuts, and the manufacture of cottons and woolens. Owing to the sheltered situation and the mildness of their climate, many of the coast towns are chosen by thousands of foreigners for winter residence, while the Italians frequent them in summer for sea-bathing. The inhabitants have always been adventurous seamen—Columbus and Amerigo Vespucci were Genoese,—and the coast has several good harbours, Genoa, Spezia and Savona being the best. In educational and general development, Liguria stands high among the regions of Italy. The populations of the respective provinces and their chief towns are, according to the census of 1901 (popolazione residente o legale)—province of Genoa, pop. 931,156; number of communes 197; chief towns—Genoa (219,597), Spezia (66,265), Savona (38,648), Sampierdarena (34,084), Sestri Ponente (17,225). Province of Porto Maurizio, pop. 144,604, number of communes 106; chief towns—Porto Maurizio (7207), S. Remo (20,027), Ventimiglia (11,468), Oneglia (822). Total for Liguria, 1,075,760.

The Ligurian coast became gradually subject to the Romans, and the road along it must have been correspondingly opened: up to the end of the Hannibalic war the regular starting-point for Spain by sea was Pisa, in 155 B.C. it was the harbour of Luna (Genoa of Spezia), though Genoa must have become Roman a little before this time. Liguria is also said to have been crossed by the Pyrenees. The towns of Liguria, forming the ninth region of Augustus, was thus far more extensive than the modern, including the country on the north slopes of the Apennines and Maritime Alps between the Tebra and the Po, and extending a little beyond Albintini. Of the western Augustus' line between the Alpes Maritimes and the Alpes Cottiae. Towns of importance were few, owing to the nature of the country. Dertona was the only colony, and Alba Pompeia, Augusta Baggiornorum, Pollentia, Hasta, Aquae Statiellae, and Genova may also be mentioned; but the Ligurians dwelt entirely in villages, and were organized as tribes. The mountainous character of Liguria made the spread of culture difficult; it remained a forest district, producing timber, cattle, ponies, mules, sheep, &c. Oil and wine had to be imported, and when the cultivation of the olive began is not known.

The arrangement made by Augustus lasted until the time of Diocletian, when the two Alpine provinces were abolished, and the watershed became the boundary between Italy and Gaul. At this time we find the name Liguria extended as far as Milan, while in the 6th century the old Liguria was separated from it, and under the Lombards formed the fifth Italian province under the name of Alpes Cottiae. In the middle ages the ancient Liguria north of the Apennines fell to Piedmont and Lombardy, while that to the south, with the coast strip, belonged to the republic of Genoa. (T. As.)

Archaeology and Philology.—It is clear that in earlier times the Ligurians occupied a much more extensive area than the Augustan region; for instance Strabo (i. 2, 92; iv. 1, 7) gives earlier authorities for their possession of the land on which the Greek colony of Massalia (Marseilles) was founded; and Thucydides (vi. 2) speaks of a settlement of Ligurians in Spain who expelled the Sicani thence. Southward their domain extended as far as Pisa on the coast of Etruria and Arretium inland in the

1 The dividing line between Liguria and Etruria was the lower course of the river Macra (Magra), so that, while the harbour of Luna was in the former, Luna itself was in the latter.
time of Polybius (ii. 6), and a somewhat vague reference in Lycophron (line 1351) to the Ligurians as enemies of the founders of Agylla (i.e. Caere) suggests that they once occupied even a larger tract to the south. Seneca (Cons ad Helv. vii. 9) states that the population of Corsica was partly Ligurian. By combining traditions recorded by Dionysius (i. 22; xiv. 37) and others (e.g. Serv. ad Aen. xi. 337) as having been held by Cato the Censor and by Philistus of Syracuse (383 B.C.) respectively, Professor Ridgeway (Who were the Romans? London, 1908, p. 3) decides in favour of identifying the Ligurians with a tribe called the Abrigines who occupy a large place in the early traditions of Italy (see Dionysius i. cc. 10 ff.); and who at all events be regarded with reasonable certainty as constituting an early Pre-Roman and pre-Tuscan stratum in the population of Central Italy (see LATIN). For a discussion of this question see VoLsCi. Ridgeway concludes that the language of the Ligurians, as well as their antiquities, was identical with that of the early Latins, and with that of the Plebeians of Rome (as contrasted with that of the Patrician or Sabine element), see ROMe: History (ad. init.). The archaeological side of this important question is difficult. Although great progress has been made with the study of the different strata of remains in prehistoric Italy and of those of Liguria itself (see for instance the excellent Introduction à l'histoire romaine by Basile Modestov (Paris, 1907, p. 122 ff.) and W. Ridgeway's Early Age of Greece, p. 240 ff.) no general agreement has been reached among archaeologists as to the particular races who are to be identified as the authors of the early strata, earlier, that is, than that stratum which represents the Etruscans.

On the linguistic side some fairly certain conclusions have been reached. Ardois de Jussabine (Les premiers habitants de l'Europe, ed. 2, Paris, 1889-1894) pointed out the great frequency of the suffix -asow (and -asow) both in ancient and in modern Ligurian districts, and as far north as Carnunus near Metz, and also in the eastern Alps and in Spain. He pointed out also, what can scarcely be doubted, that the great mass of the Ligurian proper names (e.g. the streams Vinelasca, Porcoroba, Comberana; mons Tuledo; Venascum), have a definite Indo-European character. Farther Karl Müllenhof in vol. iii. of his Deutsche Alterthumskunde (Berlin, 1898) made a careful collection of the proper names reserved in Latin inscriptions of the Ligurian districts, such as the Tabula Gennatium (C.I.L. i. 99) of 117 B.C. A complete collection of all Ligurian place and personal names known has been made by S. Elizabeth Jackson, B.A., and the collection is to be combined with the inscriptionsal remains of the district in The Pre-Latian Dialects, edited by R. S. Conway (see The Proceedings of the British Academy). Following Kretschmer Kuhn's Zeitschrift (xxviii. 97), who discussed several inscriptions found near Ornassoso (Lago Maggiore) and concluded that they showed an Indo-European language, Conway, though holding that the inscriptions are more Celtic than Ligurian, pointed out strong evidence in the ancient place names of Liguria that the language spoken there in the period which preceded the Roman conquest was Indo-European, and belonged to a definite group, namely, languages which preserved the original g as Latin did, and did not convert it into p as did the Umbro-Satine tribes. The same is probably true of Venetia (see Venetii), and of an Indo-European language preserved on inscriptions found at Coligny and commonly referred to the Sequani (see Comptes Rendus de l'Ac. d'Ins., Paris, 1897, 703; E. B. Nicholson, Sequinian, London, 1898; Thurneysen, Zeitschr. f. Kelt. Phil., 1899, 533). Typically Ligurian names consisted of the characteristic word molo—"stone" as in molis Bisiiemiuem (C.I.L. v. 7749), Intimelium and the modern Vintimiglia. The tribal names Solici, Stonici, clearly contain the same element as Lat. aquil- (dwellers on the plain), salti-cola, &c., namely quel, cf. Lat. in-quitinus, colo, Gr. polieus, talleas. And it should be added that the Ligurian ethnica show the prevailing use of the two suffixes -co and -ati, which there is reason to refer to the pre-Roman stratum of population in Italy (see VoLsCi).

Besides the authorities already cited the student may be referred to C. Pauli, Alterthumskunde, vol. i., especially for the alphabet of the insc.; W. Ridgeway, Who were the Romans? (followed by the abstract of a paper by the present writer) in The Proceedings of the Swedish Academy, vol. iii. p. 53; and to W. H. Hall, The Romans on the Riviera and the Rhone (London, 1898); Issel's Lo Liguria geologico e preistorica (Genoa, 1892). A further batch of Colto-Ligurian inscriptions from Giulianova near Bellizona (Canton Ticino) is published by G. H. Herbig, in the Anzeiger f. Schweizer Alterthumskunde, vii. (1905-1906), p. 187; and one of the same class by Elia Lattes, Di un' Iscr. anti-Romana trovata a Caregna sul Lago d'Oria (Alli d. r. Accad. d. Scienze di Torino, xxxix., Feb. 1904).

LI HUNG CHANG (1825-1901), Chinese statesman, was born on the 16th of February 1825 at Ho-fêi, in N'gan-hui. From his earliest youth he showed marked ability, and when quite young he took his bachelor degree. In 1847 he became a Ta-tch'i, or graduate of the highest order, and two years later was admitted into the imperial Hanlin college. Shortly after this the central provinces of the empire were invaded by the Taiping rebels, and in defence of his native district he raised a regiment of militia, with which he did such good service to the imperial cause that he attracted the attention of Tsêng Kuo-fan, the generalissimo in command. In 1850 he was transferred to the province of Fu-kien, where he was given the rank of taotai, or intendent of circuit. But Tsêng had not forgotten him, and at his request Li was recalled to take part against the rebels. He founded his cause supported by the "Ever Victorious Army," which, after having been raised by an American named Ward, was finally placed under the command of Charles George Gordon. With this support Li gained numerous victories leading to the surrender of Suchow and the capture of Nanking. For these exploits he was made governor of Kiangsu, was decorated with a yellow jacket, and was created an earl. An incident connected with the surrender of Suchow, however, left a lasting stain upon his character. By an arrangement with Gordon the rebel wangs, or princes, yielded Nanking on condition that their lives should be spared. In spite of the assurance given them by Gordon, Li ordered their instant execution. This breach of faith so aroused Gordon's indignation that he seized a rifle, intending to shoot the falsifier of his word, and would have done so had not Li saved himself by flight. On the suppression of the rebellion (1864) Li took up his duties as governor, but was not long allowed to remain in civil life. On the outbreak of the rebellion of the Nien-fel, a remnant of the Taipings, in Ho-nan and Shan-tung (1866) he was ordered again to take the field, and after some misadventures he succeeded in suppressing the movement. A year later he was appointed viceroy of Hukwang, where he remained until 1876, when the government of Shan-tung was decreed, and he transferred his transfer to the scene of the outrage. He was, as a natural consequence, appointed to the viceroyalty of the metropolitan province of Chihli, and justified his appointment by the energy with which he suppressed all attempts to keep alive the anti-foreign sentiment among the people. For his services he was made imperial tutor and member of the grand council of the empire, and was decorated with many-eyed peacocks' feathers.

To his duties as viceroy were added those of the superintendent of trade, and from that time until his death, with a few intervals of retirement, he practically conducted the foreign policy of China. He concluded the Chifu convention with Sir Thomas Wade (1876), and thus ended the difficulty caused by the murder of Mr Margery in Yunnan; he arranged treaties with Peru and Japan, and he actively directed the Chinese policy in Korea. On the death of the emperor T'ung-chi in 1875 he, by suddenly introducing a large body of troops, seized on and occupied his post, and when his protector was put on the throne under the tutelage of the two dowager empresses; and in 1886, on the conclusion of the Franco-Chinese war, he arranged a treaty with France. Li was always strongly impressed with the necessity of strengthening the empire, and when viceroy of Chihli he raised a large well-drilled and well-armed force, and spent vast sums both in fortifying Port Arthur and the Taku forts and in increasing the navy. For years he had watched the successful reforms effected in Japan and had a well-founded dread of coming into conflict with that empire. But
in 1864, events forced his hand and, in consequence of a dispute as to the relative influence of China and Japan in Korea, war broke out. The result proved the wisdom of Li's fears. Both on land and at sea the Chinese forces were ignominiously routed, and in 1865, on the fall of Wei-hai-wei, the emperor sued for peace. With characteristic subterfuge his advisers suggested as peace envoys persons whom the Mikado very properly and promptly refused to accept, and finally Li was sent to represent his imperial master at the council assembled at Shimonskii. With great diplomatic skill Li pleased the cause of his country, but finally had to agree to the cession of Formosa, the Pescadores, and the Liaotung peninsula to the conquerors, and to the payment of an indemnity of 200,000,000 taels. By a subsequent arrangement the Liaotung peninsula was restored to China, in exchange for an increased indemnity. During the peace discussions at Shimonskii, as Li was being borne through the narrow streets of the town, a would-be assassin fired a pistol point-blank in his face. The wound inflicted was not serious, and after a few days' rest Li was able to take up again the suspended negotiations.

In 1866 he represented the emperor at the coronation of the tsar, and visited Germany, Belgium, France, England, and the United States. In 1867 services were demanded at Peking, where he was virtually constituted minister for foreign affairs; but in 1900 he was transferred to Canton as viceroy of the two Kwangs. The Boxer movement, however, induced the emperor to recall him to the capital, and it was mainly owing to his exertions that, at the conclusion of the outbreak, a protocol of peace was signed in September 1901. For many months his health had been failing, and he died on the 7th of November 1901. He left three sons and one daughter.

LILAC, or Pipe Tree (Syringa vulgaris), a tree of the olive family, Oleaceae. The genus contains about ten species of ornamental hardy deciduous shrubs native in eastern Europe and temperate Asia. They have opposite, generally entire leaves and large panicled small regular flowers, with a bell-shaped calyx and a 4-lobed cylindrical corolla, with the two stamens characteristic of the order attached at the mouth of the tube. The common lilac is said to have come from Persia in the 16th century, but is doubtfully indigenous in Hungary, the borders of Moldavia, &c., and in parts of S. Europe; it is, however, a native of Persia and is described by Gerard (Harb., 1597), who calls it the white and the blue pipe privets. The former is the common privet, Ligustrum vulgare, which, and the ash tree, Fraxinus excelsior, are the only members of the family native in Great Britain. The latter is the lilac, as both figure and description agree accurately with it. It was carried by the European colonists to north-east America, and is still grown in gardens of the northern and middle states.

There are many fine varieties of lilac, both with single and double flowers; they are among the commonest and most beautiful of spring-flowering shrubs. The so-called Persian lilac of gardens (S. dubia, S. chinensis var. Rothomagensis), also known as the Chinese or Rouen lilac, a small shrub 4 to 6 ft. high with intense violet flowers appearing in May and June, is considered to be a hybrid beard in plant names. The Persian lilac, a native of Persia and Afghanistan, a shrub 4 to 7 ft. high with bluish-purple or white flowers. Of other species, S. josikaea, from Transylvania, has scentless bluish-purple flowers; S. Emodi, a native of the Himalayas, is a handsome shrub with large and dense panicles of purple or white strongly scented flowers. Lilacs grow freely and flower profusely in almost any soil and situation, but when neglected are apt to become choked with suckers which are readily propagated by means of these suckers.

Syringa is also a common name for the mock-orange Philadelphcus coronarius (nat. ord. Saxifragaceae), a handsome shrub 10 to 12 ft. high, with spiny leaves and clusters of white flowers which have a strong orange-like scent. It is a native of western Asia, and perhaps some parts of southern Europe.

LILBURNE, JOHN (c. 1614–1657), English political agitator, was the younger son of a gentleman of good family in the county of Durham. At the age of twelve he was apprenticed to a clothier in London, but he appears to have early addicted himself to the "contention, novelties, opposition of government, and violent and bitter expressions" for which he afterwards became so conspicuous as to provoke the saying of Harry Marten (the regicide) that, "if the world was emptied of all but John Lilburn, I would quarrel with John, and John with Lilburn." He appears at one time to have been law-clerk to William Prynne. In February 1638, for the part he had taken in importing and circulating The Litany and other publications of John Bastwick and Prynne, offensive to the bishops, he was sentenced by the Star Chamber to be publicly whipped from the Fleet prison to Palace Yard, Westminster, there to stand for two hours in the pillory, and afterwards to be kept in gaol until a fine of £500 had been paid. He devoted his enforced leisure to his favourite form of literary activity, and did not regain his liberty until November 1640, one of the earliest recorded speeches of Oliver Cromwell being made in support of his petition to the House of Commons (Nov. 5, 1640). In 1641 he received an indemnity of £5000. He now entered the army, and in 1642 was taken prisoner at Brentford and tried for his life; sentence would no doubt have been executed had not the parliament by threatening reprisals forced his exchange. He soon rose to the rank of lieutenant-colonel, but in April 1645, having become disenchanted with the conduct of Cromwell, he left the army and refusing to take the covenant, he resigned his commission, pretending the same time to the Commons a petition for considerable arrears of pay. His violent language in Westminster Hall about the speaker and other public men led in the following July to his arrest and committal to Newgate, whence he was discharged, however, without trial, by order of the House, in October. In January 1647 he was committed to the Tower for accusations against Cromwell, but was again set at liberty in time to become a disappointed spectator of the failure of the "Levellers" or ultrademocratic party in the army at the Ware rendezvous in the following November. The scene produced a deep impression on his mind, and in February 1649 he along with other petitioners presented to the House of Commons a paper entitled The Serious Apprehensions of a part of the People on behalf of the Commonwealth, which he followed up with a pamphlet, England's New Chains Discovered, criticizing Ireton, and another exposing the conduct of Cromwell, Ireton and other leaders of the army since June 1647 (The Hunting of the Foxes from Newmarket and Tripple Erection of the Tower). The "beagles" being Lilburne, Richard Overton, William Walwyn, Prince (and another). Finally, the Second Part of England's New Chains Discovered, a violent outburst against the "dominion of a council of state, and a constitution of a new and unexperienced nature," became the subject of discussion in the House, and led anew to the imprisonment of its author in the Tower on the 11th of April. His trial in the following October, on a charge of seditious and scandalous practices against the state, resulted in his unanimous acquittal, followed by his release in November. In 1650 he was advocating the release of trade from the restrictions of chartered companies and monopolists.

In January 1652, for printing and publishing a petition against Sir Arthur Hesilrige and the Haberdashers' Hall for what he conceived to have been an injury done to his uncle George Lilburne in 1649, he was sentenced to pay fines amounting to £2000, and to be banished the Commonwealth, with prohibition of return under the pain of death. In June 1653 he nevertheless came back from the Low Countries, where he had busied himself pamphleteering in favour of popular agitation as was possible, and was immediately arrested; the trial which followed from the 13th of July to the 20th of August, issued in his acquittal, to the great joy of London, but it was nevertheless thought proper to keep him in captivity for "the peace of the nation." He was detained successively in the Tower, in Jersey, in Guernsey and in Dover Castle. At Dover he came under Quaker influence, and signified his readiness at last to be done with "carnal sword fightings and fleshly bustings and contests"; and in 1655, on giving security for his good behaviour, he was set free. He now settled at Eltham in Kent, frequently preaching at Quaker meetings in the neighbourhood during the brief remainder of his troubled life. He died on the 29th of August 1657.
LILIACEAE

His brother, Colonel Robert Liburne, was among those who signed the death-warrant of Charles I. In 1656 he was M.P. for the East Riding of Yorkshire, and at the restoration was sentenced to life-long imprisonment. See D. Masson, Life of Milton (iv. 120); Clement Walker (History of Independency, ii. 247); W. Godwin (Commonwealth, iii. 163-177), and Robert Bisset (Omitted Chapters of the History of England, 191-251).

LILIACEAE, in botany, a natural order of Monocotyledons belonging to the series Liliflorae, and generally regarded as representing the typical order of Monocotyledons. The plants are generally perennial herbs growing from a bulb or rhizome, sometimes shrubby as in butcher's-broom (Ruscus) or tree-like as in species of Dracaena, Yucca or Aloe. The flowers are with few exceptions hermaphrodite, and regular with parts in threes (fig. 5), the perianth which is generally petaloid occupying the two outer whors, followed by two whors of stamens, with a superior ovary of three carpels in the centre of the flower; the ovary is generally three-chambered and contains an indefinite number of anatropous ovules on placenta (see fig. 2). The fruit is a capsule splitting along the septa (septicidal) (fig. 1), or between them (loculical), or a berry (fig. 6, 7); the seeds contain a small embryo in a copious fleshy or cartilaginous endosperm. Liliaceae is one of the larger orders of flowering plants containing about 2500 species in 200 genera; it is of world-wide distribution. The plants show great diversity in vegetative structure, which together with the character and mode of dehiscence of the flower afford a basis for the subdivision of the order into tribes, eleven of which are recognized. The following are the most important tribes.

Melanthioideae.—The plants have a rhizome or corm, and the fruit is a capsule. It contains 36 genera, many of which are not temperate and three are represented in Britain, viz. Tofoledia, an arctic and alpine genus of small herbs with a slender scape springing from a tuft of narrow evergreen leaves and racemose racemes of white flowers; Narthecium (bog-asphodel), herbs with a habit similar to Tofoledia, but with larger golden-yellow flowers; and Colchicum, with about 30 species including the meadow saffron or autumn crocus (C. autumnale). Colchicum illustrates the comb-development which is a rare characteristic of Liliaceae though common in the allied order Iridaceae; a corm is formed by swelling at the base of the axis (figs. 3, 4), and persists after the flowers and leaves have disappeared. The flowers have an ovary and Style of 3. The young corm produced laterally from the old one.

Asphodeloideae.—The plants generally have a rhizome bearing radical leaves, as in asphodel, rarely a stem with a tuft of leafy branches as in the yellow asphodel (Eriogonum) or bulb (Becnea). The flowers are borne in a terminal raceme, the anthers open introrsely and the fruit a three-celled capsule. It contains 6 genera. Asphodelus (asphodel) is a Mediterranean genus; Sisyrinchium, a slender herb with grassy radical leaves, is a native of west and southern Europe extending into south Ireland. Anthericum and Chlorophytum, herbs with radical once grass-like leaves and panicles bearing a more or less branched inflorescence of small generally white flowers, are widely spread in the tropics. Other genera are Fritillaria, native of China and Japan, cultivated in the open air in Britain; Hemerocallis, a small genus of central Europe and temperate Asia; H. fulva is known in gardens as the Yellow Flag or Yellow Perennial, a New Zealand genus to which belongs New Zealand flax, P. titinax, a useful fibre-plant; Kniphofia, South and East Africa, several species of which are cultivated; and Aloe. A small group of Australian genera closely approach the order Juncaceae in having small crowded flowers with a scarios.septum and a perianth without perianth; they include Xanthorrhoea (grass-tree or blackboy) and Kingia, arborescent plants with an erect woody stem crowned with a tuft of long stiff narrow leaves, from the centre of which rises a tall dense flower-head or a number of slender flower-heads; this group has been included in Juncaceae, from which it is doubtfully distinguished only by the absence of the long-stemmed stigmas which characterize the true rushes.

Aliiodeae. The plants grow from a bulb or short rhizome; the inflorescence is an apparent umbel formed of several short-stemmed monochasial cymes and surrounded by a pair of large bracts. It contains 22 genera, the largest of which Allium has about 250 species—7 British; A. stellatum or African lily, a well-known garden plant; in Gagea, a genus of small bulbous herbs found in most parts of Europe, the inflorescence is reduced to a few flowers or a single flower; G. lutea is a local and rare British plant.

Lilieae.—A large group with a terminal racemose inflorescence; the anthers open introrsely and the capsule is loculical. It contains 213 genera, several being represented in Britain. The typical genus Lilium and Fritillaria are widely distributed in the temperate regions of the northern hemisphere; F. meleagris, snake's head, is found in moor meadows in some of the southern and central English counties; Tadbe contains more than 50 species in Europe and temperate Asia, and is especially abundant in the dry districts of central Asia; Llloydia, a small slender alpine plant, widely distributed in the northern hemisphere, is found in the Snowdonia of Wales; Scilla (squill) is a large genus, chiefly in Europe and Asia—S. nutans is the blueflower; Gagea, and Colchicum (European, Africa, and west Asia) is closely allied to Scilla—O. umbellatum, star of Bethle- hem, is naturalized in Britain; Hyacinthus and Muscari are chiefly Mediterranean; M. race- mosum, grape hyacinth, occurs in sandy pastures in the eastern counties of England. To this group belong a number of tropical and sub-tropical genera such as Albuca, Urginea, Dracaena, Lachenalia, and others.

Dracaenoidae.—The plants generally have an erect stem with a crown of leaves which are often leathery; the anthers open introrsely and the fruit a berry or capsule. It contains 9 genera, several of which, such as Yucca (fig. 5), Dracaena and Cordyline include arborescent species in which the stem increases in thickness continually by a centrifugal formation of new tissue; an extreme example is Dracaena, the dragon-plant of Tenerife. Yucca and several allied genera are natives of the dry country of the southern and western United States and of Central America. Dracaena and the allied genus Cordyline occur in the warmer regions of South America; Yucca is a genus of the south-western United States. The relation between the pollination of many yuccas and the life of a moth (Prosula yuccastella); the flowers are open and scented at night when the female moth becomes active, first collecting a load of pollen and then depositing her eggs, generally in a different flower from that which has supplied the pollen. The eggs are deposited in the ovary-wall, usually just below an ovule; after each deposition the moth runs to the top of the pistil and thrusts some pollen into the opening of the stigma.
LILIENCRON

Development of larva and seed go on together, a few of the seeds serving as food for the insect, which when mature eats through the pericarp and drops to the ground, remaining dormant in its cocoon until the next season of flowering when it emerges as a moth. Asparagus contains about 100 species in the dryer warmer parts of the Old World; it has a short creeping rhizome, from which springs a slender, herbaceous or woody, often very much branched, erect or climbing stem, the ultimate branches of which are flattened or needle-like leaf-like structures (cladodes), the true leaves being reduced to scales or, in the climbers, forming short, hard or less recurved spines. Ruscus aculeatus (fig. 6) is butcher's broom, an evergreen shrub with flattened leaf-like cladodes, native in the southerly portion of England and Wales; the small flowers are unisexual and borne on the face of the cladode; the male contains three stamens, the filaments of which are united to form a short stout column on which are seated the diverging cells of the anthers; in the female the ovary is enveloped by a hairy staminode on which are borne three barren anthers. Polygonatum and Maianthemum are allied genera with a herbaceous leafy stem and, in the former axillary flowers, in the latter flowers in a terminal raceme; both occur rarely in woods in Britain; P. multiflorum is the well-known Solomon's seal of gardens (fig. 7), so called from the seal-like scars on the rhizome of stems of previous seasons, the hanging flowers of which contain no honey, but are visited by bees for the pollen. Convallaria is Lily of the valley; Aspidistra, native of the Himalayas, China and Japan, is a well-known pot plant; its flowers depart from the normal arrangement of the order in having the parts in fives (tetramerous). Paris, including the British Herb Paris (P. quadrifolia), has solitary tetra- to poly-merous flowers. fig. 7. Rhizome of Polygonatum multiflorum. A—Fig. 7—B. Bud of next year's aerial shoot. b, Scar of this year's, and c, d, e, scars of three preceding years' aerial shoots. terminating the short annual shoot which bears a whorl of four or more leaves below the flower; in this and in some species of the nearly allied genus Trillium (chiefly temperate North America) the flowers have a fetid smell, which together with the dark purple of the ovary and stigmas and frequently also of the stamens and petals, attracts carrion-loving flies, which alight on the stigma and then climb the anthers and become dusted with pollen; the pollen is then carried to the stigmas of another flower. Lauriaceae are shrubs or under-shrubs with erect or climbing branches and fruit a berry. Lapageria, a native of Chile, is a favourite greenhouse climber with fine bell-shaped flowers. Smilacaceae are climbing shrubs with broad net-veined leaves and small dioecious flowers in umbels springing from the leaf-axis; the fruit is a berry. They climb by means of tendrils, which are stipular structures arising from the leaf-sheath. Smilax is a characteristic tropical genus containing about 200 species; the dried roots of some species are the true sarsaparilla. The two tribes Ophiopogonoideae and Alectroideae are often included in a distinct order, Rhododendraceae. The plants have a short rhizome of small racemose, or common, flowers, and having the same ovary, ovary, and style, which are characterized by the ovary being somewhat inferior. They contain a few genera chiefly old world tropical and subtropical. The leaves of species Sansevieria yield a valuable fibre.

Liliaceae may be regarded as the typical order of the series Liliflorae. It resembles Juncaceae in the general plan of the flower, which, however, has become much more elaborate and varied in the form and colour of its perianth in association with transmission of pollen by insect agency; a link between the two is found in the group of Australian genera referred above under Asphodeloidae. The tribe Ophiopogonoideae, with its tendency to an inferior ovary, suggests an affinity with the Amaryllidaceae which resemble Liliaceae in habit and in the horizontal plan of the flower, but have an inferior ovary. The tribe Smilacoidae, shrubby climbers with net-veined leaves and small unisexual flowers, bears much the same relationship to the order as a whole as does the order Dioscoreaceae, which have a similar habit, but flowers with an inferior ovary, to the Amaryllidaceae.

LILIENCRON, DETLEV VON (1844-1900), German poet and novelist, was born at Kiel on the 3rd of June 1844. He entered the army and took part in the campaigns of 1866 and 1870-71, in both of which he was wounded. He retired with the rank of captain and spent some time in America, afterwards settling at Kellinghusen in Holstein, where he remained till 1887. After some time at Munich, he settled in Altona and then at Altrahlstedt, near Hamburg. He died in July 1900. He first attracted attention by the volume of poems, Adjutantenwirte und andere Gedichte (1883), which was followed by several unsuccessful dramas, a volume of short stories, Eine Sommerschlacht (1886), and a novel Breide Hummelsbähtel (1887). Other collections of short stories appeared under the titles Unter Flatternden Fähnen (1888), Der Mäuler (1890), Krieg und Frieden (1891); of lyric
poetry in 1889, 1890 (Der Heidegänger und andere Gedichte), 1893, and 1903 (Bunte Beute). Interesting, too, is the humorous epic Porgfred (1896; 2nd ed. 1904). Liliencron is one of the most eminent of recent German lyric poets; his Adjutantenlied, with its fresh original note, broke with the well-worn literary conventions which had been handed down from the middle of the century. Liliencron’s work is, however, somewhat unequal, and he lacks the sustained power which makes the successful prose writer.

Liliencron’s Sämtliche Werke have been published in 14 vols. (1904–1905); his Gedichte having been previously collected in four volumes under the titles Kampf und Spiele, Kampf und Ziele, Nebel und Sonne, and Bunte Beute (1897–1903). See O. J. Bierbaum, D. von Liliencron (1892); H. Greina, Liliencron, eine literarhistorische Würdigung (1896); F. Oppenheimer, D. von Liliencron (1898).

LILITH (Heb. לילית; “night”; hence “night-monster”), a female demon of Jewish folk-lore, equivalent to the English vampire. The personality and name are derived from a Babylonian-Assyrian demon Lilith or Lutu. Lilith was believed to have a special power for evil over children. The superstition was extended to a cult surviving among some Jews even as late as the 7th century A.D. In the Rabbinical literature Lilith becomes the first wife of Adam, but flies away from him and becomes a demon.

LILLE, a city of northern France, capital of the department of Nord, 154 m. N. by E. of Paris on the Northern railway. Pop. (1906) 106,624. Lille is situated in a low fertile plain on the right bank of the Deûle in a rich agricultural and industrial region of which it is the centre. It is a first-class fortress and headquarters of the I. army corps, and has an enceinte and a pentagonal citadel, one of Vauban's finest works, situated to the west of the town, from which it is divided by the Deûle. The modern fortifications comprise twenty detached forts and batteries, the perimeter of the defences being about 20 m. Before 1858 the town, fortified by Vauban about 1668, occupied an elliptical area of about 2500 yds. by 1300, with a church of Notre-Dame de la Treille in the centre, but the ramparts on the south side have been demolished and the ditches filled up, their place being now occupied by the great Boulevard de la Liberté, which extends in a straight line from the goods station of the railway to the citadel. At the S.E. end of this boulevard are grouped the majority of the numerous educational establishments of the city. The new enceinte encloses the old quarters of Esquermes, Wazemmes and Moulin-Lille, the area of the town being thus more than doubled. In the new quarters fine boulevards and handsome squares, such as Place Roger Salengro, are in pleasant contrast with the sombre aspect of the old town. The district of St André to the north, the only elegant part of the old town, is the residence of the aristocracy. Outside the enceinte populous suburbs surround the city on every side. The demolition of the fortifications on the north and east of the city, which is continued in those directions by the great suburbs of La Madeleine, St Maurice and Fives, must accelerate its expansion towards Roubaix and Tourcoing. At the demolition of the southern fortifications, the Paris gate, a triumphal arch erected in 1682 in honour of Louis XIV., after the conquest of Flanders, was preserved. On the east the Ghent and Roubaix gates, built in the Renaissance style, with bricks of different colours, date from 1617 and 1622, the time of the Spanish domination. On the south side the Noble-Tour is a relic of the medieval ramparts. The present enceinte is pierced by numerous gates, including water gates for the canal of the Deûle and for the Arnoisonne, which extends into a marsh in the south-west corner of the town. The citadel, which contains the barracks and arsenal, is surrounded by public gardens. The more interesting buildings are in the old town, where, in the Grande Place and Rue Faidherbe, its animation is concentrated. St. Maurice, a church in the late Gothic style, dates in its oldest portions from the 15th century, and was restored in 1872; Ste. Cathérine belongs to the 15th, 16th and 18th centuries, St André to the first years of the 18th century, and Ste Madeleine to the last half of the 17th century; all possess valuable pictures, but St Maurice alone, with nave and double aisles, and elegant modern spire, is architecturally notable. Notre-Dame de la Treille, begun in 1835, in the style of the 15th century, possesses an ancient statue of the Virgin which is the object of a well-known pilgrimage. Of the civil buildings the Bourse (17th century) built round a courtyard in which stands a bronze statue of Napoleon I., the Hôtel d'Aigremont, the Hôtel Gentil and other houses are in the Flemish style; the Hôtel de Ville, dating in the main from the middle of the 16th century, preserves a portion of a palace built by Philip the Good, duke of Burgundy, in the 15th century. The prefeture, the Palais des Beaux-Arts, the law courthouses, the school of arts and crafts, and the Lycée Faidherbe are imposing modern buildings. In the middle of the Grande Place stands a column, erected in 1848, commemorating the defence of the town in 1792 (see below), and there are also statues to Generals L. C. Faidherbe and F. O. de Négrès, and busts of Louis Pasteur and the popular poet and singer A. Desrousseaux. The Palais des Beaux-Arts contains a museum and picture galleries, among the richest in France, as well as a unique collection of original designs of the great masters bequeathed to Lille by J. B. Wicar, and including a celebrated wax model of a girl's head usually attributed to some Italian artist of the 16th century. The city also possesses a commercial and colonial museum, an industrial museum, a fine collection of departmental and municipal archives, the museum of the Institute of Natural Sciences and a library containing many valuable manuscripts, housed at the Hôtel de Ville. The large military hospital, once a Jesuit college, is one of several similar institutions.

Lille is the seat of a prefect and has tribunals of first instance and of commerce, a board of trade arbitrators, a chamber of commerce and a branch of the Bank of France. It is the centre of an académie (educational division) and has a university with faculties of laws, letters, science and medicine and pharmacy, together with a Catholic institute comprising faculties of theology, law, medicine and pharmacy, letters, science, a technical school, and a department of social and political science. Secondary education is given at the Lycée Faidherbe, and the Lycée Fénelon (for girls), a higher school of commerce, a national technical school and other establishments; these must be added schools of music and fine arts, and the Industrial and Pasteur Institutes.

The industries, which are carried on in the new quarters of the town and in the suburbs, are of great variety and importance. In the first rank comes the spinning of flax and the weaving of linen. Besides the manufacture of linen, damask, ticking and flax for the navy, there are numerous firms and establishments producing linen of the highest quality. The spinning of flax thread for sewing and lace-making is specially carried on with Lille. The manufacture of woollen fabrics and cotton-spinning and the making of cotton-twist of fine quality are also carried on. There are important printing establishments, state factories for the manufacture of tobacco and the refining of saltpetre and very numerous breweries, while chemical, oil, white lead and sugar-works, distilleries, bleaching-grounds, dye-works, machinery and boiler works and cabinet-making occupy many thousands of workmen. Plant for sugar-works and distilleries, military stores, steam-engines, locomotives, and bridges of all kinds are produced by the company of Fives-Lille. Lille is one of the most important junctions of the Northern railway, and the Deûle canal affords communication with neighbouring ports and with Belgium. Trade is chiefly in the raw material and machinery for its industries, in the products thereof, and in the wheat and other agricultural products of the surrounding district.

Lille (LIt) is said to date its origin from the time of Count Baldwin IV. of Flanders, who in 1030 surrounded with walls a little town which had arisen around the castle of Buc. In the first half of the 13th century, the town, which had developed rapidly, obtained communal privileges. Destroyed by Philip Augustus in 1213, it was rebuilt by Joanna of Constantinople, countess of Flanders, but besieged and retaken by Philip the Fair in 1297. After having taken part with the Flemings against the king of France, it was ceded to the latter in 1322. In 1360 Charles V., king of France, gave it to Louis de Male, who
transmitted his rights to his daughter Margaret, wife of Philip the Bold, duke of Burgundy. Under the Burgundian rule Lille enjoyed great prosperity; its merchants were at the head of the London Hansa. Philip the Good made it his residence, and within its walls held the first chapters of the order of the Golden Fleece. With the rest of Flanders it passed from the dukes of Burgundy to Austria and then to Spain. After the death of Philip IV. of Spain, Louis XIV. reclaimed the territory and besieged Lille in 1667. He forced it to capitulate, but preserved all its laws, customs, privileges and liberties. In 1708, after an heroic resistance, it surrendered to Prince Eugene and the duke of Marlborough. The treaty of Utrecht restored it to France. In 1792 the Austrians bombarded it for nine days and nights without intermission, but had ultimately to raise the siege.

See E. Vanhende, Lille et ses institutions communales de 620 à 1804 (Lille, 1888).

LILLOBURDORO, or LILLOBURDERO, the name of a song popular at the end of the 17th century, especially among the army and supporters of William III. in the war in Ireland during the revolution of 1688. The tune appears to have been much older, and was sung to an Irish nursery song at the beginning of the 18th century, and the attribution of Henry Purcell is based on the very slight ground that it was published in Music's Handmaid, 1689, as "A new Irish Tune" by Henry Purcell. It was also a marching tune familiar to soldiers. The doggerel verses have generally been assigned to Thomas Wharton, and deal with the administration of Tielbot, earl of Tyrconnel, appointed by James as his lieutenant in Ireland in 1687. The refrain of the song lilloberdo bullon a la gave the title of the song. Macaulay calls the song "The verses and the tune catch the fancy of the nation. From one end of England to the other all classes were singing this idle rhyme." Though Wharton claimed he had "sung a king out of three kingdoms" and Burnet says "perhaps never had so slight a thing so great an effect" the success of the song was "the effect, and not the cause of that excited state of public feeling which produced the revolution." (Macaulay, Hist. of Eng. chap. ix).

LILLO, GEORGE (1603–1739), English dramatist, son of a Dutch jeweller, was born in London on the 4th of February 1603. He was brought up to his father's trade and was for many years a partner in the business. His first piece, Silvia, or the Country Burial, was a ballad opera produced at Lincoln's Inn Fields in November 1730. On the 22nd of June 1731 his domestic tragedy, The Merchant, renamed later The London Merchant, or the History of George Barnwell, was produced by Theophilus Cibber and his company at Drury Lane. The piece is written in prose, which is not free from passages which are really blank verse, and is founded on "An excellent ballad of George Barnwell, an apprentice of London who...thrice robbed his master, and murdered his uncle in Ludlow." In line with the tradition that the characters of every tragedy must not be derived from people of high rank and fortune he went back to the Elizabethan passion of the Yorkshire Tragedy is a type. The obtrusively moral purpose of this play places it in the same literary category as the novels of Richardson. Scoffing critics called it, with reason, a "Newgate tragedy," but it proved extremely popular on the stage. It was regularly acted for many years at holiday seasons for the moral benefit of the apprentices. The last act contained a scene, generally omitted on the London stage, in which the gallows actually figured. In 1734 Lillo celebrated the marriage of the Princess Anne with William IV. of Orange in Britanniia and Batavia, a masque. A second tragedy, The Christian Hero, was produced at Drury Lane on the 13th of January 1735. It is based on the story of Scanderbeg, the Albanian chieftain, a life of whom is printed with the play. Thomas Whincoop (d. 1730) wrote a piece on the same subject, printed posthumously in 1747. Both Lillo and William Havard also wrote a dramatic version of the story, were accused of plagiarizing Whincoop's Scanderbeg. Another murder-drama, Fatal Curiosity, in which an old couple murder an unknown guest, who proves to be their own son, was based on a tragedy at Boehlerland Farm near Penryn in 1688. It was produced by Henry Fielding at the Little Theatre in the Haymarket in 1736, but with small success. In the next year Fielding tackled it on his own Historical Register for 1736, and it was received more kindly. It was revised by George Colman the elder in 1782, by Henry Mackenzie in 1784, &c. Lillo also wrote an adaptation of the Shakespearean play of Pericles, Prince of Tyre, with the title Marina (Covent Garden, August 1st, 1738); and a tragedy, Elmerick, or Justice Triumphant (produced posthumously, Drury Lane, February 23rd, 1749). The statement made in the preface to this play that Lillo died in poverty seems unfounded. His death took place on the 3rd of September 1739. He left an unfinished version of Arden of Feversham, which was completed by Dr John Hoadly and produced in 1759. Lillo's reputation proved short-lived. He has nevertheless a certain cosmopolitan importance, for the influence of George Barnwell can be traced in the sentimental drama of both France and Germany.

See Lillo's Dramatic Works with Memoirs of the Author by Thomas Davies (reprinted by Lowndes, 1810); Cibber's Lives of the Poets, Some of the English Stage; Aloys Brandl, "Zu Lillo's Kaufmann in London," in Vier Jahrhunderte Theatergeschichte (Weimar, 1890, vol. iii.); Leopold Hoffmann, George Lillo (Marburg, 1888); Paul von Hofmann-Wellenhof, Shakespeare's Pericles and George Lillo's Marina (Viehoz's Gesch. d. engl. Theater, 1883). There is a novel founded on Lillo's play, Barnwell (1867), by T. S. Surt, and in "George de Barnwell" (Novels by Eminent Hands) Thackeray parodies Bulwer-Lytton's Eugene Aram.

LILLY, WILLIAM (1602–1661), English astrologer, was born in 1602 at Diseworth in Leicestershire, his family having been settled as yeomen in the place for "many ages." He received a tolerably good classical education at the school of Ashby-de-la-Zouche, but he was not, and perhaps have some significance in reference to his after career, that matter "never taught logic." In his eighteenth year, his father having fallen into great poverty, he went to London and was employed in attendance on an old citizen and his wife. His master, at his death in 1627, left him an annuity of £20; and, Lilly having soon afterwards married the widow, she, dying in 1633, left him property to the value of about £600. He now began to dabble in astrology, reading all the books on the subject he could fall in with, and occasionally trying his hand at unravelling mysteries by means of his art. The years 1642 and 1643 were devoted to a careful revision of all his previous reading, and in particular having lighted on Valentine Nalboad's Commentary on Alchobitus, he "seriously studied him and found him to be the profoundest author he ever met with." About the same time he tells us that he "did carefully take notice of every grand action betwixt king and parliament, and did first then incline to believe that as all sublunary affairs depend on superior causes, so there was a
possibility of discovering them by the configurations of the superior bodies." And, having thereupon "made some essays," he "found encouragement to proceed further, and ultimately framed to himself that method which he ever afterwards followed." He then began to issue his prophetic almanacs and other works, which met with serious attention from some of the most prominent members of the Long Parliament. If we may believe himself, Lilly lived on friendly and almost intimate terms with Bulstrode Whitlock, Lenthall the speaker, Sir Philip Stapleton, Elias Ashmole and others. Even Selden seems to have given him some countenance, and probably the chief difference between him and the mass of the community at the time was that, while others believed in the general truth of astrology, he ventured to specify the future events to which its calculations pointed. Even from his own account of himself, however, it is evident that he did not trust implicitly to the indications given by the aspects of the heavens, but like more vulgar fortune-tellers kept his eyes and ears open for any information which might make his predictions safe. It appears that he had correspondents both at home and in foreign parts to keep him conversant with the probable current of affairs. Not a few of his exploits indicate rather the quality of a clever police detective than of a profound astrologer. After the Restoration he very quickly fell into disrepute. His sympathy with the parliament, which his predictions had generally shown, was not calculated to bring him into royal favour. He came under the lash of Butler, who, making allowance for some satiric exaggeration, has given in the character of Sidrophel a probably not very incorrect picture of the man; and, having by this time amassed a tolerable fortune, he bought a small estate at Hersham in Surrey, to which he retired, and where he diverted the exercise of his peculiar talents to the practice of medicine. He died in 1684.

Lilly's life of himself, published after his death, is still worth looking into as a remarkable record of credulity. So lately as 1852 a prominent London publisher put forth a new edition of Lilly's *Introduction to Astrology*, "with numerous emendations adapted to the temperate climate, and to the spirit of the age."

**LILIANA—LILY**

**LILIANA—LILY**

with much information on the cultivation of lilies and the diseases to which they are subject, will be found in the report of the Conference on Lilies, in the *Journal of the Royal Horticultural Society*, 1901. The new species include a number discovered in central and western China by Dr Augustine Henry and other collectors; also several from Japan and California.

The structure of the flower represents the simple type of monocotyledons, consisting of two whorls of petals, of three free parts each, six free stamens, and a consolidated pistil of three carpels, ripening into a three-valved capsule containing many winged seeds. In form, the flower assumes three types: trumpet-shaped, with a more or less elongated tube, *e.g.* *L. longiflorum* and *L. candidum*; an open form with spreading perianth leaves, *e.g.* *L. auratum*; or assuming a pendulous habit, with the tips strongly reflexed, *e.g.* the martagon type. All have scaly bulbs, which in three west American species, as *L. umbolithus*, are remarkable for being somewhat intermediate between a bulb and a creeping rhizome. *L. bulbiferum* and its allies produce aerial reproductive bulbs in the axils of the leaves.

The bulbs of several species are eaten, such as of *L. avenaceum* in Kamchatka, of *L. Martagon* by the Cossacks, and of *L. Liliaceae*, the “liger lily,” in China and Japan. Medicinal uses were ascribed to the species, but none appear to have any marked properties in this respect.

The white lily, *L. candidum*, the λουσος of the Greeks, was one of the commonest garden flowers of antiquity, appearing in the poets from Homer downwards side by side with the rose and the lily. According to Hellen, roses and lilies entered Greece from the east by way of Phrygia, Thrace, and Macedonia (*Kulturpfanzen und Hausthiere*, 3rd ed., p. 217). The word λουσος itself, from which *lilium* is derived by assimilation of consonants, appears to be Eranian (*Ibid.* p. 527), and according to ancient etymologists (*Lagarde*, *Ges. Abh.* p. 277) the town of Susa was connected with the Persian name of *lilies* *salan* (*Gr. olos*, Heb. *shošhan*). Mythologically the white lily, *Rosa Lutea*, was said to have sprung from the milk of Hera. As the plant of purity it was contrasted with the rose of Aphrodite. The word *rose*, on the other hand, included red and purple lilies, *Pinn. H. N. xxx. 5* (11, 12), the red lily being best known in Syria and Judaea (*Phaselis*). This perhaps is the "red lily of Constantinople" of *L. chalcedonicum*. The lily of the Old Testament (*shošhan*) may be conjectured to be a red lily from *Lilium* in Cant. vi. 2, though the allusion is to the fragrance rather than the colour of the lips, in which case the white lily must be thought of. The "lilies of the field," Matt. vi. 28, are *cynips*, and the comparison of their beauty with royal robes suggests their identification with the red *Lilium* of Pliny. Lilies, however, are not a conspicuous feature in the flora of Palestine, and the red anemone (*Anemone coronaria*), with which all the hill-sides of Galilee are dotted in the spring, is perhaps more likely to have suggested the figure. For the lily in the pharmacopoeia of the ancients see *Adams' Paul. Agrestina*, iii. 196. It was used in unguents and against the bites of snakes, &c. In the middle ages the flower continued to be common and was taken as the symbol of heavenly purity.

The lilies of France are said to have been originally three lanced-heads. Lily of the valley, *Convallaria majalis*, belongs to a different tribe (*Asparagidæ*) of the same order. It grows wild in woods in Britain, and is also found in parts of northern Asia and the Appalachian Mountains of North America. The leaves and flower-scapes spring from an underground creeping stem. The small pendulous bell-shaped flowers contain no honey but are visited by bees for the pollen.

The word "lily" is loosely used in connexion with many plants which are not really lilies at all, but belong to genera which are...
quite distinct botanically. Thus, the Lent lily is Narcissus Pseudo-narcissus; the African lily is Agapanthus umbellatus; the Belladonna lily is Amaryllis Belladonna (q.v.); the Jacobaea lily is Sprekelia formosissima; the Mariposa lily is Calochortus; the lily of the Incas is Alstroemeria peregrina; St. Bernard’s lily is Anthericum Liliago; St. Bruno’s lily is Anthericum (or Paradisi) Liliastrium; the water lily is Nymphaea alba; the Arum lily is A. Richardiana africana; and there are many others.

The true lilys are so numerous and varied that no general cultural instructions will be alike suitable to all. Some species, as L. Marigott, candisum, chaledonicum, Szkolichianum (or colchicum); bulbiferum, crocus, Henry, pomponium—the ‘Turk’s cap’ lily; and others, will grow in almost any good garden soil, and succeed admirably in loam of a rather heavy character, and dislike too much peat. But a compost of peat, loam and leaf-soil suits L. auratum, Brownii, concolor, elegans, giganteum, japonicum, longiflorum, Gymnadenia or L. liriginnas well, and a larger proportion of peat is indispensable for the beautiful American L. superbum and cardenase.

The margin of rhododendron beds, where there are sheltered recesses amongst the plants, suits many of the more delicate species well, partial shade moderately shady place out-doors to remain till they flower, when they may be removed to the greenhouse. This treatment suits the gorgeous L. auratum, the splendid varieties of L. speciosum (lancifolium) and also the chaste-flowering trumpet-tubed L. longiflorum and L. candidum. These are the most popular lilies in the greenhouse, and speciosum are now retarded in refrigerators and taken out in batches for greenhouse work as required.

Diseases.—Lilies are, under certain conditions favourable to the development of the disease, subject to attacks of both fungous and bacterial fungi. The most destructive is Botrytis cinerea which forms orange-brown or buff specks on the stems, pedicels, leaves and flower-buds, which increase in size and become covered with a delicate grey or brownish spore. The lily is also attacked by the common golden scab (Rhizopus nicosus) which turns the bulbs jet black, the loose scales peeling away when touched, the bulbs forming small black hard bodies embedded in the flesh. For prevention, the surface soil covering bulbs should be removed every autumn and replaced by soil mixed with kainit; manure for mulching should also be mixed with kainit, which acts as a steriliser. If the fungus appears on the foliage spray with potassium sulphide solution (2 oz. in 3 gallons of water). Uromyces erythrorni, a rust, sometimes causes considerable injury to the foliage of species of Lilium and other bulbous plants, forming large discoloured blotches on the leaves. The diseased stems should be removed and burned before the leaves fall; as the bulb is not attacked the plant will start growth next season free from disease. Another species, Uromyces nicosus is sometimes of extensive destruction of bulbs. The fungus attacks injured roots and afterwards passes into the bulb which becomes brown and finally rots. The fungus hibernates in the soil and enters through brown or injured roots. Remedy is the same as for the previous one, having the bulbs that the roots are injured as little as possible. An excellent dressing material for dormant buds is coarsely crushed wood-charcoal to which has been added a sprinkling of flowers of sulphur. This prevents infection from outside and also destroys the spores or fungus mycelium which may have been packed away along with the bulbs.

When cultivated in greenhouses liliums are subject to attack from aphides (green fly) in the early stages of growth. The pests can be kept in check by syringing with nicotine, soft-soap and quassia solutions, or by ‘vapourising’ two or three evenings in succession, afterwards syringing the plants with clear tepid water.

LILYE, or LILY, WILLIAM (c. 1468-1522), English scholar, was born at Oldham in Hampshire. He entered the university of Oxford in 1486, and after graduating in arts went on a pilgrimage to Jerusalem. On his return he put in at Rhodes, which was still occupied by the knights of St John, under whose protection many Greeks had taken refuge after the capture of Constantinople by the Turks. He then went on to Italy, where he attended the lectures of Sulpitius Verulanus and Pompionius Laetus at Rome, and of Eugnatius at Venice. After his return he settled in London (where he became intimate with Thomas More) as a private teacher of grammar, and is believed to have been the first who taught Greek in that city. In 1510 Collet, dean of St Paul’s, who was then founding the school which afterwards became famous, appointed Lilie the first high master. He died of the plague on the 25th of February 1522.

Lilie is famous not only as one of the pioneers of Greek learning, but as one of the joint-authors of a book, familiar to many generations of students during the 19th century, the old Eton Latin grammar. The Brevisissima institutio, a sketch by Colet, corrected by Erasmus and worked upon by Lilie, contains two portions, the author of the first part being John Lyly, of whom it is supposed that Lilie only adapted it. Besides the Brevisissima institutio, Lilie wrote a variety of Latin pieces both in prose and verse. Some of the latter are printed along with the Latin verses of Sir Thomas More in Fregmogiam curia regis. Lyttes magnum librum. Lilie’s Latin volume of Latin verse (Ambassadon a Guilelmi Hormanum, 1551) is directed against a rival schoolmaster and grammarian, Robert Whittington, who had ‘under the feigned name of Bossu, most successfully impugned Lilie’s text in his Latin verse.

See the sketch of Lilie’s life by his son George, canon of St Paul’s, written for Paulus Jovius, who was collecting for his history the lives of the learned men of Great Britain; and the article by J. H. Furnivall, formerly sur-master of St Paul’s School, in the Dictionary of National Biography.

LIMA, a city and the county-seat of Allen county, Ohio, U.S.A., on the Ottawa river, about 70 m. S.S.W. of Toledo, Pop. (1890) 15,981; (1900) 21,723, of whom 1457 were
LIMA

689

foreign-born and 731 were negroes; (1910 census) 39,508. It is
served by the Pennsylvania (Pittsburgh, Ft. Wayne & Chicago
division), the Erie, the Cincinnati, Hamilton & Dayton, the Lake
Erie & Western, the Detroit, Toledo & Ironton railways, and by
six interurban electric lines. Immediately N. of the city is a
state asylum for the insane. Lima has a Carnegie library, a
city hospital and a public park of 100 acres. Among the principal
buildings are the county court house, a masonic temple, an
Elks' home and a soldiers' and sailors' memorial building.
Lima College was conducted here from 1893 to 1908. Lima
is situated in the centre of the great northwest-Indian oil-field (Trenton
limestone of the Ordovician system) of Ohio, which was first
developed in 1885; the product of the Lima district was
20,575,138 barrels in 1896, 15,877,730 barrels in 1902 and
6,748,576 barrels in 1908. The city is a headquarters of the
Standard Oil Company, and the refining of petroleum is one of the
principal industries. The total value of the factory product in
1905 was $3,155,856, an increase of 31.1% over that in 1900.
Lima contains railway shops of the Cincinnati, Hamilton &
Dayton and the Lake Erie & Western railways. The city has
a large wholesale and jobbing trade. The municipality owns and
operates the water-works. Lima was laid out in 1831, and
was first organised as a city under the auspices of town
LIMA, a coast department of central Peru, bounded N. by
Ancachs, E. by Junin and Huancavelica, S. by Ica and W.
by the Pacific Ocean. Pop. (1906 estimate) 250,000; area
13,314 sq. m. The eastern boundary follows the crests of the
Western Cordillera, which gives to the department the western
slopes of this chain with the drainage basins of the rivers Huaura,
Chancay, Chillon, Rimac, Lima, Mala and Cañete. Although
the department forms part of the rainless region, these rivers,
fed from the snows of the high Andes, provide water for the
irrigation of large areas devoted to the raising of cotton, sugar,
sorghum, Indian corn, alfalfa, potatoes, grapes and olives. The
sugar estates of the Cañete are among the best in Peru and are
served by a narrow gauge railway terminating at the small
port of Cerro Azul. Indian corn is grown in Chancay and other
northern valleys, and is chiefly used, together with alfalfa and
barley, in fattening swine for lard. The mineral resources are
not important, though gold washings in the Cañete valley have
been mined since early colonial times. One of the
important industrial establishments in the department is the melting
works at Casapalca, on the Oroya railway, in the Rimac valley,
which receives ores from neighbouring mines of the district of
Huaura. The department is crossed from S.W. to N.E. by
the Oroya railway, and several short lines run from the city of
Lima to neighbouring towns. Besides Lima (q.v.) the principal
towns are Huacho, Cañete (port), Canta, Yauyo, Chorrillos,
Mirafloros and Barranco—the last three being summer residences
for the people of the capital, with variable populations of 15,000,
6000 and 5000 respectively. About 15 m. S. of Lima, near
the mouth of the river, are the celebrated ruins of Pachacamac,
which are believed to antedate the occupation of this region
by the Incas.

LIMA, the principal city and the capital of Peru and of
the department and province of Lima, on the left bank of the river
Rimac, 73 m. above its mouth and the same distance to N.
by its seaport Callao, in 12° 2' 43" S., 77° 3' 36" W. Pop. (1906
estimate) 140,000, of whom a large proportion is of negro
descent, and a considerable number of foreign birth. The city
is about 48 ft. above sea-level, and stands on an arid plain,
which rises gently toward the S., and consists chiefly of
the Cerros de San Jeronimo (2405 ft.) and San Cristobal (1411 ft.)
ons the N. and a short range of low hills, called the Cerros de San
Bartolomé, on the E. The surrounding region is arid, like all
this part of the Pacific coast, but through irrigation large areas
have been brought under cultivation, especially along the water-
courses. The Rimac has its source about 105 m. N.E. of Lima
and is fed by the melting snows of the higher Andes. It is an
insignificant stream in winter and a raging torrent in summer.
Its tributaries are all of the same character, except the Rio Surco,
which rises near Chorrillos and flowing northward joins the
Rimac a few miles above the city. These, with the Rio Lurin,
which enters the Pacific a short distance S. of Chorrillos, provide
water for irrigating the districts near Lima. The climate varies
somewhat from that of the arid coast in general, in having a
winter of four months characterized by cloudy skies, dense fogs
and sometimes a drizzling rain. The air in this season is raw
and chilly. For the rest of the year the sky is clear and the air
dry. The mean temperature for the year is 66° F., the winter
minimum being 59° and the summer maximum 78°.
The older part of Lima was laid out and built with mathe-
atical regularity, the streets crossing each other at right
angles and enclosing square areas, called manzanas, of nearly
uniform size. Later extensions, however, did not follow this
plan strictly, and there is some variation from the straight line
in the streets and also in the size and shape of the manzanas.
The streets are roughly paved with cobble stones and lighted
with gas or electricity. A broad boulevard of modern con-
struction partly encircles the city, occupying the site of the old
brick walls (18 to 20 ft. high, 10 to 12 ft. thick at the base and
9 ft. at the top) which were constructed in 1585 by a Fleming
named Pedro Ramon, and were razed by Henry Meiggs during
the administration of President Balta. The water-supply is
generated by the Riachuelo de los Ríos, which is conveyed,
impounded, and carried on the surface, now passes into a system of subterranean sewers. The streets and suburbs of Lima are served by tramways,
mostly worked by electric traction. The suburban lines include
two to Callao, one to Magdalena, and one to Mirafloros and
Chorrillos. On the north side of the river is the suburb or
district of San Lazaro, shut in by the encircling hills and occupied
in great part by the poorer classes. The principal squares are
the Plaza Mayor, Plaza Bolívar (formerly P. de la Inquisicion
and P. de la Independencia), Plaza de la Exposicion, and Plaza
del Acho, on the north side of the river, the site of the bull-ring.
The public gardens, connected with the Exposition palace on
the S. side of the city, and the Paseo Colon are popular among
the Limesos as pleasure resorts. The long Paseo Colon, with
its parallel drives and paths, is ornamented with trees, shrubbery
and statues, notably the Columbus statue, a group in marble
expressing a golden bronze figure of Victory, stands where the Callao road crosses the Boulevard. Most
conspicuous among the public buildings of Lima is the cathedral,
whose twin towers and broad façade look down upon the Plaza
Mayor. Its foundation stone was laid in 1535 but the cathedral
was not consecrated until 1625. The great earthquake of
1746 reduced it to a mass of ruins, but it was reconstructed by
1758, practically, as it now stands. It has double aisles and ten
nave-like tribunes, each terminated by a chapel. The nave is
narrower than the other parts of the church, the remains of
Francisco Pizarro, the conqueror of Peru. Also facing the same
square are the archbishoppal and government palaces; the
latter formerly the palace of the viceroys. The interesting
cases of the Inquisition, whose tribunals rivalled those of Madrid
in cruelty, faces upon Plaza Bolivar, as also the old University
of San Marcos, which dates from 1551 and has faculties of theology,
law, medicine, philosophy and literature, mathematics,
and administrative and political economy. The churches and
convents of Lima are richly endowed as a rule, and some of the
churches represent a very large expenditure of money. The
LIMA

convent of San Francisco, near the Plaza Mayor, is the largest monastic establishment in Lima and contains some very fine carvings. Its church is the finest in the city after the cathedral. Other noteworthy churches are those of the convents of Santo Domingo, La Merced and San Augustin. There are a number of conventual establishments (for both sexes), which, with their chapels, and with the smaller churches, retreats, sanctuaries, &c., make up a total of 66 institutions devoted to religious observances. An attractive, and perhaps the most popular public building in Lima is the Exposition palace on the plaza and in the public gardens of the same name, on the south side of the city. It dates from 1872; its halls are used for important public assemblies, and its upper floor is occupied by the National Historical Institute, its museum and the gallery of historical pictures, and by the important diocesan libraries. Other noteworthy buildings and institutions are the National Library, the Lima Geographical Society, founded in 1888; the Mint, which dates from 1565 and is considered to be one of the best in South America; the great bull-ring of the Plaza del Acho, which dates from 1768 and can seat 8000 spectators; the Concepcion market; a modern penitentiary; and various charitable institutions. In addition to the old university on the Plaza Bolivar, which has been modernized and greatly improved, Lima has a school of engineers and mines (founded 1876), the old college of San Carlos, a normal school (founded 1905), a school of agriculture (situated outside the city limits and founded in 1902), two schools for girls under the direction of religious sisters, an episcopal seminary called the Seminario Conciliar de Santo Toribio, and a school of arts and trades in which elementary technical instruction is given. Under the old régime, primary instruction was almost neglected, but the 20th century brought about important changes in this respect. In addition to the primary schools, the government maintains free night schools for workmen.

The residences of the city are for the most part of one storey and have mud walls supported by a wooden framework which enclose open spaces, called patios, around which the living rooms are ranged. The better class of dwellings have two floors and are sometimes built of brick. A projecting, lattice-enclosed window for the use of women is a prominent feature of the larger houses and gives a picturesque effect to the streets.

Manufacturing has had some considerable development since the closing years of the 19th century; the most important manufactories are established outside the city limits; they produce cotton and woolen textiles, the products of the sugar estate, chocolate, coca, cigars and cigarettes, beer, artificial liquors, cotton-seed oil, hats, macaroni, matches, paper, soap and candles. The commercial interests of the city are important, a large part of the interior being supplied from this point. With its port Callao the city is connected by two steam railways, one of which was built as early as 1848; one railway runs northward to Ancón, and another, the famous Oroya line, runs inland 130 m., crossing the Western Cordillera at an elevation of 15,645 ft. above sea-level, with branches to Cerro de Pasco and Huari. The export trade properly belongs to Callao, though often credited to Lima. The Limeños are an intelligent, hospitable, pleasure-loving people, and the many attractive features of their city make it a favorite resort for foreign tourists.

Lima was founded on the 18th of January 1535 by Francisco Pizarro, who named it Ciudad de los Reyes (City of the Kings) in honour of the emperor Charles V. and Doña Juana his mother, or, according to some authorities, in commemoration of the Feast of the Epiphany (6th January) when its site is said to have been selected. The name soon after gave place to that of Lima, a Spanish corruption of the Quechua word Rímac. In 1541 Lima was made an episcopal see, which in 1545 was raised to a metropolitan see. Under Spanish rule, Lima was the principal city of South America, and for a time was the entrepôt for all the Pacific coast colonies south of Panama. It became very prosperous during this period, though often visited by destructive earthquakes, the most disastrous of which was that of the 28th of October 1746, when the cathedral and the greater part of the city were reduced to ruins, many lives were lost, and the port of Callao was destroyed. Lima was not materially affected by the military operations of the war of independence until 1821, when a small army of Argentines and Chileans under General Martin invested the city, and took possession of it on the 12th of July upon the withdrawal of the Spanish forces. San Martin was proclaimed the protector of Peru as a free state on the 28th of July, but resigned that office on the 20th of September 1822 to avoid a fratricidal struggle with Bolivar. In March 1828 Lima was again visited by a destructive earthquake, and in 1834-1835 an epidemic of yellow fever carried off a great number of its inhabitants. In November 1864, when a hostile Spanish fleet was on the coast, a congress of South American plenipotentiaries was held here to concert measures of mutual defence. Lima has been the principal sufferer in the many revolts which have convulsed the republic, and many of them originated in the city itself. During the earlier part of this period the capital twice fell into the hands of foreigners, once in 1836 when the Bolivian general Santa Cruz made himself the chief of a Bolivian-Peruvian confederation, and again in 1837 when an invading force of Chileans and Peruvian refugees landed at Ancon and defeated the Peruvian forces under President Orbegoso. The city prospered greatly under the two administrations of President Ramon Castilla, who gave Peru its first taste of peace and good government, and under those of Presidents Balta and Pardo, during which many important public improvements were made. The greatest calamity in the history of Lima was its occupation by a Chilean army under the command of General Baquedano after the bloody defeat of the Peruvians at Miraflores on the 15th of January 1881. Chorillos and Miraflores with their handsome country residences had already been sacked and burned and their helpless residents murdered. Lima escaped this fate, thanks to the intervention of foreign powers, but during the two years and nine months of this occupation the Chileans systematically pillaged the public edifices, turned the old university of San Marcos into barracks, destroyed the public library, and carried away the valuable contents of the Exposition palace, the models and apparatus of the medical school and other educational institutions, and many of the monuments and art treasures with which the city had been enriched. A forced contribution of $1,000,000 a month was imposed upon the population in addition to the revenues of the custom house. When the Chilean garrison, under Captain Lynch, was defeated, and the Peruvians reoccupied the city, 12 months later, in October 1883, it took 300 wagons to carry away the plunder which had not already been shipped. Of the government palace and other public buildings nothing remained but the bare walls. The buoyant character of the people, and the sympathy and assistance generously offered by many civilized nations, contributed to a remarkably speedy recovery from so great a misfortune. Under the direction of its keeper, Don Ricardo Palma, 8315 volumes of the public library were recovered, to which were added valuable contributions from other countries. The portraits of the Spanish viceroys were also recovered, except five, and are now in the portrait gallery of the Exposition palace. The poverty of the country after the war made recovery difficult, but years of peace have assisted it.

LIMAÇON (from the Lat. limax, a slug), a curve invented by Blaise Pascal and further investigated and named by Gilles Personne de Roberval. It is generated by the extremities of a rod which is constrained to move so that its middle point traces out a circle, the rod always passing through a fixed point on the circumference. The polar equation is $r = a + b \cos \theta$, where $a = \text{length of the rod}$, and $b = \text{diameter of the circle}$. The curve may be regarded as an epitrochoid (see EPITROCHOID) in which the rolling and fixed circles have equal radii. It is the inverse of a
central conic for the focus, and the first positive pedal of a circle for any point. The form of the limaçon depends on the ratio of the two constants; if a be greater than b, the curve lies entirely outside the circle; if a equals b, it is known as a cardioid (q.v.); if a is less than b, the curve has a node within the circle; the particular case when b = 2a is known as the tristrich (q.v.). In the figure (1) is a limaçon, (2) the cardioid, (3) the tristrich.

Properties of the limaçon may be deduced from its mechanical construction; thus the length of a focal chord is constant and the normals at the extremities of a focal chord intersect on a fixed circle. The area is $(\theta^2+\alpha^2)/2$, and the length is expressible as an elliptic integral.

**LIMASOL,** a seaport of Cyprus, on Akrotiri Bay of the south coast. Pop. (1901) 8298. Excepting a fort attributed to the close of the 12th century the town is without antiquities of interest, but in the neighbourhood are the ancient sites of Amathus and Curium. Limasol has a considerable trade in wine and carobs. The town was the scene of the marriage of Richard I., king of England, with Berengaria, in 1101.

**LIMB.** (1) In O.Eng. Lim, cognate with the O. Nor. and Icel. limr, Swed. and Dan. lem; probably the word is to be referred to a root lī- seen in an obsolete English word “lath,” a limb, and in the Ger. Glied), originally any portion or member of the body, but now restricted in meaning to the external members of the body of an animal apart from the head and trunk, the legs and arms, or, in a bird, the wings. It is sometimes used of the lower limbs only, and is synonymous with “leg.” The word is also used of the main branches of a tree, of the projecting spurs of a range of mountains, of the arms of a cross, &c. As a translation of the Lat. membrum, and with special reference to its use as the “body of Christ,” “limb” was frequently used by ecclesiastical writers of the 16th and 17th centuries of a person as being a component part of the church; cf. such expressions as “limb of Satan,” “limb of the law,” &c. From the use of membrum in medieval Latin for an estate dependent on another, the name “limb” is given to an outlying portion of another, or to the subordinate members of the Cinque Ports, attached to one of the principal towns; Pevensey was thus a “limb” of Hastings. (2) An edge or border, frequently used in scientific language for the boundary of a surface. It is thus used of the edge of the disk of the sun or moon, of the expanded part of a petal or sepal in botany, &c. This word is a shortened form of “limbo” or “limbus,” Lat. for an edge, for the theological use of which see Limbus.

**LIMBACH,** a town in the kingdom of Saxony, in the manufacturing district of Chemnitz, 5 m. N.W. of that city. Pop. (1903) 13,723. It has a public park and a monument to the composer Pache. Its industries include the making of worsteds, cloth, silk and sewing-machines, and dyeing and bleaching.

**LIMER,** an homonymous word, having three meanings.

(1) A two-wheeled carriage forming a detachable part of the equipment of all guns on travelling carriages and having on it a framework to contain ammunition boxes, and, in most cases, seats for two or three gunners. The French equivalent is autotrain, the Ger. Prot (see Artillery and Ordnance). (2) An adjective meaning pliant or flexible and so used with reference to a person’s mental or bodily qualities, quick, nimble, adroit. (3) A nautical term for the holes cut in the flooring in a ship above the keelson, to allow water to drain to the pumps.

The etymology of these words is obscure. According to the New English Dictionary the origin of (1) is to be found in the Fr. limbar, a derivative of limon, the shaft of a vehicle, a meaning which appears to have been in English from the 15th century but is now obsolete, except apparently among the miners of the north of England. The earlier English forms of the word are lymor or limmer. "Skot suggests that (2) is connected with "limp," which he refers to a Teutonic base lisp, meaning to hang down.

**LIMBORCH,** PHILIPP VAN (1632-1712), Dutch Remonstrant theologian, was born on the 9th of June 1632, at Amsterdam, where his father was a lawyer. He received his education at Utrecht, at Leiden, in his native city, and finally at Utrecht University, which he entered in 1652. In 1657 he became a Remonstrant pastor at Gouda, and in 1667 he was transferred to Amsterdam, where, in the following year, the office of professor of theology in the Remonstrant seminary was added to his pastoral charge. He was a friend of John Locke. He died at Amsterdam on the 30th of April 1712.

His most important work, Institutiones theologiae christianae, ad praxin pietaetis et promotionem pacis christianae unice directae (Amsterdam, 1686, 5th ed., 1735), is a full and clear exposition of the theological system of Gerardus van der Leest and its development. The fourth edition (1715) included a posthumous "Relatio historica de origine et progressu controversiarum in fideliter Belgio de prae-destinatione," Limborch also wrote De veritate religionis Christianae amica collatio cum erudito Judaeo (Gouda, 1667); Historia Inquisitionis (1692), in four books prefixed to the "Liberi Sententiarum Inquisitionis Tolosanes" (1397-1323); and Commentarius in Acta Apostolorum et in Epistolas ad Romanos et ad Hebraeos (Rotterdam, 1708). In 1693 appeared a Dutch translation of all the principal works of his predecessors, and of Epistolae ecclesiasticae praestantium ac eruditorum virorum (Amsterdam, 1684), chiefly by Jakobus Arminius, Joannes Uytenbogardus, Konrad Vorstius (1599-1622), Hugo Grotius, Simon Episcopius (his grand-uncle) and Caspar Barlaeus; they are of great value for the history of Arminianism. An English translation of the Theologia was published in 1702 by William Jones (A Complete System of the Bible of the Body and Soul, 1717); and a translation of the Historia Inquisitionis, by Samuel Chandler, with "a large introduction concerning the rise and progress of persecution and the real and pretended causes of its precipitation," prefixed, appeared in 1731. See HERING, Handbook, Rekenschoolposter.

**LIMBURG,** one of the many small feudal states into which the duchy of Lower Lorraine was split up in the second half of the 11th century. The first Duke Walram of Lower Lorraine was the daughter of Frederick of Luxembourg, Duke of Lower Lorraine (d. 1065), who bestowed upon him a portion of his possessions lying upon both sides of the river Meuse. It received its name from the strong castle built by Count Walram on the river Vesdre, where the town of Limburg now stands. Henry, Walram's son (d. 1110), was turbulent and ambitious. On the death of Godfrey of Bouillon (1089) he forced the emperor Henry IV. to recognize him as Duke of Lower Lorraine. He was afterwards deposed and imprisoned by Count Godfrey of Louvain on whom the ducal title had been bestowed by the emperor Henry V. (1106). For three generations the possession of the ducal title was disputed between the rival houses of Limburg and Louvain. At length a reconciliation took place (1155); the name of duke of Lower Lorraine henceforth disappears, the rulers of the territory on the Meuse become dukes of Limburg, those of the larger territory to the west dukes of Brabant. With the death of Duke Walram IV. (1283), who was the last to succeed to this duchy, his son-in-law who was married to Reinald I., count of Guelders. Irmingard died without issue (1282), and her cousin, Count Adolph of Berg, laid claim to the duchy. His rights were disputed by Reinald, who was in possession and was recognized by the emperor. Too weak to assert his claim by force of arms Adolph sold his rights (1283) to John, duke of Brabant (q.v.). This led to a long and desolating war for five years, at the end of which (1288), finding the power of Brabant superior to his own Reinald in his turn sold his rights to count Henry III. of Luxembourg. Henry and Reinald, supported by the archbishop of Cologne and other allies, now raised a great army. The rival forces met at Woeringen (5th of June 1288) and John of Brabant (q.v.) gained a complete victory. It proved decisive, the duchies of Limburg and Brabant passing under the rule of a common sovereign. The duchy comprised during this period the bailiwicks of Hervé, Montzen, Baelen, Sprimont and Walhain, and the counties of Rolduc, Daelheim and Falkenberg, to which was added in 1350 the town of
Maastricht. The provisions and privileges of the famous Charter of Brabant, the Joyeuse Entrée (q.v.), were from the 15th century extended to Limburg and remained in force until the French Revolution. By the treaty of Westphalia (1648) the duchy was divided into two portions, the counties of Daalhem and Valkenberg with the town of Maastricht being ceded by Spain to the United Provinces, where they formed what was known as a "Generality-Land." At the peace of Rastatt (1774) the southern portion passed under the dominion of the Austrian Habsburgs and formed part of the Austrian Netherlands until the French conquest in 1794. During the period of French rule (1794–1814) Limburg was included in the two French departments of Ourthe and Meuse Inferieure. In 1814 the old name of Limburg was restored to one of the provinces of the newly created kingdom of the Netherlands, but the new Limburg comprised besides the duchy itself, a piece of Gelderland and the county of Looz. At the revolution of 1830 Limburg, with the exception of Maastricht, threw in its lot with the Belgians, and during the nine years that King William refused to recognize the existence of the kingdom of Belgium the Limburgers sent representatives to the legislature at Brussels and were treated as Belgians. When in 1839 the Dutch king suddenly announced his intention of accepting the terms of the settlement proposed by the treaty of London, as drawn up by representatives of the great powers in 1817, Belgium found herself compelled to relinquish portions of Limburg and Luxemburg. The part of Limburg that lay on the right bank of the Meuse, together with the town of Maastricht and a number of communes—Weert, Haelen, Kempen, Horst, &c.—on the left bank of the river, became a sovereign duchy under the rule of the king of Holland. In exchange for the cession of the rights of the Germanic confederation over the portion of Luxemburg, which was annexed by the treaty to Belgium, the duchy of Limburg (excepting the communes of Maastricht and Venloo) was declared to belong to the Germanic confederation. This somewhat unsatisfactory condition of affairs continued until 1866, when at a conference of the great powers, held in London to consider the Luxemburg question (see Luxemburg), it was agreed that Limburg should be freed from every political tie with Germany. Limburg became henceforth an integral part of Dutch territory.

See P. S. Ernest, Histoire du Limbourg (7 vols., Liége, 1837–1852); C. J. Lucx, De Lieden van Overmaas in Zonderland 1662 (Leiden, 1888); and W. L. P. De Lieden van Maastricht en de omgeving (1850); Diplomatique bescheiden betreffende de Limburg-Luxemburgsche aangelegenheden 1866–1867 (The Hague, 1868); and R. Fruin, Geschied. der Staats-Instellingen in Nederland (The Hague, 1865).

LIMBURG, or LIMBOURG, the smallest of the nine provinces of Belgium, occupying the north-east corner of the kingdom. It represents only a portion of the ancient duchy of Limburg (see above). The part east of the Meuse was transferred to Holland by the London conference, and a further portion was attached to the province of Liége including the old capital now called Dolein. Much of the province is represented by the wild heath district called the Campine, recently discovered to form an extensive coal-field. The operations for working it were only begun in 1906. North-west of Hasselt is Beverloo, where all the Belgian troops go through a course of instruction annually. Among the towns are Hasselt, the capital, St Trond and Looz. From the last named is derived the title of the family known as the dukes of Looz, whose antiquity equals that of the extinct reigning family of Limburg itself. The title of duc de Looz is one of the four existing ducal titles in the Netherlands, the other three being d'Areberg, Croy and d'Ursel. Limburg contains 603,085 acres or 942 sq. m. In 1904 the population was 255,550, giving an average of 271 per sq. m.

LIMBURG, a town of Germany, in the Prussian province of Hesse-Nassau, on the Lahn, here crossed by a bridge dating from 1315, and on the main line of railway from Coblenz to Lollar and Cassel, with a branch to Frankfort-on-Main. Pop. (1905) 9017. It is the seat of a Roman Catholic bishop. The small seven-towered cathedral, dedicated to St George the martyr, is picturesquely situated on a rocky overhanging the river. This was founded by Conrad Kurzbold, count of Niederlahnau, early in the 10th century, and was consecrated in 1335. It was restored in 1872–1878. Limburg has a castle, a new town hall and a seminary for the education of priests; its industries include the manufacture of cloth, tobacco, soap, machinery, pottery and leather. Limburg, which was a flourishing place during the middle ages, had its own line of counts until 1414, when it was purchased by the elector of Trier. It passed to Nassau in 1803. In September 1796 it was the scene of a victory gained by the Austrians under the archduke Charles over the French.

See Hillebrand, Limburg an der Lahn unter Pfandherrschaft 1344–1866 (Wiesbaden, 1874).

LIMBURG, the south-easternmost and smallest province of Holland, bounded N. by Gelderland, N.W. by North Brabant, S.W. by the Belgian province of Limburg, and S. by that of Liége, and E. by Germany. Its area is 850 sq. m., and its population in 1900 was 281,034. It is watered by the Meuse (Maas) which forms part of its south-western boundary (with Belgium) and then flows through its northern portion, and by such tributaries as the Geul and Roer (Ruhr). Its capital is Maastricht, which gives name to one of the two administrative districts into which it is divided, the other being Roermond.

LIMBURG CHRONICLE, or FESTI LIMBURGENSIS, the name of a German chronicle written most probably by Tileman Elhen von Wolffhagen after 1402. It is a source for the history of the Rhineland between 1336 and 1398, but is perhaps more valuable for the information about German manners and customs, and the old German folk-songs and stories which it contains. It has also a certain philological interest.

The chronicle was first published by J. F. Faust in 1617, and has been edited by A. Wys for the Monumenta Germaniae historica, Deutsche Chroniken, Band iv. (Hanover, 1883). See A. Wys, Die Limburger Chronik untersucht (Marburg, 1875).

LIMBURGITE, in petrology, a dark-coloured volcanic rock resembling basalt in appearance, but containing normally no felspar. The name is taken from Limburg (Germany), where they occur in the well-known rock of the Kaiserstuhl. They consist essentially of olivine and augite with a brownish glassy ground mass. The augite may be green, but more commonly is brown or violet; the olivine is usually pale green or colourless, but is sometimes yellow (hyalosiderite). In the ground mass a second generation of small eumorphic augites frequently occurs; more rarely olivine is present also as an ingredient of the matrix. The principal accessory minerals are titaniferous iron oxides and apatite. Felspar though sometimes present is never abundant, and the rock is also distinguished by the large phenocysts of dark brown hornblende and biotite are found, mostly with irregular borders blackened by recrystallization; in others there are large crystals of soda orthoclase or anorthoclase. Hayne is an ingredient of some of the limburgites of the Cape Verde Islands. Rocks of this group occur in considerable numbers in Germany (Rhine district) and in Bohemia, also in Scotland, Auvergne, Spain, Africa (Kilimanjarro), Brazil, &c. They are associated principally with basalts, nepheline and leucite basalts and monchiquites. From the last-named rocks the limburgites are not easily separated as the two classes bear a very close resemblance in structure and in mineral composition, though many authorities believe that the ground mass of the monchiquites is not a glass but crystalline analcite. Limburgites may occur as flows, as sills or dykes, and are sometimes highly vesicular. Closely allied to them are the augitites, which are distinguished only by the absence of olivine; examples are known from Bohemia, Auvergne, the Canary Islands, Ireland, &c.

LIMBUS (Lat. for "edge," "ringe," e.g. of a garment), a theological term denoting the border of hell, where dwell those who, while not condemned to torture, yet are deprived of the joy of heaven. The more common form in English is "limbo," which is used both in the technical theological sense and derivatively in the sense of "prison," or for the condition of being lost, deserted, obsolete. In theology there are (1) the Limbus Infantum, and (2) the Limbus Paterum.

1. The Limbus Infantum or Puerorum is the abode to which
human beings dying without actual sin, but with their original sin unwashed away by baptism, were held to be consigned; the category included, not unbaptized infants merely, but also idiots, cretins and the like. The word "limbus," in the theological application, occurs first in the Summa of Thomas Aquinas; for its extensive currency it is perhaps most indebted to the Comedy of Dante (Inf. c. 4). The question as to the destiny of infants dying unbaptized presented itself to theologians at a comparatively early period. Generally speaking it may be said that the Greek fathers inclined to a cheerful and the Latin fathers to a gloomy view. Thus Gregory of Nazianzus (Orat. 40) says "that such children as die unbaptized without their own fault shall neither be glorified nor punished by the righteous Judge, as having done no wickedness, though they die unbaptized, and as rather suffering loss than being the authors of it." Similar opinions were expressed by Gregory of Nyssa, Severus of Antioch and others—opinions which it is almost impossible to distinguish from the Pelagian view that children dying unbaptized might be admitted to eternal life, though not to the kingdom of God. In his recoil from Pelagian heresy, Augustine was compelled to sharpen the antithesis between the state of the saved and that of the lost, and taught that there are only two alternatives—to be with Christ or with the devil, to be with Him or against Him. Following up, as he thought, his master's teaching, Fulgentius declared that it is to be believed as an indubitable truth that, "not only men who have come to the use of reason, but infants dying, whether in their mother's womb or after birth, without baptism in the name of the Father, Son and Holy Ghost, are punished with everlasting punishment in eternal fire." Later theologians and schoolmen followed Augustine in rejecting the notion of any final position intermediate between heaven and hell, but otherwise inclined to take the mildest possible view of the destiny of the irresponsible and unbaptized. Thus the proposition of Innocent III. that "the punishment of original sin is deprivation of the vision of God," is practically repeated by Aquinas, Scotus, and all the other great theologians of the scholastic period, the only outstanding exception being that of Gregory of Rimini, who on this account was afterwards called "tortor infantum." The first authoritative declaration of the Latin Church upon this subject was that made by the second council of Lyons (1274), and confirmed by the council of Florence (1439), with the concurrence of the representatives of the Greek Church, to the effect that "the souls of those who die in mortal sin or in original sin only forthwith descend into hell, but to be punished with unequal punishments." Perrone remarks (Proel. Theol. pt. iii. chap. 6, art. 4) that the damnation of infants and also the comparative lightness of the punishment involved in this are thus de fide; but nothing is determined as to the place which they occupy in hell, as to what constitutes the disparity of their punishment, or as to their condition after the day of judgment. In the council of Trent there was considerable difference of opinion as to what was implied by the deprivation of the vision of God; and so devoted was the Dominicans maintaining the severer view that the "limbus infantum" was a dark subterranean fireless chamber, while the Franciscans placed it in a region of light above the earth. Some theologians continue to maintain with Bellarmine that the infants "in limbo" are affected with some degree of sadness on account of a felt privation; others, following the Nodus praedestinationes of Celestine Sfrondati (1649-1660), hold that they enjoy every kind of natural felicity, as regards their souls now, and as regards their bodies after the resurrection, just as if Adam had not sinned. In the condemnation (1749) of the synod of Pistoia (1786), the twenty-sixth article declares it to be false, rash and injurious to treat as Pelagian the doctrine that those dying in original sin are not punished with fire, as if that meant that there is an intermediate place, free from fault and punishment, between the kingdom of God and everlasting damnation.

2. The Limbus Patrum, Limbus Inferni or Sinus Abrahae ("Abraham's Bosom"), is defined in Roman Catholic theology as the place in the underworld where the saints of the Old Testament were confined until liberated by Christ on his "descent into hell." Regarding the locality and its pleasantness or painfulness nothing has been taught as de fide. It is sometimes regarded as having been closed and empty since Christ's descent, but other authors do not think of it as separate in place from the limbus infantum. The whole idea, in the Latin Church, has been justly described as the mere caput mortuum of the old catholic doctrine of Hades, which was gradually superseded in the West by that of purgatory.

LIME (O. Eng. lim, Lat. limus, mud, from linere, to smear), the name given to a viscous exudation of the holly-tree, used for snaring birds and known as "bird-lime." In chemistry, it is the popular name of calcium oxide, CaO, a substance employed in very early times as a component of mortars and cementing materials. It is prepared by the burning of limestone (a process described by Dioscorides and Pliny) in kilns similar to those described under CEMENT. The value and subsequent treatment of the product depend on the purity of the limestone; a pure stone yields a "fat" lime which readily slakes; an impure stone, especially if magnesium be present, yields an almost unskalable "poor" lime. See CEMENT, CONCRETE and MORTAR, for details.

Pure calcium oxide "quick-lime," obtained by heating the pure carbonate, is a white amorphous substance, which can be readily melted and boiled in the electric furnace, cubic and acicular crystals being deposited on cooling the vapour. It combines with water, evolving much heat and crumbling to pieces; this operation is termed "slaking" and the resulting product "slaked lime"; it is chemically equivalent to the conversion of the oxide into hydrate. A solution of the hydrate in water, known as lime-water, has a weakly alkaline reaction; it is employed in the detection of carbonic acid. "Milk of lime" consists of a cream of the hydrate and water. Dry lime has no action upon chlorine, carbon dioxide and sulphur dioxide, although in the presence of water combination ensues.

In medicine lime-water, applied externally, is an astringent and dessicative, and it enters into the preparation of limen- turum calcis and carron oil which are employed to heal burns, eczema, &c. Applied internally, lime-water is an antacid; it prevents the curdling of milk in large lumps (hence its prescription for infants); it also acts as a gastric sedative. Calcium phosphate is much employed in treating rickets, and calcium chloride in haemoptysis and haemophilia. It is an antidote for mineral and oxalic acid poisoning.

Lime, or Linden. The lime trees, species of Tilia, are familiar timber trees with sweet-scented, honeyed flowers, which are borne on a common peduncle proceeding from the middle of a long bract. The genus, which gives the name to the natural order Tiliaeae, contains about ten species of trees, natives of the north temperate zone. The general name Tilia europaea, the name given by Linnaeus to the European lime, includes several well-marked sub-species, often regarded as distinct species. These are: (1) the small-leaved lime, T. parisifolia (or cordoada), common in woods in England, and wild throughout Europe except in the extreme south-east, and Russian Asia. (2) T. intermedia, the common lime, which is widely planted in Britain but not wild there, has a less northerly distribution than T. cordata, from which it differs in its somewhat larger leaves and downy fruit. (3) The large-leaved lime, T. platyphyllos (or T. grandifolia), occurs only as an introduction in Britain, and is wild in Europe south of Denmark. It differs from the other two limes in its larger leaves, often 4 in. across, which are downy beneath, its downy twigs and its prominently ribbed fruit. The lime sometimes acquires a great size; one is recorded in Norfolk as being 16 yds. in circumference, and Ray mentions one of the same girth. The famous lime tree which gave the town of Neuenstadt in Württemberg the name of Neuenstadt an der grossen Linden was 9 ft. in diameter.

The lime is a very favourite tree. It is an object of beauty in

1 This is an altered form of O. Eng. and M. Eng. lind; cf. Ger. Linden, cognate with Gr. ὅρη, the silver fir. "Linden" in English means properly "made of lime—or lind—wood," and the transference to the tree is due to the Ger. Lindenbaum.
LIMERICK, a western county of Ireland, in the province of Munster, bounded N. by the estuary of the Shannon and the counties of Clare and Tipperary, E. by Tipperary, S. by Cork and W. by Kerry. The area is 686,842 acres, or about 1064 sq. m. The greater part of the county is comparatively level, but in the south-east the picturesque Galtees, which extend into Tipperary, attain in Galtymore a height of 3051 ft., and on the west, stretching into Kerry, there is a circular amphitheatre of less elevated mountains. The Shannon is navigable for large vessels to Limerick, above which are the rapids of Doonans and Castleroy, and a canal. The Shannon is widely famous as a sporting river, and Castlemagner is a well-known centre. The Maigue, which rises in the Galtees and flows into the Shannon, is navigable as far as the town of Adare.

Limerick is mainly a Carboniferous Limestone county, with fairly level land, broken by ridges of Old Red Sandstone. On the northeast, the latter rock rises on Slevielven, round a Silurian core, to 1523 ft. In the south, Old Red Sandstone rises above an enclosed area of Silurian shale, forming the Ballyhoura Hills. The opposite seacoast of Old Red Sandstone forms the Ballyhoura Hills and the Cork border. Volcanic ashes, andesites, and intrusive sheets of basic rock, mark an eruptive episode in the Carboniferous Limestone. These are well seen along Carrigogunnell Castle, and in a ring of hills round Limerick. At Ballybrack, and near a rising land, called Limerick Hill, inmates are employed chiefly in agriculture, but coarse woollens are manufactured, and also paper, and there are many Tiavern and four mills. Formerly there were flour mills, and cotton-mills, but the factory industry is now extinct. Limerick is the headquarters of an important salmon-fishery on the Shannon. The railway communications are entirely included in the Great Southern and Western system, whose main line crosses the south-eastern corner of the county, with two branches to the city of Limerick from Limerick Junction and from Charleville, and lines from Limerick south-westward to Tralee in county Kerry, and to Foyles on the Shannon estuary. Limerick is also served by a line from the north through county Tipperary. The port of Limerick, at the head of the estuary, is the most important on the west coast.

Limerick village appears to have been originally a fishing settlement. At an early date Limerick was a military centre, and a place of refuge for the nobility when driven from their castles by the Danes. The town was, as a result, till the 19th century, a place of importance, and the market town of the county.

Limerick is a county of Ireland, with an area of 686,842 acres. It is located in the province of Munster and is bordered by counties Clare and Tipperary to the north, Cork and Kerry to the west, and by the Shannon River to the east. The county is characterized by a mix of lowlands and mountains, with the Shannon River and its tributaries forming a significant part of the landscape. Limerick is the largest urban area in the county and serves as the county town.

The economy of Limerick is based on agriculture, with a significant presence of farming and livestock production. The county is also home to a number of industries, including manufacturing and services. The Shannon Estuary is a valuable resource for fishing and tourism, with the city of Limerick serving as a hub for these activities.

Limerick is rich in history and culture, with numerous historical sites and cultural landmarks. The Shannon River is a significant waterway, providing opportunities for recreation and transportation. The county is also known for its natural beauty, with mountains and forests offering opportunities for outdoor activities such as hiking and cycling.

In recent years, Limerick has undergone significant development, with the creation of new urban areas and infrastructure projects. The city is home to a number of major employers and has a strong educational base, including the University of Limerick and other higher education institutions.

Overall, Limerick is a dynamic and diverse county, offering a range of cultural, historical, and natural experiences for both residents and visitors.
can moor alongside at spring tides. The principal imports are grain, sugar, timber and coal. The exports consist mainly of agricultural produce. The principal industrial establishments include flour-mills (Limerick supplying most of the west of Ireland with flour), factories for bacon-curing and for condensed milk and creameries. Some brewing, distilling and tanning are carried on, and the manufacture of very beautiful lace is maintained at the Convent of the Good Shepherd; but a formerly important textile industry has lapsed. The salmon fisheries of the Shannon, for which Limerick is the headquarters of a district, are the most valuable in Ireland. The city is governed by a corporation, and the parliamentary borough returns one member.

Limerick is said to have been the Regia of Ptolemy and the Rosse-de-Nailléagh of the Annals of Multifran. There is a tradition that it was visited by St Patrick in the 5th century, but it is first authentically known as a settlement of the Danes, who sacked it in 812 and afterwards made it the principal town of their kingdom of Limerick, but were expelled from it towards the close of the 10th century by Brian Boromyne. From 1106 till its conquest by the English in 1174 it was the seat of the kings of Thomond or North Munster, and, although in 1178 the kingdom of Limerick was given by Henry II. to Herbert Fitz-herbert, the city was frequently in the possession of the Irish chieftains till 1195. Richard I. granted it a charter in 1197. By King John it was committed to the care of William de Burgo, who founded English Town, and for its defence erected a strong castle. The city was frequently besieged in the 13th and 14th centuries. In the 15th century its fortifications were extended to include Irish Town, and until their demolition in 1760 it was one of the strongest fortresses of the kingdom. In 1631 it was taken by General Ireton, and after an unsuccessful siege by William III. in 1696 its resistance was terminated on the 3rd of October of the following year by the treaty of Limerick. The dismantling of its fortifications in 1769, but fragments of the old walls remain. The original municipal rights of the city had been confirmed and extended by a succession of sovereigns, and in 1609 it received a charter constituting it a county of a city, and also incorporating a society of merchants of the staple, with the same privileges as the merchants of the staple of Dublin and Waterford. The powers of the corporation were remodelled by the Limerick Regulation Act of 1823. The prosperity of the city dates chiefly from the foundation of Newtown Pery in 1769 by Edmund Sexton Pery (d. 1806), speaker of the Irish House of Commons, whose family subsequently received the title of the earldom of Limerick. Under the Local Government Act of 1858 Limerick became one of the six county boroughs having a separate county council.

LIMERICK, a name which has been adopted to distinguish a certain form of verse which began to be cultivated in the middle of the 19th century. A limerick is a kind of burlesque couplet written in five lines. In its earlier form it had two rhymes, the word which closed the first or second line being usually employed at the end of the fifth, but in later varieties different rhyming words are employed. There is much uncertainty as to the meaning of the name, and as to the time when it became attached to a particular species of nonsense verses. According to the New Eng. Dict. "a song has existed in Ireland for a very considerable time, the construction of the verse of which is identical with that of Lear's" (see below), and in which the invitation is repeated, "Will you come up to Limerick?" Unfortunately, the specimen quoted in the New Eng. Dict. is not only not identical with, but does not resemble Lear's. Whatever be the derivation of the name, however, it is now universally used to describe a set of verses formed on this model, with the variations in rhyme noted above:—

``There was an old man who said, 'Hush! I perceive a young bird in that bush!'
When they said, 'Is it small?'
He replied, 'Not at all!
It is five times the size of the bush.'"

The invention, or at least the earliest general use of this form, is attributed to Edward Lear, who, when a tutor in the family of the earl of Derby at Knowsley, composed, about 1834, a large number of nonsense-limericks to amuse the little grandchildren of the house. Many of these he published, with illustrations, in 1846, and they are enjoyed and still enjoy an extreme popularity. Lear preferred to give a geographical colour to his absurdities, as in:—
``There was an old person of Tartary
Who cut through his jugular artery,
When up came his wife,
And exclaimed, 'O my Life,
How your loss will be felt through all Tartary!'"

but this is by no means essential. The neatness of the form has led to a very extensive use of the limerick for all sorts of mock-serious purposes, political, social and sarcastic, and a good many specimens have achieved a popularity which has been all the wider because they have, perforce, been confined to verbal transmission. In recent years competitions on the missing word type have had considerable vogue, the competitor, for instance, having to supply the last line of the limerick.

LIMES GERMANICUS. The Latin noun limes denoted generally a path, sometimes a boundary path (possibly its original sense) or boundary, and hence it was utilized by Latin writers occasionally to denote frontiers definitely delimited and marked in some distinct fashion. This latter sense has been adapted and extended by modern historians concerned with the frontiers of the Roman Empire. Thus the Wall of Hadrian in north England (see BRITAIN: Roman) is now sometimes styled the Limes Britannicus, the frontier of the Roman province of Arabia facing the desert the Limes Arabicus and so forth. In particular the remarkable frontier lines which bounded the Roman provinces of Upper (Southern) Germany and Raetia, and which at their greatest development stretched from near Bonn on the Rhine to near Regensburg on the Danube, are often called the Limes Germanicus. The history of these lines is the subject of the following paragraphs. They have in the last fifteen years become much better known through systematic excavations financed by the German empire and through other researches connected therewith, and though many important details are still doubtful, their general development can be traced.

From the death of Augustus (a.d. 14) till after a.d. 70 Rome accepted as her German frontier the water-boundary of the Rhine and upper Danube. Beyond these rivers she held only the fertile plain of Frankfort, opposite the Roman border fortress of Moguntiacum (Mainz), the southernmost slopes of the Black Forest and a few scattered têtes-du-pont. The northern section of this frontier, where the Rhine is deep and broad, remained the Roman boundary till the empire fell. The southern part was different. The upper Rhine and upper Danube are easily crossed. The frontier which they form is inconveniently long, enclosing an acute-angled wedge of foreign territory—the modern Baden and Württemberg. The German populations of these lands seem in Roman times to have been scanty, and Roman subjects from the modern Alsace and Lorraine had drifted across the river eastwards. The motives alike of geographical convenience and of the advantages to be gained by recognizing these movements of Roman subjects combined to urge a forward policy at Rome, and when the vigorous Vespasian had succeeded the fool-criminal Nero, a series of advances began which gradually closed up the acute angle, or at least rendered it obtuse.

The first advance came about 74, when what is now Baden was invaded and in part annexed and a road carried from the Roman base on the upper Rhine, Strassburg, to the Danube just above Ulm. The point of the angle was broken off. The second advance was made by Domitian about a.d. 85. He pushed out from Moguntiacum, extended the Roman territory east of it and enclosed the whole within a systematically delimited and defended frontier with numerous blockhouses along it and larger forts in the rear. Among the blockhouses was one which by various enlargements and refoundations grew into the well-known Saulburg fort on the Taunus near Homburg. This
LIMESTONE

LIMESTONE, in petrography, a rock consisting essentially of carbonate of lime. The group includes many varieties, some of which are very distinct; but the whole group has certain properties in common, arising from the chemical composition and mineral character of its members. All limestones dissolve readily in cold dilute acids, giving off bubbles of carbonic acid. Citric or acetic acid will effect this change, though the mineral acids are more commonly employed. Limestones, when pure, are soft rocks, readily scratched with a knife-blade or the edge of a coin, their hardness being 3; but unless they are earthy or incoherent, like chalk or silt, they do not disintegrate by pressure with the fingers and cannot be scratched with the fingernail. When free from impurities limestones are white, but they generally contain small quantities of other minerals than calcite which affect their colour. Many limestones are yellowish or creamy, especially those which contain a little iron oxide, iron carbonate or clay. Others are bluish from the presence of iron sulphide, or pyrites or marcasite; or grey and black from admixture with carbonaceous or bituminous substances. Red limestones usually contain haematite; in green limestones there may be glauconite or chlorite. In crystalline limestones or marbles many silicates may occur producing varied colours, e.g. epidote, chlorite, augite (green); vesuvianite and garnet (brown and red); graphite, spinels (black and grey); epidote, chondrodite (yellow). The specific gravity of limestones ranges from 2.4 to 2.6 in typical examples.

When seen in the field, limestones are often recognizable by their method of weathering. If very pure, they may have smooth rounded surfaces, or may be covered with narrow runnels cut out by the rain. In such cases there is very little soil, and plants are found growing only in fissures or crevices where the insoluble impurities of the limestone have been deposited by the rain. The less pure rocks have often eroded or pitted surfaces, showing bands or patches rendered more resistant to the action of the weather by the presence of insoluble materials such as sand, clay or chert. These surfaces are often known from the crust of hydrous oxides of iron produced by the action of the atmosphere on any ferrous ingredients of the rock; they are sometimes black when the limestone is carbonaceous; a thin layer of gritty sand grains may be left on the surface of limestones which are slightly arenaceous. Most limestones which contain fossils show these most clearly on weathered surfaces, and the appearance of fragments of corals, crinoids and shells on the exposed parts of a rock indicate a strong probability that that rock is a limestone. The interior usually shows the organic structures very imperfectly or not at all.

Another characteristic of pure limestones, where they occur in large masses occupying considerable areas, is the frequency with which they produce large, tabular parts at high elevations, or yield only a thin scantly soil covered with short grass. In mountainous districts limestones are often recognizable by these peculiarities. The chalk down are celebrated for the close green sward which they furnish. More impure limestones, like those of the Lias and Oolites, contain enough insoluble mineral matter to yield soils of great thickness and value, e.g. the Cornbrash. In limestone regions all waters tend to be hard, on account of the abundant carbonate of lime dissolved by percolating waters, and caves, swallow holes, sinks, pot-holes and underground rivers may occur in abundance. Some elevated tracts of limestone are very barren (e.g. the Causses), because the rain which falls in them sinks at once into the earth and passes underground. To a large extent this is true of the chalk downs, where surface waters are notably scarce, though at considerable depths the rocks hold large supplies of water.

The great majority of limestones are of organic formation, consisting of the debris of the skeletons of animals. Some are foraminiferal, others are crinoidal, and according to the nature of the creatures whose remains they contain. Of foraminiferal limestones chalk is probably the best known; it is fine, white and rather soft, and is very largely made up of the shells of foraminifera; other foraminifera (see CHALK). Almost equally important are the nummulitic limestones so well developed in Mediterranean countries (Spain, France, the Alps, Greece, Algeria, Egypt, Asia Minor, etc.). The pyramids of Egypt are built mainly of nummulitic limestone. Lime marls and foraminiferal marls with many chambers arranged in spiral order. In Britain the small globular shells of Saccammina are important constituents of some Carboniferous limestones; but the upper portion of that formation in Russia and Asia Minor is distinguished by the occurrence of limestones filled with the spindle-shaped shells of Fusulinia, a genus of foraminifera now extinct.

Coral limestones are being formed at the present day over a large extent of the tropical seas; many existing coral reefs must be of great thickness. The same process has been going on actively since a very early period of the earth's history, for similar rocks are found in great abundance in many geological formations. Some of these limestones are rich in corals; in Devonshire there are deposits which have been described as coral reefs (Devonshire, Germany). The Carboniferous limestone, or mountain limestones of England and North America, is sometimes nearly entirely coralline, and is called coraliferous limestone. The Great Alp and their satellites are so named because they are believed to be merely altered coral reefs. A special feature of coral limestones is that, although they may be to a considerable extent dolomitized, they are generally very free from silt and mechanical impurities.

Crinoidal limestones, though abundant among the older rocks, are not in course of formation on any great scale at the present time, as crinoids, formerly abundant, are now rare. Many Carboniferous and Silurian limestones consist mainly of the little cylindrical joints of these animals. They are easily recognized by their shape, and by the fact that many of them show a tube along their axes, which is often filled up by carbonate of lime; under the microscope these joints often form a perfect network, and are sometimes filled in as a simple crystallite plate with uniform optical properties in polarized light. Remains of other echinoderms (starfishes and sea urchins) are often found in plenty in Secondary and Tertiary limestones, and may be more or less common in the greater part of the rock. Shelly limestones may consist of mollusca or of brachiopoda, the former being common in limestones of all ages while the latter attended their principal development in the Palaeozoic epoch. The shells are often broken and may be preserved before the rock consolidated. Many rocks of this class are impure and

LIMESTONE

into marls and shelly sandstones which were deposited in shallow waters, where land-derived sediment mingled with remains of the creatures which inhabited the water. Fresh-water limestones are mostly of this class and contain shells of those varieties of mollusca which have been, or are, or are assumed to have been, or are the remains of marine animals which are not always converted into limestone in the place where they were formed. In shallow waters, such as are the favourite haunts of mollusca, corals, etc., the tides and storms are frequently sufficiently powerful to shift the loose material on the sea bottom. A large part of a coral reef consists of broken coral rock dislodged from the growing mass and carried upwards to the beach or into the lagoon. Large fragments also fall over the steep outward slope, enclosing well-preserved marine animals. Coral, calcite, and coral sand produced by the waves acting in these detached blocks, are believed to cover two and a half millions of square miles of the ocean floor. Owing to the fragility of the nature of the foraminifera, they readily become disintegrated, especially on the surface, and large fragments often remain in the sea as they sink to the bottom. The chalk in very great part consists of entire shells of foraminifera, and mollusca (such as Inoceramidae, etc.). The Globigerina or the molusca of the modern sea lie on the sea bottom; it occupies nearly fifty millions of square miles of the sea bottom, at an average depth of two thousand fathoms. Pteropod ooze, consisting mainly of the shells of pteropods (mollusca) also has a wide distribution, especially in northern latitudes.

Consolidation may take a considerable extent by pressure, but more commonly cementation and crystallization play a large part in the process. Recent shell sand on beaches and in dunes is often converted into a compact rock by rain water filtering downward, dissolving and redepositing carbonate of lime between the sand grains. In coral reefs also, the mass soon has its cavities more or less obliterated by a deposit of calcite which fills the holes, leaving the whole surface of the rock as a large surface to the solvents, and is more readily attacked than the larger and more compact shell fragments. In fresh-water marls, considerable masses of crystalline calcite may be produced in this way, enclosing well-preserved marine animals. Coral, calcite, and fragments consist of aragonite, whole or principally, and this mineral tends to be replaced by calcite. The aragonite, as seen under the microscope, is usually fibrous or prismatic, the calcite more or less in the form of grains or of prisms, with a well-defined cleavage. The replacement of aragonite by calcite goes on even in shells lying on modern sea shores, and is often very complete in rocks belonging to the older geological periods. By the recrystallization of calcite which fills the cavities, the interior of the shells, corals, foraminifera, etc., becomes occupied by crystalline calcite, sometimes in comparatively large grains, while the original organic structures may be very well-preserved.

Some limestones are exceedingly pure, e.g. the chalk and some varieties of mountain limestone, and these are especially suited for making lime. The majority, however, contain admixture of other substances, of which the commonest are clay and sand. Argillaceous limestones frequently occur in thin or thick beds alternating with shales, as in the Lias of England (the marl series). Friable argillaceous fresh-water limestones are called "marls," and are distinguished from the true marls by the fact that they are the interior of the shells, corals, foraminifera, etc., becomes occupied by crystalline calcite, sometimes in comparatively large grains, while the original organic structures may be very well-preserved.

LIMINA APOSTOLORUM—LIMITATION, STATUTES OF

A period absolutely fixed became in time useless for the purposes of limitation, and the method of counting back a certain number of years from the date of the writs was adopted in the Statute 32 Henry VIII. c. 2, which fixed periods of thirty, fifty and sixty years for various classes of actions named therein. A large number of statutes since that time have established periods of limitation for different kinds of actions. Of those now in force the most important are the Limitation Act 1625 for personal actions in general, and the Real Property Limitation Act 1833 relating to actions for the recovery of land. The latter statute has been repealed and virtually re-enacted by the Real Property Limitation Act 1874, which reduced the period of limitation from twenty years to twelve, for all actions brought after the 1st January 1879. The principal section of the act of 1833 will show the modus operandi: “After the 31st December 1833, no person shall make an entry or distress, or bring an action to recover any land or rent but within twenty years next after the time at which the right to make such entry or distress or to bring such action shall have first accrued to some person through whom he claims, or shall have first accrued to the person making or bringing the same.” Another section defines the times at which the right of action or entry shall be deemed to have accrued in particular cases; e.g. when the estate claimed shall have been an estate or interest in reversion, such right shall be deemed to have first accrued at the time at which such estate or interest became an estate or interest in possession. Thus suppose lands to be let by A to B from 1830 for a period of fifty years, and that a portion of such lands is occupied by C from 1831 without any colour of title from B or A—C’s long possession would be of no avail against an action brought by A for the recovery of the land after the determination of B’s lease. A would have twelve years after the determination of the lease within which to bring his action, and might thus, by an action brought in 1841, disestablish a person who had been in quiet possession since 1831. What the law looks to is not the length of time during which C has enjoyed the property, but the length of time of which A has suffered to elapse since he might first have brought his action. It is to be observed, however, that the Real Property Limitation Act does more than bar the remedy. It extinguishes the right, differing in this respect from the other Limitation Acts, which, while bar the remedy, preserve the right, so that it may possibly become available in some other way than by action.

By section 14 of the act of 1833, when any acknowledgment of the title of the person entitled shall have been given to him or his agent in writing signed by the person in possession, or in receipt of the rents or profits, or the time of the right of the person (to whom such acknowledgment shall have been given) to make an entry or distress or bring an action shall be deemed to have first accrued at the time at which such acknowledgment, or the last of such acknowledgments, was given. By section 15, persons under the disabilities of infancy, lunacy or coverture, or beyond seas, and their representatives, are to be allowed ten years from the termination of this disability, or death (which shall have first happened), notwithstanding that the ordinary period of limitation shall have expired.

By the act of 1625 actions of trespass, detinue, trover, replevin or account, actions on the case (except for slander), actions of debt arising out of a simple contract and actions for arrears of rent not due upon specialty shall be limited to six years from the date of the cause of action. Actions for assault, menace, battery, wounds and imprisonment are limited to four years, and actions for slander to two years. Persons labouring under the disabilities of infancy, lunacy or unsoundness of mind are allowed the same time after the removal of the disability. When the defendant was "beyond seas" (i.e. outside the United Kingdom and the adjacent islands) an extension of time was allowed, but by the Real Property Limitation Act of 1874 such an allowance is excluded as to real property, and as to other matters by the Mercantile Law Amendment Act 1856.

An acknowledgment, whether by payment on account or by mere spoken words, was formerly sufficient to take the case out
of the statute. The Act 9 Geo. IV. c. 14 (Lord Tenterden’s act) requires any promise or admission of liability to be in writing and signed by the party to be charged, otherwise it will not bar the statute.

Contracts under seal are governed as to limitation by the act of 1883, which provides that actions for rent upon any indenture of demise, or of covenant, or debt or any bond or other specialty, and on recognizances, must be brought within twenty years after cause of action. Actions of debt on an award (the submission being not under seal), or for a copyhold fine, or for money levied on a writ of fieri facias, must be brought within six years. With regard to the rights of the crown, the principle obtains that *nullum tempus occurrit regi*, so that no statute of limitation affects the crown without express mention. But by the Crown Suits Act 1769, as amended by the Crown Suits Act 1861, in suits relating to land, the claims of the crown to recover are barred after the lapse of sixty years. For the prosecution of criminal offences generally there is no period of limitation, except where they are punishable on summary conviction. In such case the period is six months by the Summary Jurisdiction Act 1845. But there are various miscellaneous limitations fixed by various statutes of which the following may be noticed. Suits and indictments under penal statutes are limited to two years if the forfeiture is to the crown, to one year if the forfeiture is to the common informer. Penal actions by persons aggrieved are limited to two years by the act of 1833. Prosecutions under the Riot Act can only be sued upon within twelve months after the offence has been committed, and offences against the Customs Acts within three years. By the Public Authorities Protection Act 1893, a prosecution against any person acting in execution of statutory or other public duty must be commenced within six months. Prosecutions under the Criminal Law Amendment Act, as amended by the Prevention of Cruelty to Children Act 1904, must be commenced within six months after the commission of the offence.

Trustees are expressly empowered to plead statutes of limitation by the Trustees Act 1888; indeed, a defence under the statutes of limitations must in general be specially pleaded. Limitation is regarded strictly as a law of procedure. The English courts will therefore apply their own rules to all actions, although the cause of action may have arisen in a country in which different rules of limitation exist. This is also a recognized principle of private international law (see J. A. Foote, *Private International Law*, 3rd ed., 1904, p. 516 seq.).

**United States.**—The principle of the statute of limitations has passed with some modification into the statute-books of every state in the Union except Louisiana, whose laws of limitation are essentially the prescriptions of the civil law drawn from the *Partidas*, or “Spanish Code.” As to personal actions, it is generally provided that they shall be brought within a certain specified time—usually six years or less—from the time when the cause of action accrues, and not after, while for land the “general if not universal limitation of the right to bring action or to make entry is to twenty years after the right to enter or to bring the action accrues” (Bouvier’s *Law Dictionary*, art. “Limitations”).

The constitutional provision prohibiting states from passing laws impairing the obligation of contracts is not infringed by a law of limitations, unless it bars a right of action already accrued without giving a reasonable term within which to bring the action. See Darby and Bosanquet, *Statutes of Limitations* (1890); Hewitt, *Statutes of Limitations* (1893).

**LIMOGES.** A town of west-central France, capital of the department of Haute-Vienne, formerly capital of the old province of Limousin, 176 m. s. by W. of Orleans on the railway to Toulouse. Pop. (1906) town, 75,906; commune, 88,597. The station is a junction for Poitiers, Angoulême, Périgueux and Clermont-Ferrand. The town occupies a hill on the right bank of the Vienne, and comprises two parts originally distinct, the Cité with narrow streets and old houses occupying the lower slope, and the town proper the summit. In the latter a street known as the Rue de la Boucherie is occupied by a powerful and ancient corporation of butchers. The site of the fortifications which formerly surrounded both quarters is occupied by boulevards, outside which are suburbs with wide streets and spacious squares. The cathedral, the most remarkable building in the Limousin, was begun in 1273. In 1313 the choir was completed, and before the middle of the 16th century the transept, with its fine north portal and the first two bays of the nave; from 1875 to 1890 the construction of the nave was continued, and it was united with the west tower (203 ft. high), the base of which belongs to a previous Romanesque church. In the interior there are a magnificent rood loft of the Renaissance, and the tombs of Jean de Langecq (d. 1541) and other bishops. Of the other churches of Limoges, St Michel des Lions (14th and 15th centuries) and St Pierre du Queyroix (12th and 13th centuries) both contain interesting stained glass. The principal modern buildings are the town hall and the law-courts. The Vienne is crossed by a railway viaduct and four bridges, two of which, the Pont St Etienne and the Pont St Martial, date from the 13th century. Among the chief squares are the Place d’Orsay on the site of a Roman amphitheatre, the Place Jourdan with the statue of Marshal J. B. Jourdan, born at Limoges, and the Place d’Aine with the statue of J. L. Gay-Lussac. President Carnot and Denis Dussoub, both of whom have statues, were also natives of the town. The museum has a rich ceramic collection, collections of art, and various national and municipal archives.

Limoges is the headquarters of the XII. army corps and the seat of a bishop, a prefect, a court of appeal and a court of assizes, and has tribunals of first instance and of commerce, a board of trade arbitration, a chamber of commerce and a branch of the Bank of France. The educational institutions include a *lycée* for boys, a preparatory school of medicine and pharmacy, a higher theological seminary, a training college, a national school of decorative art and a commercial and industrial school. The manufacture and decoration of porcelain give employment to about 15,000 persons in the town and its vicinity. Shoe-making and the manufacture of clogs occupy over 2000. Other industries are liqueur-distilling, the spinning of wool and cloth-weaving, printing and the manufacture of paper from straw. Enamelling, which flourished at Limoges in the middle ages and during the Renaissance (see ENAMEL), but subsequently died out, was revived at the end of the 19th century. There is an extensive trade in wine and spirits, cattle, cereals and wood. The Vienne is navigable for rafts above Limoges, and the logs brought down by the current are stopped at the entrance of the town by the large weirs of the Naveix quarter, who form a special gild for this purpose.

Limoges was a place of importance at the time of the Roman conquest, and sent a large force to the defence of Alesia. In 11 B.C. it took the name of Augustus (*Augustorium*); but in the 4th century it was anew called by the name of the *Lemovices*, whose capital it was. It then contained palaces and baths, had its own senate and the right of coinage. Christianity was introduced by St Martial. In the 5th century Limoges was devastated by the Vandals and the Visigoths, and afterwards suffered in the wars between the Franks and Aquitanians and in the invasions of the Normans. Under the Merovingian kings Limoges was celebrated for its mints and its goldsmiths’ work. In the middle ages the town was divided into two distinct parts, each surrounded by walls, forming separate cities with a separate system of administration, an arrangement which survived till 1792. Of these the more important, known as the *Château*, which grew up round the tomb of St Martial in the 9th century, and was surrounded with walls in the 10th and again in the 12th, within the jurisdiction of the bishops, divided the castle and the monastery of St Martial; the other, the *Cité*, which was under the jurisdiction of the bishop—had but a sparse population, the habitable ground being practically covered by the cathedral, the episcopal palace and other churches and religious buildings. In the Hundred Years’ War the bishops sided with the French, while the viscounts were unwilling vassals of the English. In 1370 the *Cité*, which had opened its gates to the French, was taken by the Black Prince and given over to fire and sword.
LIMON—LIMOUSIN, L.

The religious wars, pestilence and famine desolated Limoges in turn, and the plague of 1630–1631 carried off more than 20,000 persons. The wise administrations of Henri d’Aguessel, father of the chancellor, and of Turgot enabled Limoges to recover its former prosperity. There have been several great fires, destroying whole quarters of the city, built, as it were, of wood. That of 1790 lasted for two months, and destroyed 192 houses; and that of 1864 laid under ashes a large area.

Limoges celebrates every seven years a curious religious festival (Fête d’Ostension), during which the relics of St Martial are exposed for seven weeks, attracting large numbers of visitors. It dates from the 16th century, and commemorates the destruction of the old Limoges, and the beginning of the new, which was begun in the same year. The swamps behind the town, and the shallow coral lagoon in front of it, have been filled in. The harbour is protected by a sea-wall built along the low-water line, and an iron pier affords accommodation for large vessels. A breakwater from the harbour to the island of Uivata, about 1200 yds. E. would render Limon a first-class port. There is an excellent water-supply from the hills above the harbour. Almost the entire coffee and banana crops of Costa Rica are sent by rail for shipment at Limon to Europe and the United States. The district (comarca) of Limon comprises the whole Atlantic littoral, thus including the Talamanca country inhabited by uncivilized Indians; the richest banana-growing territories in the country; and the valuable forests of the San Juan Valley. It is much visited by Indians from the nearby jungles of Nicaragua, who come in canoes to fish for turtle. Its chief towns, after Limon, are Reventazon and Matina, both with fewer than 3000 inhabitants.

LIMONITE, or BROWN IRON ORE, a natural ferric hydrate named from the Gr. λαμίων (meadow), in allusion to its occurrence as "boğ-ore" in meadows and marshes. It is never crystallized, but may have a fibrous or microcrystalline structure, and commonly occurs in concretionary forms or in compact and earthy masses; sometimes mammillated, botryoidal, reniform or stalactitic. The colour presents various shades of brown and yellow, and the streak is always brownish, a character which distinguishes it from haematite with a red, or from magnetite with a black streak. It is sometimes called brown haematite.

Limonite is iron ore forming typically with the formula FeO(OH), or 2FeO·3H2O. Its hardness is rather above 5, and its specific gravity varies from 3.5 to 4. In many cases it has been formed from other iron oxides, like haematite and magnetite, or by the alteration of pyrites or chalcopyrite.

By the operation of meteoric agencies, iron pyrites readily pass into limonite, often with retention of external form; and the masses of "gozam" or "gosan" on the outcrop of certain mineral-veins consist of rusty iron ore formed in this way, and associated with cellular quartz. Many deposits of limonite have been found, on being worked, to pass downwards into ferruginous carbonate; and crystals of chalcopyrite converted superficially into limonite are well known. Many specimens of lapis lazuli, like galena, which contain ferrous sulphate, may in like manner yield limonite, on weathering. The ferric hydrate is also readily deposited from ferruginous waters, often by means of organic agencies. Deposits of brown iron ore of great economic value occur in many sedimentary rocks, such as the Lias, Oolites and Lower Greensand of various parts of England. They appear in some cases to be altered limestones and in others altered gauconitic sandstones. An oolithic structure is sometimes found in the case of the calcareous variety, indicating perhaps 30% of iron. The brown-bone ores of Lorraine and Luxemburg are known as "minette," a diminutive of the French mine (ore), in allusion to their low content of metal. Granular and nodular limonite is limonite" or limonite "ore," the former occurring in certain lakes in Sweden, forming the curious "lake ore." Larger concretions formed under other conditions are known as "bean ore." Limonite often forms a cementing medium in ferruginous sands and clays, often of a yellowish-brown colour, and in like manner it is the aglutinating agent in many conglomerates, like the South African "banket," where it is auriferous. In iron-shot sands the limonite may form hollow concretions, known in some cases as "boxes." The "eggs" of certain older vessels are often composed of limonite, containing some substance, like sand, which rattle when the hollow nodule was shaken. Bog iron ore is an impure limonite, usually formed by the influence of micro-organisms, and containing silica, phosphoric acid and organic matter, sometimes with manganese. The various kinds of brown and yellow ochre are mixtures of limonite with clay and other impurities; whilst in iron much manganese oxide is present. Argillaceous brown iron ore is often known in Germany as Thonenstein; but the corresponding term in English (clay iron stone) is applied to nodular forms of impure chalybite.

J. C. Ullmann's name of stilmposiderite, from the Greek στιλπος (shining) is sometimes applied to such kinds of limonite as have a metallic lustre. Another impure limonite is known as thonite, consisting of a partly altered condition of an old iron deposit, often with a brownish tint. The limonite is characterized by its superficial sheen, and is often of a yellowish colour. The formula of stilmposiderite, and hence new species have been recognized. Thus the yellowish brown ore called by E. Schmidt xanthosiderite, from λαμίων (yellow) and ωδινω (iron), contains FeO(OH), or FeO·2H2O; whilst the limoniteenglish "boxes" have the formula Fe(OH)3, or Fe2O3·H2O. On the other hand there are certain forms of ferric hydrate containing less water than limonite, and approaching to haematite in their red colour and streak; such is the mineral which was called hydroxyhaematite by A. Breithaupt, and is now generally known under R. Herrman's name of turgite, from the mines of Turgis, near Bogoslovak in the Ural Mountains. In these forms the formula FeO·H2O probably represents the partial dehydration of limonite, and for further loss of water may pass into haematite or red iron ore. When limonite is dehydrated and oxidized in the presence of carbonic acid, it may give rise to chalybite.

LIMOUSIN (or LIMOSIN), LÉONARD (c. 1505–c. 1577), French painter, the most famous of a family of seven Limosin enamel painters, was the son of a Limosin inkeeper. He is supposed to have studied under Nardon Pénicaud. He was certainly at the beginning of his career influenced by the German school—Pratzer, the Master of the "Virgin of the Greenberg," and the Master of the "Concert at Leipzig." The "Passion of the Lord," after Albrecht Dürer, but this influence was counterbalanced by that of the Italian masters of the school of Fontainebleau, Primaticcio, Rosso, Giulio Romano and Solario, from whom he acquired his taste for arabesque ornament and for mythological subjects. Nevertheless the French tradition was sufficiently ingrained in him to save him from becoming an imitator and from losing his personal style. In 1530 he entered the service of Francis I. as painter and valet de chambre, a position which he retained under Henry II. For both these monarchs he executed many portraits in enamel—among them quite a number of plaques depicting Diane de Poitiers in various characters, plates, vases, ewers, and cups, besides decorative works for the royal palaces, for though he is best known as an enameller distinguished for his colour, and for graceful designs in grisaille on black or bright blue backgrounds, he also enjoyed a great reputation as an oil-painter. His last signed works date the bear title 1574, but the date of his death is uncertain, though it could not have been later than the beginning of 1577. It is on record that he executed close upon two thousand enamels. He is best represented at the Louvre, which owns his two famous votive tablets for the Sainte Chapelle, each consisting of twenty-three plaques, signed L. L. and dated 1553; "La Chasse," depicting Henry II. on a white horse, Diane de Poitiers behind him on horseback; and many portraits, including the kings by whom he was employed, Marguerite de Valois, the duc de Guise, and the cardinal de Lorraine. Other representative examples are...
at the Cluny and Limoges museums. In England some magnificent examples of his work are to be found at the Victoria and Albert Museum, the British Museum, and the Wallace Collection. In the collection of Signor Rocchi, in Rome, is an exceptionally interesting plaque representing Frances I consulting a fortune-teller.

See Léonard Limousin: peintre de portraits (L'Œuvre des peintres émailleurs), by L. Boudery and E. Lchaunaud (Paris, 1897)—a careful study, with an elaborate catalogue of the known existing examples of his art's work. The book deals almost exclusively with the portraits illustrated. See also Alataume and Duplessis, Les Dous Apeules—émaux de Léonard Limousin, &c. (Paris, 1865); L. Boudery, Exposition retrospective de Limousin en 1880 (Limoges, 1886); L., Boudery, Limousin and son œuvre (L'impos, 1885); Limousin et le Limousin (Limoges, 1885); A. Meyer, L'Art de l'émail de Limoges, ancien et moderne (Paris, 1886); Émile Moliner, L'Émailière (Paris, 1891).

LIMOUSIN (Lat. Pagus Lemovicinu, aeg Lemovicinu, regio Lemovicinum, Lemosinum, Limosinum, &c.), a former province of France. In the time of Julius Caesar the pagus Lemovicinu covered the county now comprised in the departments of Haute-Vienne, Corrèze and Creuse, with the arrondissements of Confolens in Charente and Nontron in Dordogne. These limits it is retained until the 18th century. In 1884 the department of the district of Limoges (except a small part cut off in 1317 to form that of Tulle) until 1790. The break-up into great fiefs in the 10th century, however, tended rapidly to disintegrate the province, until at the close of the 12th century Limousin embraced only the viscounties of Limoges, Turenne and Comborn, with a few ecclesiastical lordships, corresponding roughly to the present arrondissements of Limoges and Saint-Yriez in Haute-Vienne and part of the arrondissements of Brive, Tulle and Usse in Corrèze. In the 17th century Limousin, thus constituted, had become no more than a small government.

Limousin takes its name from the Lemovices, a Gallic tribe whose county was included by Augustus in the province of Aquitania Magna. Politically its history has little of separate interest; it shared in general the vicissitudes of Aquitaine, whose dukedoms from 168 onwards were its hereditary wards, and by the counts of Poitiers, until the French kings succeeded in asserting their direct overlordship. It was, however, until the 14th century, the centre of a civilization of which the enamelling industry (see Enamel) was only one expression. The Limousin dialect, now a mere patois, was regarded by the troubadours as the purest form of Provençal.

See A. Lereux, Géographie et histoire du Limousin (Limoges, 1892). Detailed bibliography in Chevalier, Répertoire des sources. Topo-bibliogr. (Monthbèard, 1902), 2. ii. 56.

LIMPOPO, or CROCODILE, a river of S.E. Africa over 1000 m. in length, next to the Zambezi the largest river of Africa entering the Indian Ocean. Its head streams rise on the northern slopes of the Witwatersrand less than 300 m. due W. In its mouth to the site till the river makes a great semicircular sweep across the high plateau first N.W. then N.E. and finally S.E. It is joined in its course by the Marico and Notwani, streams which rise on the westward continuation of the Witwatersrand, the ridge forming the water-parting between the Vaal and the Limpopo basins. For a great part of its course the Limpopo forms the north-west and north frontiers of the Transvaal. Its banks are well wooded and present many picturesque views. In descending the escarpment of the plateau the river passes through rocky ravines, piercing the Zoutpansberg near the north-east corner of the Transvaal at the Toli Azimé Falls. In the low country it receives its chief affluent, the Olifants river (450 m. long), which, rising in the high veld of the Transvaal east of the sources of the Limpopo, takes a more direct N.E. course than the main stream. The Limpopo enters the ocean in 25° 15' S. The mouth, about 1000 ft. wide, is obstructed by sand-banks. In the rainy season the Limpopo loses a good deal of its water in the swampy region along its lower course. High-water level is 24 ft. above low-water level, when the depth in the shallowest part does not exceed 3 ft. The river is navigable all the year round by slow-draught vessels from its mouth for about 100 m., to a spot known as Gungunyanza's Ford. In flood time there is water communication south with the river Komati (q.v.). At this season stretches of the Limpopo above Gungunyanza's Ford are navigable. The river valley is generally unhealthy.

The basin of the Limpopo includes the northern part of the Transvaal, the eastern portion of Bechuanaland, southern Matabeleland and a large area of Portuguese territory north of Delagoa Bay. In the tributary, the district is nearly half the area of the country, and many other affluents of the Macloutsi and Shashi to the Tuli are the most distant north-west feeders. In this direction the Matoppos and other hills of Matabeleland separate the Limpopo basin from the plains of Bechuanaland. A little above the Tuli confluence is the Mod's Drift, the usual crossing-place from the northern Transvaal into Matabeleland. Among the streams which, flowing north through the Transvaal, join the Limpopo is the Nylostroom, so named by Bowers in the belief that they had reached the river Nile. In the coast region the river has one considerable affluent from the north, the Chengane, which is navigable for some distance.

The Limpopo is a river of many names. In its upper course called the Crocodile that name is also applied to the whole river, which figures on old Portuguese maps as the Our (or Oira) and Bembe. Though claiming the territory through which it ran the Portuguese made no attempt to trace the river. This was first done by Captain E. Tolgo, who in 1859, starting from the Tati goldfields, sought to open a road to the sea via the Limpopo. He voyaged down the river from the Shashi confluence to the Toli Azimé Falls, which he discovered, following the stream thence on foot to the low country. The limits of the basin were explored 1858-1869 by another British traveller—St Vincent Whitted Errsikine. It was first navigated by a sea-going craft in 1884, when G. A. Chaddock of the British mercantile service succeeded in crossing the bar, while its mouth was accurately surveyed by the Royal Navy in 1865-1896. At the junction of the Louts, one of the Bechuanaland affluents, with the Limpopo, are ruins of the period of the Zimbabwe.

LINACRE, or LINAKER, THOMAS (c. 1460-1524), English humanist and physician, was probably born at Canterbury. His parentage or descent nothing certain is known. He was possibly educated by his uncle, Henry Linacre, by then under the direction of William Celling (William Tilly of Selling), who became prior of Canterbury in 1472. Celling was an ardent scholar, and one of the earliest in England who cultivated Greek learning. From him Linacre must have received his first incentive to this study. Linacre entered Oxford about the year 1480, and in 1484 was elected a fellow of All Souls' College. Shortly afterwards he visited Italy in the train of Celling, who was sent by Henry VIII. as an envoy to the papal court, and he accompanied his patron as far as Bologna. There he became the pupil of Angelo Poliziano, and afterwards shared the instruction which that great scholar imparted at Florence to the sons of Lorenzo de' Medici. The younger of these princes became Pope Leo X., and was in after years mindful of his old companionship with Linacre. Among his other teachers and friends in Italy were Demetrius Chalcondylas, Hermolaus Barbarus, Julius Romanus the printer of Venice, and Nicolas Leoncinus of Vicenza. Linacre took the degree of doctor of medicine with great distinction at Padua. On his return to Oxford, full of the learning and imbued with the spirit of the Italian Renaissance, he formed one of the brilliant circle of Oxford scholars, including John Colet, William Grocyn and William Latimer, who are mentioned with so much warm eulogy in the letters of Erasmus.

Linacre does not appear to have practised or taught medicine in Oxford. About the year 1501 he was called to court as tutor of the young prince Arthur. On the accession of Henry VIII. he was appointed the king's physician, an office at that time of considerable influence and importance, and practised medicine in London, having among his patients most of the great statesmen and prelates of the time, as Cardinal Wolsey, Archbishop Warham and Bishop Fox.

After some years of professional activity, and when in advanced life, Linacre received priest's orders in 1520, though he had for some years previously held several clerical benefices. There is no doubt that his ordination was connected with his retirement from active life. Literary labours, and the cares of the foundation which owed its existence chiefly to him, the Royal College
of Physicians, occupied Linacre's remaining years till his death on the 20th of October 1524.

Linacre was more of a scholar than a man of letters, and rather a man of learning than a scientific investigator. It is difficult now to judge of his practical skill in his profession, but it was evidently highly esteemed in his own day. He took no part in political or theological questions, and died too soon to have to declare himself on either side in the formidable controversies which were even in his lifetime beginning to arise. But his career as a scholar was one eminently characteristic of the early period in the history of learning through which he lived. He was one of the first Englishmen who studied Greek in Italy, whence he brought back to his native country and his own university the lessons of the "New Learning." His teachers were some of the greatest scholars of the day. Among his pupils was—Erasmus—whose name alone would suffice to preserve the memory of his instructor in Greek, and others of note in letters and politics, such as Sir Thomas More, Prince Arthur and Queen Elizabeth. He was a man of letters, a man of science, and his scholar friends were his intimate friends, and he was esteemed by a still wider circle of literary correspondents in all parts of Europe.

Linacre's literary activity was displayed in two directions, in pure scholarship and in translation from the Greek. In the domain of scholarship he was known by the rudiments of (Latin) grammar (Pregnymatara Grammatices vulgaris), composed in English, a revised version of which was made for the use of the Princess Mary, and translated into Latin by John Roper. He also wrote a work on Latin composition, De emendata structura Latini sermonis, which was published in London in 1524 and many times reprinted on the continent of Europe.

Linacre's only medical works were his translations. He desired to make the works of Galen (and indeed those of Aristotle also) accessible to all readers of Latin. What he effected in the case of the first, though not trifling in itself, is incomparably as compared with the whole mass of Galen's writings, and of his translations from Aristotle, some of which are known to have been completed, nothing has survived. The following are the works of Galen translated by Linacre: (1) De sanitate tuenda, printed at Paris in 1515; (2) De institutione medendi, by Caius; (3) De differentiis et de Inequitati Intemperie (Cambridge, 1521); (4) De naturalibus facultatibus (London, 1523); (5) De symptomatum differentiis et causis (London, 1524); (6) De pulsuum Usu (London, without date). For the first he translated the original Latin of the medical treatise of Prorus, De sphæra, which was printed at Venice by Aldus in 1499. The accuracy of these translations and their elegance of style were universally admitted. They have been generally accepted, and the standard versions of those parts of Galen's writings, and frequently reprinted, either as a part of the collected works or separately.

But the most important service which Linacre conferred upon his own country was the sleeve of medical education. Linacre was chiefly owing the foundation by royal charter of the College of Physicians in London, and he was the first president of the new college, which he further aided by conveying to it his own house, and he left it to the college in the gift of the crown. He obtained from the king letters patent for the establishment of readerships in medicine at Oxford and Cambridge, and placed valuable estates in the hands of trustees for their enjoyment. Two readerships were founded in Linacre's name at Oxford in St John's College, Cambridge, but owing to neglect and bad management of the funds, they fell into uselessness and obscurity. The Oxford foundation was revived by the university commissions in 1842; the Cambridge foundation, in all probability, has been neglected. Posterity has done justice to the generosity and public spirit which prompted these foundations; and it is impossible not to recognize a strong constructive genius in the scheme of the College of Physicians, by which the college, when it was not the first organized the medical profession in England, but impressed upon it for some centuries the stamp of its own individuality.

The intellectual fastidiousness of Linacre, and his habits of minute accuracy were, as Erasmus suggests, the chief cause why he left no account of his life. Nevertheless it will be difficult to justify by any extant work the extremely high reputation which he enjoyed among the scholars of his time. His Latin style was so much admired that, according to the flattering eulogium of Erasmus, he could write Latin in the best style of the Second Latin. Indeed he had before spoken Greek; and even Aristotle displayed a grace which he hardly attained to in his native tongue. Erasmus praises also Linacre's critical judgment ("vir non ex acti tamit sed severi judicii") and his knowledge of Greek. Although he was more distinguished as a grammarian or a rhetorician. Of Greek he was regarded as a consummate master; and he was equally eminent as a "philosopher," that is, as learned in the works of the ancient philosophers and naturalists. In this there may have been some exaggeration; but all have acknowledged the elevation of Linacre's character, and the fine moral qualities summed up in the epitaph written by John Cairis; "Ferox dolosque mire pereosus; fidus amicis; omnibus ordinibus justa carus."

The materials for Linacre's biography constitute a large extent contained in the older biographical collections of George Lilly (in Paulus Jovius, Descriptio Britanniae), Bale, Leland and Pits, in Wood's Athenae Oxonienses and in the Biographia Britannica; and in the complete works of Linacre, by Dr Noble Johnson (London, 1835). Reference may also be made to Dr Munk's Roll of the Royal College of Physicians (2nd ed., London, 1878); and the Introduction, by Dr J. F. Payne, to a facsimile reprint of Linacre's works (Cambridge, 1881). With the exception of this treatise, none of Linacre's works or translations has been reprinted in modern times.

LINARES, an inland province of central Chile, between Talca on the N. and Nuble on the S., bounded E. by Argentina and W. by the province of Maule. Pop. (1895) 101,858; area, 3,942 sq. m. The river Maule forms its northern boundary and drains its northern and north-eastern regions. The province belongs partly to the great central valley of Chile and partly to the mountainous eastern slopes of the Andes, the S. Pedro volcano rising to a height of 11,800 ft. not far from the sources of the Maule. The northern part is fertile, as are the valleys of the Andean foothills, but arid conditions prevail throughout the central districts, and irrigation is necessary for the production of crops. The vine is cultivated to some extent, and good pasturage is found on the Andean slopes. The province is traversed from N. to S. by the Chilean Central railway, and the river Maule gives access to the small port of Constitucion, at its mouth. From Parral, near the southern boundary, a branch railway extends westward to Cauquenes, the capital of Maule. The capital, Linares, is centrally situated, on an open plain, about 20 m. S. of the river Maule. It had a population in 1895 of 7,337 (which an official estimate of 1902 reduced to 7,295). Parral (pop. 8,500 in 1895; est. 10,219 in 1902) is a railway junction and manufacturing town.

LINARES, a town of southern Spain, in the province of Jaen, along the northern foothills of the Sierra Morena, 1,375 ft. above sea-level, and 3 m. N.W. of the river Guadalimar. Pop. (1900) 38,245. It is connected by four branch railways with the important argentine lead mines on the north-west, and with the main railways from Madrid to Seville, Granada and the principal ports on the south coast. The town was greatly improved in the second half of the 19th century, when the town hall, bull-ring, theatre and many other handsome buildings were erected; it contains little of antiquarian interest save a fine fountain of Roman origin. Its population is chiefly engaged in the lead-mines, and in such allied industries as the manufacture of gunpowder, dynamite, match for blasting purposes, rope and the like. The mining plant is entirely imported, principally from England; and smelting, desilverizing and the manufacture of lead sheets, pipes, &c., are carried on by British firms, which also purchase most of the ore raised. Linares lead is unsurpassed in quality, but the output tends to decrease. There is a thriving local trade in wool and hides. Aldana, 6 m. S. is the village of Cazlona, which shows some remains of an ancient castle. The ancient mines some 5 m. N., which are now known as Los Pozos de Anibal, may possibly date from the 3rd century B.C., when this part of Spain was ruled by the Carthaginians.

LINCOLN, EARLS OF. The first earl of Lincoln was probably William de Roumare (c. 1005-1155), who was created earl about 1140, although it is possible that William de Albini, earl of Arundel, had previously held the earldom. Roumare's grandson, another William de Roumare (c. 1150-c. 1198), is sometimes called earl of Lincoln, but he was never recognized as such, and about 1148 King Stephen granted the earldom to one of his supporters, Gilbert de Gand (d. 1156), who was related to the former earl. After Gilbert's death the earldom was dormant for about sixty years; then in 1216 it was given to another Gilbert de Gand, and later it was claimed by the great earls of Chester, Ranulf, or Randolph, de Blundevill (d. 1242). From Ranulf the title to the earldom passed through his sister Hawise to the family of Lucy, John de Lucy (d. 1240) being made earl of Lincoln in 1232. He was son of Roger de Lucy (d. 1212), justiciar
of England and constable of Chester. It was held by the Lacy family until the death of Henry, the 3rd earl. Henry served Edward I. in Wales, France and Scotland, both as a soldier and a diplomatist. He went to France with Edmund, earl of Lancaster, in 1296, and when Edmund died in June of this year, succeeded him as commander of the English forces in Gascony; but he did not experience any great success in this capacity and returned to England early in 1298. The earl fought at the battle of Falkirk in July 1298, and took part in the subsequent conquest of Scotland. He was then employed by Edward to negotiate successfully with the papal legates and the king of Scotland. He married Elizabeth (d. 1321), daughter of King Edward II., and he was present at the death of his wife in July 1307. For a short time Lincoln was friendly with the new king, Edward II., and his favourite, Piers Gaveston; but quickly changing his attitude, he joined earl Thomas of Lancaster and the barons in rebellion; the king was captured. In 1310, the earl was appointed to the regency of the kingdom during the king's absence in Scotland in the same year. He died in London on the 5th of February 1311, and was buried in St Paul's Cathedral. He married Margaret (d. 1309), granddaughter and heiress of William Longsword, 2nd earl of Salisbury, and his only surviving child, Alice (d. 1352), became the wife of Thomas, Earl of Lancaster, who inherited his father-in-law's earldoms of Lincoln and Salisbury. Lincoln's Inn in London gets its name from the earl, whose London residence occupied this site. He founded Whalley Abbey in Lancashire, and built Denbigh Castle.

In 1349 Henry Plantagenet, earl (afterwards duke) of Lancaster, a nephew of Earl Thomas, was created earl of Lincoln; and when his grandson Henry became king of England as Henry IV., in 1399 the title merged in the crown. In 1467 John de la Pole (c. 1455-1470), a nephew of Edward IV., was made earl of Lincoln, and the same dignity was conferred in 1525 upon Henry Brandon (1516-1545), son of Charles Brandon, duke of Suffolk. Both died without sons, and the next family to hold the earldom was that of the Clontons.

Edward Fiennes Clonton, 9th Lord Clonton (1512-1585), lord high admiral and the husband of Henry VIII.'s mistress, Elizabeth Blount, was created earl of Lincoln in 1572. Before his elevation he had rendered very valuable services both on sea and land to Edward VI., to Mary and to Elizabeth, and he was in the confidence of the leading men of these reigns, including William Cecil, Lord Burghley. From 1572 until the present day the title has been held by Clonton's descendants. In 1578 Henry Clonton, the 9th earl (1720-1764), succeeded his uncle Thomas Fiennes, 10th earl, but with the title of earl of Lincoln. In 1579 the title of earl of Lincoln has been the courtesy title of the eldest son of the duke of Newcastle.

LINCOLN, ABRAHAM (1809-1865), sixteenth president of the United States of America, was born on ‘Rock Spring’ farm, 3 m. from Hodgenville, in Hardin (now Larue) county, Kentucky, on the 12th of February 1809.1 His grandfather,2 Abraham Lincoln, settled in Kentucky about 1780 and was killed by Indians in 1784. His father, Thomas (1778-1817), was born in Rockingham (then Augusta) county, Virginia; he was hospital-able, shiftless, restless and unsuccessful, working now as a carpenter and now as a farmer, and could not read or write before his marriage, in Washington county, Kentucky, on the 12th of June 1806, to Nancy Hanks (1783-1818), who was, like him, a native of Virginia, but had much more strength of character and native ability, and seemed to have been, in Lincoln's birthday is a legal holiday in California, Colorado, Connecticut, Delaware, Florida, Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Montana, Nebraska, New Jersey, New York, North Dakota, Pennsylvania, South Dakota, Utah, Washington, West Virginia and Wyoming.

1 Samuel Lincoln (c. 1615-1690), the president's first American ancestor, son of Edward Lincoln, gent., of Hingham, Norfolk, emigrated to Massachusetts in 1637 as apprentice to a weaver and settled with two older brothers in Hingham, Mass. His son and grandson were weavers; the grandson Mordecai (1688-1736) moved to Chester county, Pennsylvania. Mordecai's son John (1711-1773), a weaver, settled in what is now Rockingham county, Va., and was the president's great-grandfather.

intellect and character, distinctly above the social class in which she was born. The Lincolns had removed from Elizabethtown, Hardin county, their first home, to the Rock Spring farm, only a short time before Abraham's birth; about 1823 they removed to a farm of 238 acres on Knob Creek, about 6 m. from Hodgenville; and in 1816 they crossed the Ohio river and settled on a quarter-section, 1/4 m. E. of the present village of Gentryville, in Spencer county, Indiana. There Abraham's mother died on the 5th of October 1818. In December 1840 his father married, at his old home, Elizabethtown, Mrs Sarah (Bush) Johnston (d. 1890), whom he had courted years before, whose thrift greatly improved conditions in the home, and who exerted a great influence over her stepson. Spencer county was still a wilderness, and the boy grew up in pioneer surroundings, living in a rude log-cabin, enduring many hardships and knowing only the primitive manners, conversation and ambitions of sparsely settled backwoods communities. Schools were rare, and teachers qualified only to impart the merest rudiments. “Of course when I came of age I did not know much,” wrote he years afterward, “still somehow I could read, write and cipher to the rule of three, but that was all. I have not been to school since. The little advance I now have upon this store of education I have picked up from time to time under the pressure of necessity.” His entire schooling, in five different schools, amounted to less than a twelvemonth; but he became a good spell and an excellent penman. His own mother taught him to read, and his stepmother urged him to study. He read and re-read in early boyhood the Bible, Aesop, Robinson Crusoe, Pilgrim's Progress, Weems's Life of Washington and a history of the United States; and later read every book he could borrow from the neighborhood. Burns, Shakespeare, and company became his early friends. He wrote rude, coarse satires, crude verse, and compositions on the American government, temperance, &c. At the age of seventeen he had attained his full height, and began to be known as a wrestler, runner and lifter of great weights. When nineteen he made a journey as a hired hand on a flatboat to New Orleans.

In March 1830 his father emigrated to Macon county, Illinois (near the present Decatur), and soon afterward removed to Coles county. Being now twenty-one years of age, Abraham hired himself to Denton Offutt, a migratory trader and storekeeper then of Sangamon county, and he helped Offutt to build a flatboat and float it down the Sangamon, Illinois and Mississippi rivers to New Orleans. In 1831 Offutt made him clerk of his store, which was located on a river bluff in Sangamon county. In 1832 Offutt returned to his farm in Menard county; this gave him moments of leisure to devote to self-education. He borrowed a grammar and other books, sought explanations from the village schoolmaster and began to read law. In this frontier community law and politics claimed a large proportion of the stronger and the more ambitious men; the law early appealed to Lincoln and his general popularity encouraged him as early as 1832 to enter politics. In this year Offutt failed and Lincoln was thus left without employment. He became a candidate for the Illinois House of Representatives; and on the 9th of March 1832 issued an address “To the people of Sangamon county” which betokens talent and education far beyond mere ability to “read, write and cipher,” though in its preparation he seems to have had the help of a friend. Before the election the Black Hawk Indian War broke out; Lincoln volunteered in one of the Sangamon county companies on the 21st of April and was elected captain by the members of the company. It is said that the oath of allegiance was administered to Lincoln at this time by Lieut. Jefferson Davis. The company, a part of the 4th Illinois, was mustered out after the five weeks' service for which it volunteered, and Lincoln re-enlisted as a private on the 29th of May, and was finally mustered out on the 16th of June by Lieut. Robert Anderson, who in 1861 commanded the Union troops at Fort Sumter. As captain Lincoln was twice in disgrace, once for firing a pistol near camp and again because nearly his entire company was intoxicated. He was in no battle, and always spoke lightly of his military record. He was defeated in his campaign for the legislature in
1832, partly because of his unpopular adherence to Clay and the American system, but in his own election precinct, he received nearly all the votes cast. With a friend, William Berry, he then bought a small country store, which soon failed chiefly because of the drunken habits of Berry and because Lincoln preferred to read and to tell stories—he early gained local celebrity as a story-teller—rather than sell; about this time he got hold of a set of Blackstone. In the spring of 1833 the store's stock was sold to satisfy its creditors, and Lincoln assumed the firm's debts, which he did not fully pay off for fifteen years. In May 1833, local friendship, disregarding politics, procured his appointment as postmaster of New Salem, but this paid him very little, and in the same year the county surveyor of Sangamon county opportunely offered to make him one of his deputies. He hastily qualified himself by study, and entered upon the practical duties of surveying farm lines, roads and town sites. "This, to use his own words, "procured bread, and kept body and soul together."

In 1834 Lincoln was elected (second of four successful candidates, with only 14 fewer votes than the first) a member of the Illinois House of Representatives, to which he was re-elected in 1836, 1838 and 1840, serving until 1842. In his announcement of his candidacy in 1836 he promised to vote for Hugh L. White of Tennessee (a vigorous opponent of Andrew Jackson in Tennessee politics) for president, and said: "I go for all sharing the privileges of the government who assist in bearing its burdens. Consequently, I go for admitting all whites to the right of suffrage, who pay taxes or bear arms (by no means excluding females)"—a sentiment frequently quoted to prove Lincoln a believer in woman's suffrage. In this election he led the poll in Sangamon county. In the legislature, like the other representatives of that county, who were called the "Long Nine," because of their stature, he worked for internal improvements, for which lavish appropriations were made, and for the division of Sangamon county and the choice of Springfield as the state capital, instead of Vandalia. He and his party colleagues followed Stephen A. Douglas in adopting the convention system, to which Lincoln had been strongly opposed. In 1837 with one other representative from Sangamon county, named Dan Stone, he protested against a series of resolutions, adopted by the Illinois General Assembly, expressing disapproval of the formation of abolition societies and asserting, among other things, that "the right of property in slaves is sacred to the slave holding states under the Federal Constitution"; and Lincoln and Stone put out a paper in which they expressed their belief that "the institution of slavery is founded on both injustice and bad policy, but that the progress of abolition in the free states tends to increase these and abate its evils," "that the Congress of the United States has no power under the Constitution to interfere with the institution of slavery in the different states," "that the Congress of the United States has the power, under the Constitution, to abolish slavery in the District of Columbia, but that the power ought not to be exercised unless at the request of the people of the District." Lincoln was very popular among his fellow legislators, and in 1838 and in 1840 he received the complimentary vote of his minority colleagues for the speakership of the state House of Representatives. In 1842 he declined a renomination to the state legislature and attempted unsuccessfully to secure a nomination to Congress. In the same year he became interested in the Washingtonian temperance movement.

In 1846 he was elected a member of the National House of Representatives by a majority of 15 over his Democratic opponent, Peter Cartwright, the Methodist preacher. Lincoln was the only Whig member of Congress elected in Illinois in 1846. In the House of Representatives on the 22nd of December 1847 he introduced the "Spot Resolutions," which quoted statements in the president's messages of the 11th of May 1846 and the 7th and 8th of December that Mexican troops had invaded the territory of the United States, and asked the president to tell the precise "spot" of invasion; he made a speech on these resolutions in the House on the 12th of January 1848. His attitude toward the war and especially his vote for George Ashmun's amendment to the supply bill at this session, declaring that the Mexican War was "unnecessarily and unconstitutionally commenced by the President," greatly displeased his constituents. He later introduced a bill regarding slavery in the District of Columbia, which (in accordance with his statement of 1837) was to be submitted to the vote of the District for approval, and which provided for compensated emancipation, forbade the bringing of slaves into the District of Columbia, except by government officials from slave states, and the selling of slaves away from the District, and arranged for the emancipation after a period of apprenticeship of all slave children born after the 1st of January 1836. While he was in Congress he voted repeatedly for the principle of the Wilmot Proviso. At the close of his term in 1848 he declined an appointment as governor of the newly organized Territory of Oregon and for a time worked, without success, for an appointment as Commissioner of the General Land Office. During the presidential campaign he made speeches in Illinois, and in Massachusetts he spoke before the Whig State Convention at Worcester on the 12th of September, and in the next ten days at Lowell, Dedham, Roxbury, Chelsea, Cambridge and Boston. He had become an eloquent and influential public speaker, and in 1840 and 1844 was a candidate on the Whig ticket for presidential elector.

In 1834 his political friend and colleague John Todd Stuart (1807-1885), a lawyer in full practice, had urged him to fit himself for the bar, and had lent him text-books; and Lincoln, working diligently, was admitted to the bar in September 1836. In April 1837 he quitted New Salem, and removed to Springfield, which was the county-seat and was soon to become the capital of the state, to begin practice in a partnership with Stuart, which was terminated in April 1841; from that time until September 1843 he was junior partner to Stephen Trigg Logan (1800-1880), and from 1843 until his death he was senior partner of William Henry Herndon (1812-1891). Between 1849 and 1854 he took little part in politics, devoted himself to the law and became one of the leaders of the Illinois bar. His small fees—he once charged $3-50 for collecting an account of nearly $600-oo—his frequent refusals to take cases which he did not think right and his attempts to prevent unnecessary litigation have become proverbial. Judge David Davis, who knew Lincoln on the Illinois circuit and whom Lincoln made in October 1862 an associate justice of the Supreme Court of the United States, said that he was "great both at nisi prius and before an appellate tribunal." He was an excellent cross-examiner, whose candid friendliness of manner often succeeded in eliciting important testimony from unwilling witnesses. Among Lincoln's most famous cases were: one (Bailey v. Cromwell, Ill. 111; frequently cited) before the Illinois Supreme Court in July 1841 in which he argued against the validity of a note in payment for a negro girl, adding the Ordinance of 1787 and other authorities; a case (tried in Chicago in September 1837) for the Rock Island railway, tried for damages by the owners of a steamboat sunk after collision with a railway bridge, a trial in which Lincoln brought to the service of his client a surveyor's knowledge of mathematics and a riverman's acquaintance with currents and channels, and argued that crossing a stream by bridge was as truly a common right as navigating it by boat, thus contributing to the success of Chicago and railway commerce in the contest against St Louis and river transportation; the defence (at Beardstown in May 1858) on the charge of murder of William ("Duff") Armstrong, son of one of Lincoln's New Salem friends, whom Lincoln freed by controversy with the help of an almanac the testimony of a crucial witness that between 10 and 11 o'clock at night he had seen by moonlight the defendant strike the murderous blow—this dramatic incident is described in Edward Eggleston's novel, The Graysons; and the defence on the charge of murder (committed in August 1859) of "Peachy" Harrison, a grandson of Peter Cartwright, whose testimony was used with great effect.

From law, however, Lincoln was soon drawn irresistibly back into politics. The slavery question, in one form or another,
had become the great overshadowing issue in national, and even in state politics; the abolition movement, begun in earnest by W. L. Garrison in 1831, had stirred the conscience of the North, and had had its influence even upon many who strongly deprecated its extreme radicalism; the Compromise of 1850 had failed to silence sectional controversy, and the Fugitive Slave Law, which was one of the compromise measures, had throughout the North been bitterly assailed and to a considerable extent had been nullified by state legislation; and finally in 1854 the slavery agitation was fomented by the passage of the Kansas-Nebraska Act, which repealed the Missouri Compromise and gave legislative sanction to the principle of "popular sovereignty"—the principle that the inhabitants of each Territory as well as of each state were to be left free to decide for themselves whether or not slavery was to be permitted therein. In enacting this measure Congress had been dominated largely by one man—Stephen A. Douglas of Illinois—then probably the most powerful figure in national politics. Lincoln had early put himself on record as opposed to slavery, but he was never technically an abolitionist; he allied himself rather with those who believed that slavery should be fought within the Constitution, that, though it could not be constitutionally interfered with in individual states, it should be excluded from territory over which the national government had jurisdiction. In this, as in other things, he was eminently clear-sighted and practical. Already he had shown his capacity as a forcible and able debater; aroused to new activity upon the passage of the Kansas-Nebraska Bill, which he regarded as a gross breach of political faith, he now entered upon public discussion with an earnestness and force that by common consent gave him leadership in Illinois of the opposition, which in 1854 elected a majority of the legislature; and it gradually became clear that he was the only man who could be opposed in debate to the powerful and adroit Douglas. He was elected to the state House of Representatives, from which he immediately resigned to become a candidate for United States senator from Illinois, to succeed James Shields, a Democrat; but five opposition members, of Democratic antecedents, refused to vote for Lincoln on the second ballot he received 47 votes—50 being necessary to elect—and he turned the votes which he controlled over to Lyman Trumbull, who was opposed to the Kansas-Nebraska Act, and thus secured the defeat of Joel Aldrich Matteson (1808-1883), who favoured this act and who on the eighth ballot had received 47 votes to 55 for Trumbull and 15 for Lincoln. The various anti-Nebraska elements came together, in Illinois as elsewhere, to form a new party at a time when the old parties were disintegrating; and in 1856 the Republican party was formally organized in the state. Lincoln before the state convention at Bloomington of all opponents of the anti-Nebraska legislation (the first Republican state convention in Illinois) made on the 26th of May a notable address known as the "Lost Speech." The National Convention of the Republican Party in 1856 cast 110 votes for Lincoln as its vice-presidential candidate on the ticket with Fremont, and he was on the Republican electoral ticket of this year, and made effective campaign speeches in the interest of the new party. The campaign in the state resulted substantially in a drawn battle, the Democrats gaining a majority in the state for president, while the Republicans elected the governor and state officers. In 1858 the term of Douglas in the United States Senate was expiring, and he sought re-election. On the 16th of June 1858 by unanimous resolution of the Republican state convention Lincoln was declared "the first and only choice of the Republicans of the United States Senate as the successor of Stephen A. Douglas" to whom it was "to succeed." Lincoln, addressing the convention which nominated him, gave expression to the following bold prophecy:

"A house divided against itself cannot stand. I believe this Government cannot endure permanently half slave and half free. I do not expect the Union to be dissolved—I do not expect the house to fail—but I do expect it will cease to be divided. It will become all one thing or all the other. Either the opponents of slavery will arrest the further spread of it, and place it where the public mind shall rest in the belief that it is in course of ultimate extinction; or its advocates will push it forward, till it shall become alike lawful in all the states, old as well as new—North as well as South."

In this speech, delivered in the state House of Representatives, Lincoln charged Pierce, Buchanan, Taney and Douglas with conspiracy to secure the Dred Scott decision. Yielding to the wishes of his party friends, on the 24th of July, Lincoln challenged Douglas to a joint public discussion on the slavery issue. A meeting of delegates was held at seven designated places in the state. The first meeting was at Ottawa, La Salle County, about 90 m. south-west of Chicago, on the 21st of August. At Freeport, on the Wisconsin boundary, on the 27th of August, Lincoln answered questions put to him by Douglas, and by his questions forced Douglas "to betray the South" by his enunciation of the "Freeport heresy," that, no matter what the character of Congressional legislation or the Supreme Court's decision "slavery cannot exist a day or an hour anywhere unless it is supported by local police regulations."

This adroit attempt to reconcile the principle of popular sovereignty with the Dred Scott decision, though it undoubtedly helped Douglas in the immediate fight for the senatorship, necessarily alienated his Southern supporters and assured his defeat, as Lincoln foresaw it must, in the presidential campaign of 1860. The other debates were: at Jonesboro, in the southern part of the state, on the 24th of September; at Springfield, on the 15th of October; at Galesburg (Oct. 7) and Quincy (Oct. 13) and Alton (Oct. 15). In these debates Douglas, the champion of his party, was over-matched in clearness and force of reasoning, and lacked the great moral earnestness of his opponent; but he dexterously extricated himself time and again from difficult argumentative positions, and retained sufficient support to win the immediate prize. At the November election the Republican vote was 126,084, the Douglas Democratic vote was 121,940 and the Lecompton (or Buchanan) Democratic vote was 5091; but the Democrats, through a favourable apportionment of representative districts, secured a majority of the legislature (Senate: 14 Democrats, 11 Republicans; House: 40 Democrats, 35 Republicans), which re-elected Douglas. Lincoln's speeches in this campaign won him a national fame. In 1859 he made two speeches in Ohio—one at Columbus on the 16th of September criticising Douglas's paper in the September Harper's Magazine, and one at Cincinnati on the 17th of September, which was addressed to Kentuckians,—and he spent a few days in Kansas, speaking in Elwood, Troy, Doniphan, Atchison and Leavenworth, in the first week of December. On the 27th of February 1860 in Cooper Union, New York City, he made a speech (much the same as that delivered in Elwood, Kansas, on the 1st of December) which made him known favourably to the leaders of the Republican party in the East and which was a careful historical study criticizing the statement of Douglas in one of his speeches in Ohio that "our fathers when they framed the government under which we live understood this question [slavery] just as well and even better than we do now," and Douglas's contention that "the fathers made the country (and intended that it should have) a free country. Lincoln pointed out that the majority of the members of the Constitutional Convention of 1787 opposed slavery and that they did not think that Congress had no power to control slavery in the Territories. He spoke at Concord, 1

Douglas and Lincoln first met in public debate (four on a side) in Springfield in December 1839. They met repeatedly in the campaign of 1840. In 1852 Lincoln attempted with little success to reply to a speech made by Douglas in Richmond. On the 4th of October 1854 in Springfield, in reply to a speech on the Nebraska question, Douglas delivered a remarkable speech four hours long, to which Douglas replied on the next day; and in the fortnight immediately following Lincoln attacked Douglas's record again at Bloomington and at Peoria. On the 6th of June 1858 in Peoria, Lincoln delivered his famous "House Divided" speech, and on the 16th of July at Springfield the two candidates met in debate. Douglas's speech of the 12th in which he made his doctrine of popular sovereignty to suit the Dred Scott decision. Before the actual debate in 1858 Douglas made a speech in Chicago on the 9th of July, to which Lincoln replied the next day: Douglas spoke at Bloomington on the 16th of July and Lincoln answered him in Springfield on the 17th.
Manchester, Exeter and Dover in New Hampshire, at Hartford (5th March), New Haven (6th March), Woosneck (8th March) and Newburgh (South March). The Illinois State Convention of the Republican party, held at Decatur on the 9th and 10th of May 1860, amid great enthusiasm declared Abraham Lincoln its first choice for the presidential nomination, and instructed the delegation to the National Convention to cast the vote of the state as a unit for him.

The Republican national convention, which made “No Extension of Slavery” the essential part of the party platform, met at Chicago on the 16th of May 1860. At this time William H. Seward was the most conspicuous Republican in national politics, and Salmon P. Chase had long been in the forefront of the political contest against slavery. Both had won greater national fame than had Lincoln, and, before the convention met, each hoped to be nominated for president. Chase, however, had little chance, and the contest was virtually between Seward and Lincoln, and by whom was considered more “available,” because it was thought that he could (and Seward could not) secure the vote of certain doubtful states. Lincoln’s name was presented by Illinois and secured by Indiana. At first Seward had 112 votes and Lincoln 50!

On the first ballot Lincoln received only 102 votes to 173½ for Seward. On the second ballot Lincoln received 181 votes to Seward’s 1843. On the third ballot the 50½ votes formerly given to Simon Cameron1 were given to Lincoln, who received 23½ votes to 180 for Seward, and without taking another ballot enough votes were changed to make Lincoln’s total 354 (223 being necessary for a choice) and the nomination was then made unanimous.

Hannibal Hamlin, of Maine, was nominated for the vice-presidency. The convention was singularly tumultuous and noisy; loud claquers were hired by both Lincoln’s and Seward’s managers. During the campaign Lincoln remained in Springfield, making few speeches and writing practically no letters for publication. The campaign was unusually animated—only the Whig campaign for William Henry Harrison in 1840 is comparable to it; there were great torchlight processions of “wide-awake” clubs, which did “rail- fence,” or zigzag, marches, and carried rails in honour of their candidate, the “rail-splitter.” Lincoln was selected by a popular vote of 1,866,452 to 1,757,157 for Douglas, 843,953 for Breckinridge and 590,631 for Bell—as the combined vote of his opponents was so much greater than his own he was often called “the minority president”; the electoral vote was: Lincoln, 180; John C. Breckinridge, 72; John Bell, 39; Stephen A. Douglas, 12. On the 4th of March 1861 Lincoln was inaugurated as president. (For an account of his administration see United States: History.)

During the campaign radical leaders in the South frequently asserted that the success of the Republicans at the polls would mean that the rights of the slave-holding states under the Federal constitution, as interpreted by them, would no longer be respected by the North, and that, if Lincoln were elected, it would be the duty of these slave-holding states to secede from the Union. There was much opposition in these states to such a course, but the secessionists triumphed, and by the time President Lincoln was inaugurated, South Carolina, Georgia, Alabama, Florida, Mississippi, Louisiana and Texas had withdrawn from the Union. A provisional government under the designation “The Confederate States of America,” with Jefferson Davis as president, was organized by the seceding states, which seized by force nearly all the forts, arsenals and public buildings within their limits. Great division of sentiment existed in the North, whether in this emergency acquiescence or coercion was the preferable policy. Lincoln’s inaugural address declared the Union perpetual and acts of secession void, and announced the determination of the government to defend its authority, and to hold forts and places yet in its possession. He disclaimed any intention to invade, subjugate or oppress the seceding states. “You can have no conflict,” he said, “without being yourselves the aggressors.” Fort Sumter, in Charleston harbour, had been besieged by the secessionists since January 19, 1861, and it being no longer tenable. On the 8th of April, through starvation, Lincoln sent the besiegers official notice on the 8th of April that a fleet was on its way to carry provisions to the fort, but that he would not attempt to reinforce it unless this effort were resisted. The Confederates, however, immediately ordered its reduction, and after a thirty-four hours’ bombardment the garrison capitulated on the 13th of April 1861. (For the military history of the war, see American Civil War.)

With civil war thus provoked, Lincoln, on the 15th of April, by proclamation called 75,000 three months’ militia under arms, and on the 4th of May ordered the further enlistment of 64,748 soldiers and 18,000 seamen for three years’ service. He instituted by proclamation of the 19th of April a blockade of the Southern ports, took effective steps to extemporize a navy, convened Congress in special session (on the 4th of July), and asked for legislation and authority to make the war “short, sharp and decisive.” The country responded with enthusiasm to his summons and suggestions; and the South on its side was successful.

The slavery question presented vexatious difficulties in conducting the war. Congress in August 1861 passed an act (approved August 6th) confiscating rights of slave-owners to slaves employed in hostile service against the Union. On the 30th of August General Fremont by military order declared martial law and confiscation against active enemies, with freedom to their slaves, in the State of Missouri. Believing that under existing conditions such a step was both detrimental in present policy and unauthorized in law, President Lincoln directed him (2nd September) to modify the order to make it conform to the Confiscation Act of Congress, and on the 11th of September annulled the parts of the order which conflicted with this act. Strong political factions were instantly formed for and against military emancipation, and the government was hotly beset by antagonistic counsel. The Unionists of the border slave states were greatly alarmed, but Lincoln by his moderate conservatism held them to the military support of the government. Meanwhile he sagaciously prepared the way for the supreme act of state emancipation, which was the gathering national crisis already dimly foreshadowed. On the 6th of March 1862, he sent a special message to Congress recommending the passage of a resolution offering pecuniary aid from the general government to induce states to adopt gradual abolition of slavery. Promptly passed by Congress, the resolution produced no immediate result except in its influence on public opinion. A practical step, however, soon followed1. In April Congress passed and the president approved (6th April) an act emancipating the slaves in the District of Columbia, with compensation to owners—a measure which Lincoln had proposed when in Congress. Meanwhile slaves of loyal masters were constantly escaping to military camps. Some commanders excluded them altogether; others surrendered them on demand; while still others sheltered and protected them against their owners. Lincoln tolerated this latitude as falling properly within the military discretion pertaining to local army operations. A new case, however, led his office to intervene. On the 8th of May 1862 General David Hunter, commanding in the limited areas gained along the southern coast, issued a short order declaring his department under martial law, and adding—“Slavery and martial law in a free country are altogether incompatible. The persons in these three States—Georgia, Florida and South Carolina—heretofore

1 Without Lincoln’s knowledge or consent, the managers of his candidacy before the convention bargained for Cameron’s votes by promising to Cameron a place in Lincoln’s cabinet, should Lincoln be elected. Cameron became Lincoln’s first secretary of war.

2 In November 1861 the president drafted a bill providing (1) that all slaves more than thirty-five years old in the state of Delaware should immediately become free; (2) that all children of slave parents, if born after the passage of the act, should be free; and that all others should be free on attaining the age of thirty-five or after the 1st of January 1893, except for terms of apprenticeship; and (4) that the national government should pay to the state of Delaware $23,200 a year for twenty-one years. But this bill, which Lincoln had hoped would introduce a system of “compensated emancipation,” was not approved by the legislature of Delaware, which considered it in February 1862.
held as slaves are, therefore, declared for ever free." As soon
as this order, by the slow method of communication by sea,
reached the newspapers, Lincoln (May 19) published a procla-
amtion declaring it void; adding further, "Whether it be com-
petent for me as commander-in-chief of the army and navy to
declare the slaves of any state or states free, and whether at any
time or in any case it shall have become a necessity indispens-
able to the maintenance of the government to exercise such supposed
power, are questions which under my responsibility I reserve
to myself, and which I cannot feel justified in leaving to the
decision of commanders in the field. These are totally different
questions from those of police regulations in armies or camps."
But in the same proclamation Lincoln recalled to the public
his own proposal and the assent of Congress to compensate states
which would adopt voluntary and gradual abolishment. "To the
people of these states now," he added, "I must earnestly
appeal. I do not argue. I beseech you to make the argument
for yourselves. You cannot, if you would, be blind to the signs
of the times." Meanwhile the anti-slavery sentiment of the
North constantly increased. Congress by express act (approved
on the 19th of June) prohibited the existence of slavery in all
territories outside of states. On July the 12th the president
called the representatives of the border slave states to the
executive mansion, and once more urged upon them his proposal of
compensated emancipation. "If the war continues long," he
said, "as it must if the object be not sooner attained, the
institution in your states will be extinguished by mere friction
and abrasion—by the mere incidents of the war. It will be
gone, and you will have nothing valuable in lieu of it." Although
Lincoln's appeal brought the border states to no practical
decision—the representatives of these states almost without
exception opposed the plan—it served to prepare public opinion
for his final act. During the month of July his own mind
reached the virtual determination to give slavery its coup de
grâce; on the 17th he approved a new Confiscation Act, much
broader than that of the 6th of August 1861 (which freed only
those slaves in military service against the Union) and giving to
the president the power to employ persons of African descent for
the suppression of the rebellion; and on the 22nd he submitted
to his cabinet the draft of an emancipation proclamation sub-
stantially as afterward issued. Serious military reverses con-
strained him for the present to withhold it, while on the other hand
they served to increase the pressure upon him from anti-slavery
men. Horace Greeley having addressed a public letter to him
saying, "Your policy, your policy is to save the Union by
freeing the slaves of the rebels," the president replied on the 22nd
of August, saying, "My paramount object is to save the Union,
and not either to save or destroy slavery. If I could save the
Union without freeing any slave, I would do it; if I could save
it by freeing all the slaves, I would do it; and, if I could do it by
freeing some and leaving others alone, I would also do that."
Thus still holding back violent reformers with one hand, and
leading up halting conservatives with the other, he on the 13th
of September replied among other things to an address from a
delegation: "I do not want to issue a document that the whole
world will see must necessarily be inoperative like the pope's
bull against the comet. ... I view this matter as a practical war
measure, to be decided on according to the advantages or dis-
advantages it may offer to the suppression of the rebellion. ... I
have not decided against a proclamation of liberty to the
slaves, but hold the matter under advisement."

The year 1862 had opened with important Union victories.
Admiral A.H. Foote captured Fort Henry on the 6th of February,
and Gen. U.S. Grant captured Fort Donelson on the 16th of
February, and won the battle of Shiloh on the 6th and 7th
of April. Gen. A. E. Burnside took possession of Roanoke
island on the North Carolina coast (7th February). The famous
contest between the ironclads "Monitor" and "Merrimac"
(6th April), though indecisive, effectually stopped the career
of the Confederate vessel, which was later destroyed by the
Confederates themselves. (See HAMPTON ROADS.) Farragut,
with a wooden fleet, ran past the twin forts St Philip and Jackson,
compelled the surrender of New Orleans (26th April), and
gained control of the lower Mississippi. The succeeding three
months brought disaster and discouragement to the Union
army. McClellan's campaign against Richmond was made
abortive by his timorous generalship, and compelled the with-
drawal of his army. Pope's army, advancing against the same
city by another line, was beaten back upon Washington in defeat.
The tide of war, however, once more turned in the defeat
of Lee's invading army at South Mountain and Antietam in
Maryland on the 14th and on the 16th and 17th of September,
compelling him to retreat.

With public opinion thus ripened by alternate defeat and
victory, President Lincoln, on the 22nd of September 1862,
issued his preliminary proclamation of emancipation, giving
notice that on the 1st of January 1863, "all persons held as
slaves by any person or persons claiming their right to their
servitude, whereof they shall then be in rebellion against the United
States shall be then, thenceforward and for ever free." In his message
to Congress on the 1st of December following, he again urged
his plan of gradual, compensated emancipation (to be com-
pleted on the 1st of December 1900) "as a means, not in exclusion
of, but additional to, all others for restoring and preserving
the national authority throughout the Union." On the 1st
day of January 1863 the final proclamation of emancipation
was duly issued, designating the States of Arkansas, Texas,
Mississippi, Alabama, Florida, Georgia, South Carolina, North
Carolina, and certain portions of Louisiana and Virginia, as
"this day in rebellion against the United States," and pro-
claiming that, in virtue of his authority as commander-in-
chief, and as a necessary war measure for suppressing rebellion,
I do ordain and declare that all persons held as slaves within said
designated states and parts of states are and henceforward shall
be free," and pledging the executive and military power of the
government to maintain such freedom. The legal validity of
these proclamations was never pronounced upon by the national
courts; but their decrees gradually enforced by the march of
armies were soon recognized by public opinion to be practically
irreversible.1 Such dissatisfaction as they caused in the border
slave states died out in the stress of war. The systematic
enlistment of negroes and their incorporation into the army
by regiments, hitherto only tried as exceptional experiments,
were now pushed with vigour, and, being followed by several
conspicuous instances of their gallantry on the battlefield,
added another strong impulse to the sweeping change of popular
opinion. To the question, Lincoln in the winter session of 1863–1864
strongly supported a movement in Congress to abolish slavery by
constitutional amendment, but the necessary two-thirds vote of the
House of Representatives could not then be obtained. In his
annual message of the 6th of December 1864, he urged the im-
mediate passage of the measure. Congress now acted promptly:

1 It is to be noted that slavery in the border slave states was not
affected by the proclamation. The parts of Virginia and Louisiana
not affected were those then considered to be under Federal juris-
diction, comprising the part of Virginia (except the 48 which
became the separate state of West Virginia), and in Louisiana
13 parishes (including the parish of Orleans). As the Federal
Government did not, at the time, have jurisdiction over the rest
of the territory of the Confederate States, that really affected, some
writers have questioned whether the proclamation really emancipated
any slaves when it was issued. The proclamation had the most
important political effect in the North of rallying more than ever to
the support of the administration. The adoption of the 13th amend-
ment to the Federal Constitution in 1865 rendered unnecessary any
decision of the U.S. Supreme Court upon the validity of the proclamation.
amendment, and official proclamation made by President Johnson on the 18th of December 1865, declared it duly adopted.

The foreign policy of President Lincoln, while subordinate in importance to the great questions of the Civil War, nevertheless presented several difficult and critical problems for his decision. The arrest (8th of November 1861) by Captain Charles Wilkes of two Confederate envoys proceeding to Europe in the British steamer "Trident" seriously threatened peace with England. Public opinion in America almost unanimously sustained the act; but Lincoln, convinced that the rights of Great Britain as a neutral had been violated, promptly, upon the demand of England, ordered the liberation of the prisoners (26th of December). Later friendly relations between the United States and Great Britain, where, among the upper classes, there was a strong sentiment in favour of the Confederacy, were seriously threatened by the fitting out of Confederate privateers in British ports, and the Administration owed much to the skillful diplomacy of the American minister in London, Charles Francis Adams. A still broader foreign question grew out of Mexican affairs, when events culminating in the setting up of Maximilian of Austria as emperor under protection of French troops demanded the constant watchfulness of the United States. Lincoln's course was one of prudent moderation. France voluntarily declared that she sought in Mexico only to satisfy injuries done her and to overthrow or establish local government or to appropriate territory. The United States Government replied that, relying on these assurances, it would maintain strict non-intervention, at the same time openly avowing the general sympathy of its people with a Mexican republic, and that "their own safety and the cheerful destiny to which they aspire are intimately dependent on the continuance of free republican institutions throughout America." In the early part of 1863 the French Government proposed a mediation between the North and the South. This offer President Lincoln (on the 6th of February) declined to consider, Seward replying for him that it would only be entering into diplomatic discussion with the rebels whether the authority of the government should be renounced, and the country delivered over to disunion and anarchy.

The Civil War gradually grew to dimensions beyond all expectation. By January 1863 the Union armies numbered near a million men, and were kept up to this strength till the end of the struggle. The Federal war debt eventually reached the sum of $2,700,000,000. The fortunes of battle were somewhat fluctuating during the first half of 1863, but the beginning of July brought the Union forces decisive victories. The reduction of Vicksburg (4th of July) and Port Hudson (9th of July), with other operations, restored complete control of the Mississippi, severing the Southern Confederacy. In the east Lee had the second time marched his army into Pennsylvania to suffer a disastrous defeat at Gettysburg, on the 1st, 2nd and 3rd of July, though he was able to withdraw his shattered forces south of the Potomac. At the dedication of the battlefield at Gettysburg's center in November President Lincoln made the following oration, which has taken permanent place in a classic in American literature:

"Four score and seven years ago our fathers brought forth on this continent a new nation conceived in liberty and dedicated to the proposition that men are created equal. Women also have greatness in that they nation might live. It is altogether fitting and proper that we should do this. But, in a larger sense, we cannot dedicate, we cannot consecrate, we cannot hallow this ground. The brave men, living and dead who struggled here, have consecrated it, far above our poor power to add or detract. The world will little note nor long remember what we say here, but it can never forget what they did here. It is for us the living rather to be dedicated here to the unfinished work which they who fought there have thus far so nobly advanced. It is rather for us to be here dedicated to the great task remaining before us—that from these honored dead we take increased devotion to that cause for which they gave the last full measure of devotion—that we here highly resolve that these dead shall not have died in vain, that this nation under God shall have a new birth of freedom, and that government of the people, by the people, for the people, shall not perish from the earth."

In the unexpected prolongation of the war, volunteer enlistments became too slow to replenish the waste of armies, and in 1863 the government was forced to resort to a draft. The enforcement of the conscription created much opposition in various parts of the country, and led to a serious riot in the city of New York on the 13th-16th of July. President Lincoln executed the draft with all possible justice and forbearance, but refused every importunity to postpone it. It was made a special subject of criticism by the Democratic party of the North, which was now organizing itself on the basis of a discontinuance of the war, to endeavour to win the presidential election of the following year. Clement L. Vallandigham of Ohio, having made a violent public speech at Mt. Vernon, Oh., on the 1st of May against the war and military proceedings, was arrested on the 5th by General Burnside, tried by military commission, and sentenced on the 16th to imprisonment; a writ of habeas corpus had been refused, and the sentence was changed by the president to transportation beyond the military lines. By way of political defiance the Democrats of Ohio nominated Vallandigham for governor on the 11th of June. Prominent Democrats and a committee of the Convention having appealed for his release, Lincoln wrote two long letters in reply discussing the constitutional question, and declaring that in his judgment the president as commander-in-chief in time of rebellion or invasion holds the power and responsibility of suspending the privilege of the writ of habeas corpus, but offering to release Vallandigham if the committee will sign a declaration that rebellion exists, that an army and navy are constitutional means to suppress it, and that each of them would use his personal power and influence to prosecute the war. This liberal offer and their refusal to accept it counteracted all the political capital they hoped to make out of the case; and public opinion was still more powerfully influenced in behalf of the president's action, by the passage of the query which he propounded in one of his letters: "Must I shoot the simple-minded soldier boy who deserts, while I must not touch a hair of a wily agitator who induces him to desist?"

When the election took place in Ohio, Vallandigham was defeated by a majority of more than a hundred thousand.

Many unfounded rumours of a willingness on the part of the Confederate States to make peace were circulated to weaken the Union war spirit. To all such suggestions, up to the time of issuing his emancipation proclamation, Lincoln announced his readiness to stop fighting and grant amnesty, whenever they would submit to and maintain the national authority under the Constitution of the United States. Certain agents in Canada having in 1864 intimated that they were empowered to treat for peace, Lincoln, through Greeley, tendered them safe conduct to Washington. They were by this forced to confess that they possessed no authority to negotiate. The president thereupon sent them, and made public, the following standing offer:—

"To whom it may concern:

An emancipation proposition which embraces the restoration of peace, the integrity of the whole Union, and the abandonment of slavery, and which comes by and with an authority that can control the armies now at war against the United States, will be received and considered by the Executive Government of the United States; and will be met by liberal terms on substantial and collateral points, and the bearer or bearers thereof shall have safe conduct both ways. July 18, 1864."

"ABRAHAM LINCOLN."

A noteworthy conference on this question took place near the close of the Civil War, when the strength of the Confederacy was almost exhausted. F. P. Blair, senior, a personal friend of Jefferson Davis, acting solely on his own responsibility, was permitted to go from Washington to Richmond, where, on the 12th of January 1865, after a private and unofficial interview, Davis in writing declared his willingness to enter a conference "to secure peace to the two countries." Report being duly made to President Lincoln, he wrote a note (dated 18th January) consenting to receive any agent sent informally, "with the view of securing peace to the people of our common country." Upon
the basis of this latter proposition three Confederate commissioners (A. H. Stevens, J. A. C. Campbell and R. M. T. Hunter) finally came to Hampton Roads, where President Lincoln and Secretary Seward met them on the U.S. steam transport "River Queen," and on the 3rd of February 1865 an informal conference of four hours' duration was held. Private reports of the interview agree substantially in the statement that the Confederates proposed a cessation of the Civil War, and postponement of its issues for future adjustment, while for the present the belligerents should unite in a campaign to expel the French from Mexico, and to enforce the Monroe doctrine. President Lincoln, however, although he offered to use his influence to secure compensation by the Federal government to slave-owners for their slaves, if there should be "a voluntary abolition of slavery by the states," a stop was made to any such proposition. Congress, and the immediate representation of the southern states in Congress, refused to consider any alliance against the French in Mexico, and adhered to the instructions he had given Seward before deciding to personally accompany him. These formulated three indispensable conditions to adjustment: first, the restoration of the national authority throughout all the states; second, no receding by the executive of the United States on the slavery question; third, no cessation of hostilities short of an end of the war, and the disbanding of all forces hostile to the government. These terms the commissioners were not authorized to accept, and the interview ended without result.

As Lincoln's first presidential term of four years neared its end, the Democratic party gathered itself for a supreme effort. In November of 1864, it did not regard the day as a fight for the election. The bow of progress of the war, the severe sacrifice of life in campaign and battle, the enormous accumulation of public debt, arbitrary arrests and suspension of habeas corpus, the rigour of the draft, and the proclamation of martial law, furnished ample subjects of bitter and vindictive campaign oratory. A partisan coterie which surrounded M'Clellan loudly charged the failure of his Richmond campaign to official interference in his plans. Vallandigham had returned to his home in defiance of his banishment beyond military lines, and was leniently suffered to remain. The aggressive spirit of the party, however, pushed it to a fatal extreme. The Democratic National Convention adopted (August 29, 1864) a resolution (drafted by Vallandigham) declaring the war a failure, and demanding a cessation of hostilities; it named M'Clellan for the presidency and adjourning sine die as usual, remained organized, and subject to be convened at any time and place by the executive national committee. This threatening attitude, in conjunction with alarming indications of a conspiracy to resist the draft, had the effect to thoroughly consolidate the war party, which had on the 8th of June unanimously renominated Lincoln, and had nominated Andrew Johnson of Tennessee for the vice-presidency. At the election held on the 8th of November 1864, Lincoln received 2,216,076 of the popular votes, and M'Clellan (who had openly disapproved of the resolution declaring the war a failure) but 1,888,725; while of the presidential electors 212 voted for Lincoln and 21 for M'Clellan. Lincoln's second term of office began March 4, 1865.

While this political contest was going on the Civil War was being brought to a decisive close. Grant, at the head of the Army of the Potomac, followed Lee to Richmond and Petersburg, and held him in siege to within a few days of final surrender. General W. T. Sherman, commanding the bulk of the Union forces in the Mississippi Valley, swept in a victorious march through the heart of the Confederacy to Savannah on the coast, and thence northward to North Carolina. Lee evacuated Richmond on the 2nd of April, and was overtaken by Grant and compelled to surrender his entire army on the 9th of April 1865. Sherman pushed Johnston to a surrender on the 26th of April. This ended the war.

Lincoln being at the time on a visit to the army, entered Richmond a few days after its surrender. Returning to Washington, he made his last public address on the evening of the 11th of April, devoted mainly to the question of reconstructing loyal govern-
LINCOLN

Lincoln, a city and county of a city, municipal, county and parliamentary borough, and the county town of Lincolnshire, England. Pop. (1901) 48,784. It is picturesquely situated on the summit and south slope of the limestone ridge of the Clifft range of hills, which rises from the north bank of the river Witham, at its confluence with the Foss Dyke, at an altitude of 200 ft. above the river. The cathedral rises majestically from the crest of the hill, and is a landmark for miles. The distance of the city from London is 130 m. by W. from London by the Great Northern railway; it is also served by branches of the Great Eastern, Great Central and Midland railways.

Lincoln is one of the most interesting cities in England. The ancient British town occupied the crown of the hill beyond the Newport or North Gate. The Roman town consisted of two parallelograms of unequal length, the first extending west from the Newport gate to a point a little west of the castle keep. The second parallelogram, added as the town increased in size and importance, extended due south from this point down the hill towards the Witham as far as Newland, and thence in a direction due east as far as Broad Street. Returning thence due north, it joined the south-east corner of the first and oldest parallelogram in what was afterwards known as the Minster yard, and terminated its east side upon its junction with the north wall in a line with the Newport gate. This is the oldest part of the town, and is named "above hill." After the departure of the Romans, the city walls were extended still farther in a south direction across the Witham as far as the great bar gate, the south entrance to the High Street of the city; the junction of these walls with the later Roman one was effected immediately behind Broad Street. The "above hill" portion of the city consists of narrow irregular streets, some of which are too steep to admit of being ascended on foot. The south portion, which is named " below hill," is much more commodious, and contains the principal business premises. Here also are the railway stations.

The glory of Lincoln is the noble cathedral of the Blessed Virgin Mary, commonly known as the Minster. As a study to the architect and antiquary this stands unrivalled, not only as regards the earlier part, but as containing within its compass every variety of style from the simple massive Norman of the central west front, and the later and more ornate examples of that style in the west doorways and towers; onward through all the Gothic styles, of each of which both early and late examples appear. The building material is the oolite and calcareous stone of Lincoln Heath and Haydon, which has the peculiarity of becoming hardend on the surface when tumbled. Formerly the cathedral had three spires, all of wood or leaded timber. The spire on the central tower, which would appear to have been the highest in the world, was blown down in 1547. Those on the two western towers were removed in 1808.

The ground plan of the first church, adopted from that of Rouen, was laid by Bishop Remigius in 1086, and the church was consecrated three days after its death, on the 6th of May 1092. The west front is flanked by two of an Early English screen (c. 1225) thrown over the Norman front, the west towers rising behind it. The earliest Norman work is part of that of Remigius; the great portals and the west towers up to the third storey are Norman c. 1148. The upper parts of the western towers are of 1215-25, the spires are of 1422-45 and 1446-50 respectively. The nave and aisles were completed c. 1220. The transept, mainly built between 1186 and 1235 have two fine rose windows, that in the N. is Early English, and that in the S. Decorated. The first choir contained a group of stalls, stained 1826-33; the choir is respectively the Dean's Eye and Bishop's Eye. A Galilee of rich Early English work forms the entrance of the S. transept. Of the choir the western portion known as Sir Hugh's (1186-1204) is the famous first example of pointed work; the eastern, called the Angel Choir, is a magnificently ornate work completed in 1280. Fine Perpendicular canopied stalls fill the western part. The great east window, 57 ft. in height, is an example of transition from Early English to Decorated. The nave windows are Decorated, the tracery in the interior are the Easter sepulchre (c. 1300), the foliage ornamentation of which is beautifully natural; and the organ screen of a somewhat earlier date. The great central tower is Early English as far as the base; the two lower stages of the structure of the higher part is an addition of 1371-80. The height is 271 ft.; and the tower contains the bell, Great Tom of Lincoln, weighing over 5 tons. The dimensions of the cathedral internally are—nave, 425 × 79-6 × 80 ft.; choir, 158 × 80 × 72 ft.; angel choir, which includes presbytery and lady chapel, 168 × 44 × 72 ft.; main transept, 220 × 63 × 74 ft.; choir transept, 166 × 44 × 72 ft. The west towers are 206 ft. high. The buildings of the close that call for notice are the chapterhouse of ten bays, 60 ft. diameter, 42 ft. high, with a fine vestibule of the same height, built c. 1225, and therefore the earliest of English polygonal chapter-houses, and the library, a building of 1675, which contains a small museum. The picturesque episcopal palace contains the bishop's rooms, the bishop's chapel and the diocesan records. The great cloister of 1370-80 is 135 ft. square. There is an elaborate basement, with a tower at each corner and a central tower, with spire. The great east tower is the most notable example of English Early English. There is a Gallery which contains the richest English work, and much Perpendicular, including the gateway. It fell into disuse after the Reformation, but by extensive restoration was brought back to its proper use at the end of the 19th century. Among the most famous bishops were St Hugh of Avalon (1180-1200); Robert Grosseteste (1235-1253); Richard Fleming (1420-1431), founder of Lincoln College, Oxford; William Smith (1495-1514), founder of Brasenose College, Oxford; William Warham (1509-1572) and John Henning (1766-1723). Every stall has produced a prelate or cardinal. The see covers almost the whole of the county, with very small portions of Norfolk and Yorkshire, and it included Nottinghamshire until the time of the bishopric of Southwell in 1884. At its earliest formation, when Remigius, almoner of the abbey of Fécamp, removed the seat of the bishopric here from Rochester in Oxfordshire shortly after the Conquest, it extended from the Humber to the Thames, eastward beyond Cambridge, and westward beyond Leicester. It was reduced, however, by the formation of the sees of Ely, Peterborough and Oxford, and by the rearrangement of diocesan boundaries in 1837.
LINCOLN

The remains of Roman Lincoln are of the highest interest. The Newport Arch or northern gate of Lindum is one of the most perfect specimens of Roman architecture in England. It consists of a great arch flanked by two smaller arches, of which one remains. The Roman Ermine Street runs through it, leading northward almost in a straight line to the Humber. Fragments of the town wall remain at various points; a large quantity of coins and other relics have been discovered; and remains of a burial-place and buildings unearthed. Of these last the most important is the series of column-bases, probably belonging to a Basilica, beneath a house in the street called Ball Gate, adjacent to the Newport Arch. A villa in Greetwell; a tesselated pavement, a milestone and other relics in the cloister; an altar unearthed at the church of St Swithin, are among many other discoveries. Among churches, apart from the minster, two of outstanding interest are those of St Mary-le-Wigford and St Peter-at-Gows (i.e. slice-gates), both in the lower part of High Street. Their towers, closely similar, are fine examples of perhaps very early Norman work, though they actually possess the characteristics of pre-Conquest workmanship. Braccebridge church shows similar early work; but as a whole the churches of Lincoln show plainly the results of the siege of 1064, and such buildings as St Botolph's, St Petter's-at-Arches and St Martin's are of the period 1720-1740. Several churches are modern buildings on ancient sites. There were formerly three small priories, five friaries and four hospitals in or near Lincoln. The preponderance of friaries over priories of monks is explained by the fact that the cathedral was served by secular canons. Bishop Grosseteste was the devoted patron of the friars, particularly the Franciscans, who were always in their day the town missionaries. The Greyfriars, near St Swithin's church, is a picturesque and storied building of the 13th century. Lincoln is rich in early domestic architecture. The building known as John of Gaunt's stables, actually St Mary's Guild Hall, is of tw storeys, with rich Norman doorway and moulding. The Jews' house is another fine example of 12th-century building; and Norman remains appear in several other houses, such as Deloraine Court and the House of Aaron the Jew. Lincoln Castle, lying W. of the cathedral, was newly founded by William the Conqueror when Remigius decided to found his minster under its protection. The site, with its artificial mounds, is of much earlier, probably British, date. There are Norman remains in the Gateway Tower; parts of the walls are of this period, and the keep dates from the middle of the 12th century. Among medieval gateways, the Exchequer Gate, serving as the finance-office of the chapter, is of fine specious of 13th-century work. Parliament Gate is of the 14th century, and Station House in High Street of the 15th, with the Guildhall above it. St Dunstan's Lock is the name, corrupted from Duncastle, now applied to the entrance to the street where a Jewish quarter was situated; here lived the Christian boy afterwards known as "little St Hugh," who was asserted to have been crucified by the Jews in 1255. His shrine remains in the S. choir aisle of the minster. Other antiquities are the Perpendicular conduit of St Mary in High Street and the High Bridge, carrying High Street over the Witham, which is almost unique in England as retaining some of the old houses upon it.

Among modern public buildings are the county hall, old and new corn exchanges and public library. Educational establishments include a grammar school, a girls' high school, a science and art school and a theological college. The arboretum in Monks Road is the principal pleasure-ground; and there is a race-course. The principal industry is the manufacture of agricultural machinery and implements; there are also iron foundries and maltings, and a large trade in corn and agricultural produce. The parliamentary borough, returning one member, falls between the Gainsborough division of the county on the N., and that of Sleaford on the S. Area, 3755 acres.

History.—The British Lindun, which, according to the geography of Claudius Ptolemaeus, was the chief town of the Coritani, was probably the nucleus of the Roman town of Lindum. This was at first a Roman legionary fortress, and on the removal of the troops northward was converted into a municipality with the title of colonia. Such important structural remains as have been described attest the rank and importance of the place, which, however, did not attain a very great size. Its bishop attended the council of Arles in 314, and Lincoln (Lindocolina, Lincolle, Nicole) is mentioned in the Itinerary of Antoninus written about 320. Although said to have been captured by Hengest in 475 and recovered by Ambrosius in the following year, the next authentic mention of the city is Bede's record that Paulinus preached in Lindsey in 628 and built a stone church at Lincoln in which he consecrated Honorius bishop of Canterbury. During their inroads into Mercia, the Danes in 877 established themselves at Lincoln, which was one of the five boroughs recovered by King Edmund in 941. A mint established here in the reign of Alfred was maintained until the reign of Edward I. (Mint Street turning from High Street near the Stonebow recalls its existence.) At the time of the Domesday Survey Lincoln was governed by twelve Lawmen, relics of Danish rule, each with hereditable franchises of sac and soc. Whereas it had rendered £50 annually to King Edward, and £10 to the earl, it then rendered £100. There had been 1150 houses, but 240 had been destroyed since the time of King Edward. Of these 156 had suffered by the raising of the castle by William I. in 1068 partly on the site of the Roman camp. The strength of the position of the castle brought much fighting on Lincoln. In 1141 King Stephen regained both castle and city from the empress Maud, but was attacked and captured in the same year at the "Joust or Lincoln." In 1144 he besieged the castle, held by the earl of Chester, and recovered it as a pledge in 1146. In 1191 it was held by Gerard de Camville for Prince John and was besieged by William Longchamp, Richard's chancellor, in 1210 it stood a siege by the partisans of the French prince Louis, who were defeated at the battle called Lincoln Fair on the 19th of May 1217. Granted by Henry III. to William Longepée, earl of Salisbury, in 1224, the castle descended by the marriage of his descendant Alice to Thomas Plantagenet, and became part of the duchy of Lancaster.

In 1157 Henry II. gave the citizens their first charter, granting them the city at a fee-farm rent and all the liberties which they had had under William II., with their gild merchant for themselves and the men of the county as they had then. In 1200 the citizens obtained release from all but pleas of the Crown without the walls, and pleas of external tenure, and were given the pleas of the Crown within the city according to the customs of the city of London, on which those of Lincoln were modelled. The charter also gave them quittance of toll and customs throughout the kingdom, and of certain other dues. In 1230 the citizens owed the exchequer £100 for the privilege of having a mayor, but the office was abolished by Henry III. and by Edward I. in 1290, though restored by the charter of 1300. In 1275 the citizens claimed the return of writs, assize of bread and ale and other royal rights, and in 1301 Edward I., when confirming the previous charters, gave them quittance of murage, pannage, portage and other dues. The mayor and citizens were given criminal jurisdiction in 1327, when the loughmanmot held weekly in the gildhall since 1272 by the mayor and bailiffs was ordered to hear all local pleas which led to friction with the judges of assize. The city became a separate county by charter of 1409, when it was decreed that the bailiffs should henceforth be sheriffs and the mayor the king's escheator, and the mayor and sheriffs with four others justices of the peace with defined jurisdiction. As the result of numerous complaints of inability to pay the fee-farm rent of £180 Edward IV. enlarged the bounds of the city in 1466, while Henry VIII. in 1546 gave the citizens four advowsons, and possibly also in consequence of declining trade the city market was made free of tolls in 1554. Incorporated by Charles I. in 1628 under a common council with 13 aldermen, 4 coroners and other officers, Lincoln surrendered its charters in 1684, but the first charter was restored after the Revolution, and was in force till 1834.

Parliaments were held at Lincoln in 1301, 1316 and 1327, and the city returned two burgesses from 1295 to 1885, when it lost one member. After the 13th century the chief interests
of Lincoln were ecclesiastical and commercial. As early as 1103 Odericus declared that a rich citizen of Lincoln kept the treasure of King Magnus of Norway, supplying him with all he required, and there is other evidence of intercourse with Scandinavia. There was an important Jewish colony, Aaron of Lincoln being one of the most influential financiers in the kingdom between 1165 and 1186. It was probably jealousy of their wealth that brought the charge of the crucifixion of “little St Hugh” in 1255 upon the Jewish community. Made a staple of wool, leather and skins in 1291, famous for its scarlet cloth in the 13th century, Lincoln had a few years of great prosperity, but with the transference of the staple to Boston early in the reign of Edward III., its trade began to decrease. The craft gilds remained important until after the Reformation, a pageant still being held in 1566. The fair now held during the last whole week of April would seem to be identical with that granted by Charles II. in 1684. Edward III. authorized a fair from St Botolph's day to the feast of SS Peter and Paul in 1327, and William III. gave one for the first Wednesday in September in 1696, while the present November fair is, perhaps, a survival of the one granted in 1329 for fifteen days before the feast of the Deposition of St Hugh.

The Lincoln judgment attracted the first permanent settlers to the site of Lincoln in 1836, and settlers and freemen came long distances to reduce the brine or to scrape up the dry-weather surface deposits. In 1886–1887 the state sank a test-well 2463 ft. deep, which discredited any hope of a great underground flow or deposit. Scarcely any use is made of the salt waters locally. Lancaster county was organized extra-legally in 1830, and under legislative act in 1864; Lancaster village was platted and became the county-seat in 1864 (never being incorporated); and in 1867, when it contained five or six houses, its site was selected for the state capital after a hard-fought struggle between different sections of the state (see Nebraska). The new city was incorporated as Lincoln (and formally declared the county-seat by the legislature) in 1865, and was chartered for the first time as a city of the second class in 1871; since then its charter has been repeatedly altered. After 1887 it was a city of the first class, and after 1890 the only member of the highest subdivision in that class. After a “reform” political campaign, the chartering in 1887 of a town council by the mayor and city council, in defiance of an injunction of a federal court, led to a decision of the U.S. Supreme Court, favourable to the city authorities and important in questions of American municipal government.

LINCOLN—LINCOLN JUDGMENT. The in this celebrated English ecclesiastical suit, the bishop of Lincoln (Edward King, q.v.) was cited before his metropolitan, the archbishop of Canterbury (Dr Benson), to answer charges of various ritual offences committed at the administration of Holy Communion in the church of St Peter at Gowts, in the diocese of Lincoln, on the 4th of December, 1887, and in Lincoln cathedral on the 10th of December, 1887. The promoters were Ernest de Lacy Read, William Brown, Felix Thomas Wilson and John Marshall, all inhabitants of the diocese of Lincoln, and the last two parishioners of St Peter at Gowts. The case has a permanent importance in two respects. First, certain disputed questions of ritual were legally decided. Secondly, the jurisdiction of the archbishop of Canterbury alone to try one of his suffragan bishops for alleged ecclesiastical offences was considered and judicially declared to be well founded both by the judicial committee of privy council and by the archbishop of Canterbury with the concurrence of his assessors. The proceedings were begun on the 2nd of June 1888 by a petition presented by the promoters to the archbishop, praying that a citation to the bishop of Lincoln might issue calling on him to answer certain ritual charges. On the 26th of June 1888 the archbishop, by letter, declined to issue citation, on the ground that it would be an infringement of his jurisdiction, as he was not clear that he had it. The promoters appealed to the judicial committee of privy council, to which an appeal lies under 25 Henry VIII. c. 19 for “lack of justice” in the archbishop’s court. The matter was heard on the 20th of July 1888, and on the 8th of August 1888 the committee decided (1.) that an appeal lay from the refusal of the archbishop to the judicial committee, and (ii.) that the judicial committee had jurisdiction to issue a citation to the bishop of Lincoln and to hear the promoters’ complaint, but they abstained from expressing an opinion as to whether the archbishop had a discretion to refuse citation—whether, in fact, he had any power of “veto” over the prosecution. The case being thus remitted to the archbishop, he decided to entertain it, and on the 4th of January 1889 issued a citation to the bishop of Lincoln. On the 12th of February 1889 the archbishop of Canterbury sat in Lambeth Palace Library, accompanied by the bishops of London (Dr Temple), Winchester (Dr Harold Brown), Oxford (Dr Stubbs) and Salisbury (Dr Wordsworth), and the vicar-general (Sir J. Parker Deane) as assessors. The bishop of Lincoln appeared in person and read a “Protest” to the archbishop’s jurisdiction to try him except in a court composed of the archbishop and all the bishops of the province as judges. The court adjourned in order that the question of jurisdiction might be argued. On the 11th of May the archbishop gave judgment to

1 Lincoln was about equally distant from Pawnee City and the Kansas border, the leading Missouri river towns, and the important towns of Fremont and Columbus on the N. side of the Platte.
the effect that whether sitting alone or with assessors he had jurisdiction to entertain the charge. On the 23rd and 24th of July 1895 a further preliminary objection raised by the bishop of Lincoln's counsel was argued. The offences alleged against the bishop of Lincoln were largely breaches of various rubrics in the communion service of the Prayer Book which give directions to the "minister." These rubrics are by the Acts of Uniformity (1 Elizabeth c. 2, and 13 & 14 Car. II. c. 4) made legally binding. But it was argued that a bishop is not a "minister" so as to be bound by the rubrics. The archbishop, however, held otherwise, and the assessors (except the bishop of Salisbury, who dissented) concurred in this decision. At this and subsequent hearings the bishop of Hereford (Dr Atlay) took the place of the bishop of Winchester as an assessor, and the bishop of Rochester (Dr Thorold), originally appointed an assessor, but absent from England at the outset, was present.

The case was heard on its merits in February 1890, before the archbishop and all the assessors, and the archbishop delivered his judgment on the 21st of November 1890. The alleged offences were eight in number. No facts were charged with having mixed water with wine in the chalice during the communion service, and II. with having administered the chalice so mixed to the communicants. It was decided that the mixing of the water with the wine during service was illegal, because an additional ceremony not enjoined in the Prayer Book, but that the administration of the mixed chalice, the mixing having been effected before service, was in accordance with primitive practice and not forbidden in the Church of England. III. The bishop was charged with the ceremonial washing of the vessels used for the holy communion, and with drinking the water used for these ablutions. It was decided that the bishop had committed no offence, and that what he had done was a reasonable compliance with the requirement of the rubric that any of the consecrated elements left over at the end of the celebration should be then and there consumed. IV. The bishop was charged with taking the eastward position (i.e. standing at the west side of the holy table with his face to the east and his back to the congregation) during the ante-communion service (i.e. the part of the communion service prior to the consecration prayer). The rubric requires the celebrant to stand at the north side of the table. A vast amount of research convinced the archbishop that "Manual Acts" could actually and by right be done with equal accuracy be applied to the north end of the table as now arranged in churches, and to the long side of the table, which, in Edward VI.'s reign, was often placed lengthwise down the church, so that the long sides would face north and south. It was therefore decided (one of the assessors dissenting) that both positions are legal, and that the bishop had not offended in adopting the eastward position. V. The bishop was charged with standing during the consecration prayer that the "Manual Acts" of consecration were done in the people gathered round. It should be stated that the courts (see Ridsdale v. Clifton, L.R. 1 P.D. 316; 2 P.D. 276) had already decided that the eastward position during the consecration prayer was legal, but that it must not be so used by the celebrant as to conceal the "Manual Acts" and also that so used it was an act of "obtuse folly". The bishop had transgressed the law in this particular. VI. The bishop was charged with having, during the celebration of holy communion, allowed two candles to be alight on a shelf or retable behind the altar when they were not necessary for giving light. The archbishop decided that the mere presence of two altar candles burning during the service, but lit before it began, was lawful under the First Prayer Book of Edward VI., and has never been made unlawful, and, therefore, that the bishop was justified in what he had done. VII. The bishop was charged with having permitted the hymn known as Agnus Dei to be sung immediately after the consecration of the elements at a celebration of the holy communion. The archbishop decided that the use of this particular hymn at this point of the service from the use of other hymns on other occasions in public worship.

VIII. The bishop was charged with making the sign of the Cross in the air with his hand in the benediction and at other times during divine service. The archbishop held that these crossings were ceremonies not enjoined and, therefore, illegal. The judgment confined itself to the legal declarations here summarized, and pronounced no monition or other sentence on the bishop of Lincoln in respect of the matters in which he appeared to have committed breaches of the ecclesiastical law.

The promoters appealed to the judicial committee. The bishop did not appear on the appeal, which was therefore argued on the side of the promoters only. The appeal was heard in June and July 1897, before Lords Halsbury, Hobhouse, Ether, Herschell, and the assessor. On the 2nd of August 1897 the appeal failed on all points. As to II., III., IV., and VII. the Committee agreed with the archbishop. As to VI. (altar lights) they held that, as it was not shown that the bishop was responsible for the presence of lighted candles, the charge could not be sustained against him, and so dismissed it without considering the general question of the lawfulness of altar lights. They also held that the archbishop was within his right in pronouncing no sentence against the bishop, who, it should be added, confirmed his practice to the judgment from the date of its delivery.

**LINCOLNSHIRE**, an eastern county of England, bounded N. by the Humber, E. by the German Ocean and the Wash, S.E. for 3 m. by Norfolk, S. by Cambridgeshire and Northamptonshire, S.W. by Rutland, W. by Leicestershire and Nottinghamshire, and N.W. by Yorkshire. The area is 2646 sq. m., the county being second to Yorkshire of the English counties in size.

The coast-line, about 110 m. in length, including the Humber shore, is generally low and marshy, and artificial banks for guarding against the inroads of the sea are to be found, in places, all along the coast. From Grimsby to Skegness traces of a submarine forest are visible; but while the sea is encroaching upon some parts of the coast it is receding from others, as shown by Holbeach, which is now 6 m. from the sea. Several thousand acres have been reclaimed from this part of the Wash, and round the mouth of the Nene on the south-east. The deep bay between the coasts of Lincolnshire and Norfolk, called the Wash, is full of dangerous sandbanks and silt; the navigable portion off the Lincolnshire coast is known as the Boston Deepes. The rapidity of the tides in this inlet, and the lowness of its shores, which are generally indistinct on account of mist from a moderate offing, render this the most difficult portion of the navigation of the east coast of England. On some parts of the coast there are fine stretches of sand, and Cleethorpes, Skegness, Mablethorpe and Sutton-on-Sea are favourite resorts for visitors.

The surface of Lincolnshire is generally a large plain, small portions of which are slightly below the level of the sea. The south-east parts are perfectly flat; and about one-third of the county consists of level, sandy marshes, intersected in all directions by artificial drains, called locally dykes, delphys, drains, becks, leams and eaux. This flat surface is broken by two ranges of calcareous hills running north and south through the county, and known as the Lincoln Edge or Heights, or the Cliff, and the Wolds. The former range, on the west, runs nearly due north from Grantham to Lincoln, and thence to the Humber, traversing the Heaths of Lincolnshire, which were formerly open moors, rabbit Warrens and sheep walks, but are now enclosed and brought into high cultivation. The Wolds form a ridge of bold hills extending from Spilsby to Barton-on-Humber for about 40 m., with an average breadth of about 8 m. The Humber separates Lincolnshire from Yorkshire. Its ports on the Lincolnshire side are the small ferry-ports of Barton and New Holland, and the important harbour of Grimsby. The Trent forms part...
of the boundary with Nottinghamshire, divides the Isle of Axholme (q.v.) from the district of Lindsey, and falls into the Humber about 30 m. below Gainsborough. The Witham rises on the S.W. border of the county, flows north past Grantham to Lincoln, and thence E. and S.E. to Boston, after a course of about 80 m. The Welland rises in north-west Northamptonshire, enters the county at Stamford, and, after receiving the Glen, flows through an artificial channel into the Fosdyke Wash. The Nene on the south-east has but a small portion of its course in Lincolnshire; it flows due north through an artificial outfall, called the Wisbech Cut. Between the Witham and the sea lies the Marshes, a level tract of rich alluvial soil extending from Barton-on-Humber to Wainflect, varying in breadth from 5 to 10 m. Between the Welland and the Nene in the south-east of the county are the Gedney Marsh, Holbeach Marsh, Moulton Marsh and Sutton Marsh.

The Fens (q.v.), the soil of which has been formed partly by tidal action and partly by the decay of forests, occupy the Isle of Axholme on the north-west, the vale of Anholme on the north, and most of the county south-east of Lincolnshire. The chief of these are the Holland, Wildmere, West and East Fens draining into the Witham; and the Deeping, Bourn, Great Porsand, and Whaplode Fens draining into the Welland.

The low lands adjoining the tidal reaches of the Trent and Humber, and part of those around the Wash have been raised above the natural level and enriched by the process of warping, which consists in letting the tide run over the land, and retaining it there a sufficient time to permit the deposit of the sand and mud held in solution by the waters.

**Geology.**—The geological formations for the most part extend in parallel belts, nearly in the line of the length of the country, from north to south, and succeed one another in ascending order from east to west. The lowest is the Triassic Keuper found in the Isle of Axholme and Anholme and a fragment of the Shale, and has been discovered at the battle of Kesteven. The series of these is the Holland, Wildmere, West and East Fens, and the Deeping, Bourn, Great Porsand, and Whaplode Fens.

The Fens are occupied by long narrow tracts of the most fertile soil, and are remarkable for the richness of their natural vegetation. The great variety of the fen plants are partly due to the great variety of the substrata, and partly to the nature of the fen water. Each fen is thus a distinct habitat for plants, and the fens of one district cannot be interchanged with those of another. The fens of the S. are the most fertile, and those of the N. the least; and the fens of the W. are the most fertile, and those of the E. the least. The fens of the S. are the most fertile, and those of the N. the least; and the fens of the W. are the most fertile, and those of the E. the least. The fens of the S. are the most fertile, and those of the N. the least; and the fens of the W. are the most fertile, and those of the E. the least. The fens of the S. are the most fertile, and those of the N. the least; and the fens of the W. are the most fertile, and those of the E. the least. The fens of the S. are the most fertile, and those of the N. the least; and the fens of the W. are the most fertile, and those of the E. the least. The fens of the S. are the most fertile, and those of the N. the least; and the fens of the W. are the most fertile, and those of the E. the least.
and of castle, into in commission to was acknowledged ravaged the about districts among which quarter Lindsey Districts—.

2. Parts of Kesteven. Municipal boroughs—Grantham (17, 761), Urban districts—Bourne (4361), Braceybridge (17, 523), Ruskinbridge (11, 1065), Sleights (5, 665). 3. Parts of Holland. Municipal borough—Boston (15, 667). Urban districts—Holbeach (4, 755), Long Sutton (25, 742), Spalding (9, 384), Sutton Bridge (2, 705). In the Parts of Holland the borough of Boston has a separate commission of the peace and there are two petty sessions divisions. Lincolnshire is in the Midland circuit.

In the Parts of Kesteven the boroughs of Grantham and Stamford have each a separate commission of the peace and separate courts of quarter sessions. There are also two petty sessions divisions in the Parts of Lindsey the county borough of Grimsby and Lincoln have each a separate commission of the peace and a separate court of quarter sessions, while the municipal borough of Louth has a separate commission of the peace, and there are petty sessions divisions. The three administrative counties and the county borough of Lincoln contain together 761 civil parishes. The ancient county contains 580 ecclesiastical parishes and districts, wholly or in part. It is mostly in the diocese of Lincoln, but in part also in the dioceses of Southwell and York. For parliamentary purposes the county is divided into seven divisions, namely, West Lindsey or Gainsborough, North Lindsey or Brigg, East Lindsey or Louth, South Lindsey or Horncastle, South Kesteven or Stamford, and Holland or Spalding, and the parliamentary boroughs of Boston, Grantham, Grimsby and Lincoln, each returning one member.

History. Of the details of the English conquest of the district which is now Lincolnshire little is known, but at some time in the 6th century Engle and Frisian invaders appear to have settled in the country north of the Witham, where they became known as the Linds懷ars, the southern districts from Boston to the Trent basin being at this time dense woodland. In the 7th century the supremacy over Lindsey alternated between Mercia and Northumbria, but few historical references to the district are extant until the time of Alfred, whose marriage with Ealswith was celebrated at Gainsborough three years before his accession. At this period the Danish invasions upon the coast of Lindsey had already begun, and in 873 Healfdene wintered at Torksey, while in 878 Lincoln and Stamford were included among the five Danish boroughs, and the organization of the districts dependent upon them probably resulted about this time in the grouping of Lindsey, Kesteven and Holland to form the shire of Lincoln. The extent and permanence of the Danish influence in Lincolnshire is still observable in the names of its towns and villages and in the local dialect, and, though about 928 the confederate boroughs were recaptured by Edward the Elder, in 961 a Viking fleet again entered the Humber and ravaged Lindsey, and in 1013 the district of the five boroughs acknowledged the supremacy of Sweyn. The county offered no army at the instance to the Conqueror, and though Hereward appears in the Domesday Survey it was dispossessed under-tenant of the abbot of Peterborough at Witham-on-the-Hill, the legends surrounding his name do not belong to this county. In 1068 the Conqueror built a castle at Lincoln, and portioned out the principal estates among his Norman followers, but the Domesday Survey shows that the county on the whole was leniently treated, and a considerable number of Englishmen retained their lands as subtenants.

The origin of the three main divisions of Lincolnshire is anterior to that of the county itself, and the outcome of purely natural conditions, Lindsey being in Roman times practically an island bounded by the swamps of the Trent and the Witham on the west and south and on the east by the North Sea, while Kesteven and Holland were respectively the regions of forest and of fen. Lindsey in Norman times was divided into three ridings—North, West and South—comprising respectively five, five and seven wapentakes; while apart from their division into wapentakes, the Domesday Survey exhibits a unique planning out of the ridings into approximately equal numbers of 12-carcature hundreds, the term hundred possessing here no administrative or local significance, but serving merely as a unit for area of purposes of assessment. The Norman division of Holland into the three wapentakes of Elloe, Kirton and Skirbeck has remained unchanged to the present day. In Kesteven the wapentakes of Aswardthurn, Aveland, Beltisloe, Hazwell, Langoe, Loveden, Ness, Winnibriggs, and Grantham Soke have been practically maintained, but the Domesday wapentake of Boothby and Graffe now forms the wapentake of Boothby Graffe. In Northriding Bradley and Haverstoe have been combined to form Bradley Haverstoe wapentake, and the Domesday wapentake of Epworth in Westriding has been absorbed in that of Mansfield. Wall wapentake in Westriding was a liberty of the bishop of Lincoln, and as late as 1515 the dean and chapter of Lincoln claimed delivery and return of rents in the manor and hundred of Navenby. In the 13th century Baldwin Wake claimed return of rents and a market in Aveland. William de Vesci claimed liberties and exemptions in Caythorpe, of which he was summoned to render account at the sheriff's court at Halton. The abbots of Peterborough, the abbot of Topholme, the abbots of Bardney, the prior of Cleving, the prior of Sixhills, the abbot of St Mary's, York, the priores of Stewold and several lay owners claimed liberties and jurisdiction in their Lincolnshire estates in the 13th century.

The county court for Lincolnshire was held at Lincoln every forty days, the lords of the manor attending with their stewards, or in their absence the reeve and four men of the vill. The riding were each presided over by a riding sheriff and wapentake courts were held in the reign of Henry I. twelve times a year, and in the reign of Henry III. every three weeks, while twice a year the freemen of the wapentake were summoned to the view of frankpledge or tourn held by the sheriff. The boundaries between Kesteven and Holland were a matter of dispute as early as 1389 and were not finally settled until 1816.

Lincolnshire was originally included in the Mercian diocese of Lichfield, but, on the subdivision of the latter by Theodore in 680, the ten-district was included in the diocese of Lichfield, while the sec for the northern parts of the county was placed at "Sidnacester," generally identified with Stow. Subsequently both dioceses were merged in the vast West-Saxon bishopric of Dorchester, the see of which was afterwards transferred to Winchester, and by Bishop Remigius in 1072 to Lincoln. The archdeaconry of Lincoln was among those instituted by Remigius, and the division into rural deaneries also dates from this period. Stow archdeaconry is first mentioned in 1135, and in 1291 included four deaneries, while the archdeaconry of Lincoln included twenty-three. In 1536 the additional deaneries of Hill, Holland, Loveden and Graffoe had been formed within the archdeaconry of Lincoln, and the only deaneries created since that date are East and West Elloe and North and South Grantham in Lincoln archdeaconry. The deaneries of Cartree, Grimsby, Hill, Horncastle, Louthesh, Ludborough, Walshcroft, Wragge and Yarborough have been transferred from the archdeaconry of Lincoln to that of Stow. Benedictine foundations existed at Icknham, Barrow, Bardney, Partney and Crowland as early as the 7th century, but all were destroyed in the Danish wars, and only Bardney and Crowland were ever rebuilt. The revival of monasticism after the Conquest resulted in the erection of ten Benedictine monasteries, and a Benedictine nunnery at Stainfield. The Cistercian abbey of Kirtston, Louth Park, Revesby, Vaudley and Swineshead, and the Cistercian nunnery at Stich would have been in the reign of Stephen, and at the time of the Dissolution there were upwards of a hundred religious houses in the county.

In the struggles of the reign of Stephen, castles at Newark and Sleaford were raised by Alexander, bishop of Lincoln, against the king, while Ranulf "Gernons," earl of Chester, in 1140 garrisoned Lincoln for the empress. The seizure of Lincoln by Stephen in 1141 was accompanied with fearful butchery and devastation, and by an assent at Stamford William of Roumare received Kirton in Lindsey, and his tenure of Gainsborough Castle was confirmed. In the baronial outbreak of 1173 Roger Mowbray, who had inherited the Isle of Axholme from Nigel d'Albini, garrisoned Ferry East, or Kinnard's Ferry, and Axholme against the king; and, after the destruction of their more northern fortresses in this campaign, Epworth in Axholme became the
LINCOLNSHIRE

principal seat of the Mowbrays. In the struggles between John and his barons Lincoln in 1216 made peace with the king by surrendering hostages for the payment of a fine of 1000 marks, but after the landing of Louis the city was captured by Gilbert de Gant, then earl of Lincoln. After his disastrous march to Swineshead Abbey, John journeyed through Seaford to Newark, where he died, and in the battle of Lincoln in 1217 Gilbert de Gant was captured and the city sacked. At the time of the Wars of the Roses the county, owing to territorial influence, was mainly Lancastrian, and in 1461 the Yorkist strongholds of Grantham and Stamford were sacked to such effect that the latter never recovered. The Lincolnshire rising of 1470 was crushed by the defeat of the rebels in the skirmish known as "Losecoat Field" near Stamford. In the Civil War of the 17th century, Lindsey for the most part declared for the king, and the Royalist cause was warmly supported by the earl of Lindsey, Viscount Newark, Sir Peregrine Bertie and the families of Dymoke, Henage and Thorold. Lord Willoughby of Parham was a prominent Parliamentary leader, and the Isle of Axholme and the Puritan yeomanry of Holland declared for the parliament. In 1643 Cromwell won a small victory near Grantham, and the Royalist garrisons at Lynn and Lincoln surrendered to Manchester. In 1644, however, Newark, Gainsborough, Lincoln, Seaford and Crowland were all in Royalist hands, and Newark only surrendered in 1646. Among other historic families connected with Lincolnshire were the Wakes of Bourne and the D’Eyncourt, who flourished at Blankney from the Conquest to the reign of Henry II. Belvoir Castle was founded by the Tooms, from whom it passed by the Daubeny, then to the Barons Ros and later to the Manners, earls of Rutland. In the Lindsey Survey of 1115-1118 the name of Roger Marmion, ancestor of the Marmion family, who had inherited the fief of Robert Despenser, appears for the first time.

At the time of the Domesday Survey there were between 400 and 500 mills in Lincolnshire; 2111 fisheries producing large quantities of eels; 361 salt-works; and iron forges at Stow, St Mary and at Bytham. Lincoln and Stamford were flourishing centres of industry, and markets existed at Kirton-in-Lindsey, Louth, Old Bolingbroke, Spalding, Barton and Partney. The early manufactures of the county are all connected with the woollen trade, Lincoln being noted for its scarlet cloth in the 13th century, while an important export trade in the raw material sprung up at Boston. The disafforestation of Kesteven in 1230 brought large areas under cultivation, and the same period is marked by the growth of the maritime and fishing towns, especially Boston (which had a famous fish-market), Grimsby, Barton, Saltfleet, Wainfleet and Wrangle. The Lincolnshire towns suffered from the general decay of trade in the eastern counties which marked the 15th century, but agriculture was steadily improving, and with the gradual drainage of the fen districts culminating in the vast operations of the 17th century, over 300,000 acres in the county were brought under cultivation, including more than two-thirds of Holland. The fen-drainage resulted in the extinction of many local industries, such as the trade in goose-feathers and the export of wild fowl to the London markets, a 17th-century writer terming this county "the aviary of England, 3000 mallards with other birds having been caught sometimes in August at one draught." Other historic industries of Lincolnshire are the breeding of horses and dogs and rabbit-snares; the Witham was noted for its pike; and ironstone was worked in the south, now chiefly in the north and west.

As early as 1295 two knights were returned to parliament for the shire of Lincoln, and two burgesses each for Lincoln, Grimsby and Stamford. In the 14th century Lincoln and Stamford were several times the meeting-places of parliament or important councils, the most notable being the Lincoln Parliament of 1301, while at Stamford in 1309 a truce was concluded between the barons, Piers Gaveston and the king. Stamford discontinued representation for some 150 years after the reign of Edward II.; Grantham was disfranchised in 1463 and Boston in 1552. Under the act of 1832 the county was divided into a northern and southern division, returning each two members, and Great Grimsby lost one member. Under the act of 1868 the county returned six members in three divisions and Stamford lost one member. Under the act of 1885 the county returned seven members in five constituencies; Lincoln, Boston and Grantham lost one member each and Stamford was disestablished.

Antiquities.—At the time of the suppression of the monasteries in the reign of Henry VIII. there were upwards of one hundred religious houses; and among the Fens rose some of the finest abbots held by the Benedictines. The Gilbertines were a purely English order which took its rise in Lincolnshire, the canons following the Austin Rule. They lived in separate houses, but formed a community having a common church in which the sexes were divided by a longitudinal wall. These houses were at Alvingham, Catley, Holland Brigg, Louth, Osbournby, Swineshead and Alford. The monastery was erected by Edward I. to his wife, Newstead in Lindsey, Sempringham, the chief house of the order, founded by St Gilbert of Gaunt in 1139, of which the Norman nave of the church is in use, Stamford (a college for students) and two nunneries of the order at Haverholme, Nun Ormsby and Tunstall.

The following are a few of the most famous abbeys. Barlings (Premonstratensian), N.E. of Lincoln, was founded 1154, for fourteen canons. The tower, Decorated, with arcading pierced with pinnacles, is one of the best in the country. The Benedictine Mitred Abbey of Crowland (q.v.) was founded 716, and refounded in 948. Part of the church is still in use. Thornton Abbey (Black Canons) in the north near the Humber was founded in 1210. The present church is a fine example of Decorated transepts, and the two sides of the decagonal chapter-house (1282) and the beautiful west gate-house, Early Perpendicular (1332-1388), with an oriel window on the east. Kirkstead Abbey (Cistercian) was founded in 1139. Little remains beyond an Early English chapel of singular beauty.

In the Parts of Lindsey several churches present curious early features, particularly the well-known towers of St Peter, Barton-on-Humber, St Mary-le-Wigford and St Peter at Gowts, Lincoln, which are most remarkable. A church for a family of the Bridges) of Norman of various dates, Botfoss and St James, Grimsby, for Early English, Tattershall and Thedlethorpe for Perpendicular are fine examples of various styles.

The Parts of Louth and Spalding are some of the churches are built of excellent stone which abounds at Ancaster and near Seaford. The church of St Andrew, Heckington, is the best example of Decorated architecture in the county; it is famed for its Easter sepulchre and fine sedilia. The noble church of St Wulfran, Grantham, with one of the finest arches in England, is alsoDecorated; this style in fact is particularly well displayed in Kesteven, as in the churches of Caythorpe, Claypole, Navenby and Ewerby. At Stamford (q.v.) there are five churches of various styles.

The principally notable church is the church of St Botolph, Boston (q.v.), which is another noteworthy example of Norman work; for Early English work the churches of Kirton-in-Holland, Pinchbeck and Weston may be noticed; for Decorated those at Donington and Spalding; and for Perpendicular, Gedney, together with parts of Kirton church. Of the two-tower styles, however, by far the most splendid example is the famous church of St Botolph, Boston (q.v.), with its magnificent lantern-crowned tower or "stump."

There are few remains of medieval castles, although the sites of some have not been discovered. Tattershall (a fine Perpendicular building in brick) are the most noteworthy, and there are also fragments at Boston and Seaford. Country seats worthy of note (chiefly modern) are Aswarby Hall, Belton House, Brocklesby, Casewick, Denton Manor, Easton Hall, Epworth, Harmston Hall, Havelock Priory, Holton Hall, Pant Hall, Riby Grove, Somerby Hall, Syston Park and Uffington. The city of Lincoln is remarkably rich in remains of domestic architecture from the Norman period onward, and there are several interesting examples of the medieval "hall-house.

In this connexion the remarkable triangular bridge at Crowland of the 14th century (see BRIDGES) should be mentioned.

LIND, JENNY—LINDAU, PAUL

LIND, JENNY (1820—1887), the famous Swedish singer, was born at Stockholm on the 6th of October 1820, the daughter of a lace manufacturer. Mlle Lundberg, an opera-dancer, first discovered her musical gift, and induced the child's mother to have her educated for the stage; during the first seven years in which she was what was called an "actress pupil," she occasionally appeared on the stage, but in plays, not operas, until 1836, when she made a first attempt in an opera by A. F. Lindblad. She was regularly engaged at the opera-house in 1837. Her first great success was as Agathe, in Weber's Der Freischütz, in 1838, and by 1841, when she started for Paris, she had already become identified with nearly all the parts in which she afterwards became famous. But her celebrity in Sweden was due in great part to her histrionic ability, and there is comparatively little said about her wonderful vocal art, which was only attained after a year's hard study under Manuel Garcia, who had to remedy many faults that had caused exhaustion in the vocal organs. On the completion of her studies she sang before G. Meyerbeer, in private, in the Paris Opera-house, and two years afterwards was engaged by him for Berlin, to sing in his Feldlager in Schlesien (afterwards remodelled as L'Étoile du nord); but the part intended for her was taken by another singer, and her first appearance took place in Norma on the 15th of December 1844. She appeared also in Weber's Euryanthe and Bellini's La Sonnambula, and while she was at Berlin the English manager, Alfred Bunn, induced her to sign a contract (which she broke) to appear in London in the following season. In December 1845 she appeared at a Gewandhaus concert at Leipzig, and made the acquaintance of Mendelssohn, as well as ofJoachim and many other distinguished German musicians. In her second Berlin season she added the parts of Donna Anna (Mozart's Don Giovanni), Julia (Spontini's Vestalina) and Valentine (Meyerbeer's Les Huguenots) to her repertory. She sang in operas or concerts at Aix-la-Chapelle, Hanover, Hamburg, Vienna, Darmstadt and Munich during the next year, and took up two Donizetti rôles, those of Lucia and "la Figlia del Reggimento," in which she was afterwards famous. At last Lumley, the manager of Her Majesty's Theatre, succeeded in inducing Mlle Lind to visit England, in spite of her dread of the penalties threatened by Bunn on her breach of the contract with him, and she appeared on the 4th of May 1847 as Alice in Meyerbeer's Robert le Diable. Her début had been so much discussed that the furore she created was a foregone conclusion. Nevertheless it exceeded everything of the kind that had taken place in London or anywhere else; the sufferings and struggles of her well-dressed admirers, who had to stand for hours to get into the pit, have become historic. She sang in several of her favourite characters, and in that of Susanna in Mozart's Figaro, besides creating the part of Amalia in Verdi's I Masnadieri, written for England and performed on the 22nd of July. In the autumn she appeared in operas in Manchester and Liverpool, and in concerts at Brighton, Birmingham, Hull, Edinburgh, Glasgow, Perth, Norwich, Bristol, Hull, Exeter, and Exeter. At Norwich began her acquaintance with the bishop, Edward Stanley (1779–1849), who was said to have led to her final determination to give up the stage as a career. After four more appearances in Berlin, and a short visit to Stockholm, she appeared in London in the season of 1848, when she sang in Donizetti's L'Elixir d'amore and Bellini's I Puritani, in addition to her older parts. In the same year she organized a memorable performance of Elia, with the receipts of which the Mendelssohn scholarship was founded, and sang at a great number of charity and benefit concerts. At the beginning of the season of 1849 she intended to give up operatic singing, but a compromise was effected by which she was to sing the music of six operas, performed without action, at Her Majesty's Theatre; but the first, a concert performance of Mozart's II Flauto magico, was so coldly received that she felt bound, for the sake of the manager and the public, to give five more regular representations, and her last performance on the stage was on the 20th of May 1849, in Robert le Diable. Her decision was not even revoked when the king of Sweden urged her to reappear in opera at her old home. She paid visits to Germany and Sweden again before her departure for America in 1850. Just before sailing she appeared at Liverpool, for the first time in England, in an oratorio of Handel, and the soprano sang in The Messiah with superb success. She remained in America for nearly two years, being for a great part of the time engaged by P. T. Barnum. In Boston, on the 5th of February 1852, she married Otto Goldschmidt (1829–1897), whom she had met at Lübeck in 1849. For some years after her return to England, her home for the rest of her life, she appeared in oratorios and concerts, and her dramatic instincts were as strongly and perhaps as advantageously displayed in these surroundings as they had been on the stage, for the grandeur of her conceptions in such passages as the "Sanctus" of Elia, the intensity of conviction which she threw into the scene of the widow in the same work, or the religious fervour of "I know that my Redeemer liveth," could not have found a place in opera. In her later years she took an active interest in the Bach Choir, conducted by her husband, and not only sang herself in the chorus, but gave the benefit of her training to the ladies of the society. For some years she was professor of singing at the Royal College of Music. Her last public appearance was at Düsseldorf on the 20th of January 1870 when she sang in Ruth, an oratorio composed by her husband. She died at Malvern on the 2nd of November 1887. The supreme position she held so long in the operatic world was due not only to the glory of her voice, and the complete musicianship which distinguished her above all her contemporaries, but also to the naive simplicity of her acting in her favourite parts, such as Aminta, Alice or Agathe. In these and others she had the precious quality of conviction, and identified herself with the characters she represented with a thoroughness rare in her day. Unharmed by the perils of a stage career, she was a model of rectitude, generosity and straightforwardness, carrying the last quality into a certain blunt directness of manner that was sometimes rather startling.

LINDAU, PAUL (1839— ), German dramatist and novelist, the son of a Protestant pastor, was born at Magdeburg on the 3rd of June 1839. He was educated at the gymnasium in Halle and subsequently in Leipzig and Berlin. He spent five years in Paris to further his studies, acting meanwhile as foreign correspondent to German papers. After his return to Germany in 1863 he was engaged in journalism in Düsseldorf and Elberfeld. In 1870 he founded Das neue Blatt at Leipzig; from 1872 to 1881 he edited the Berlin weekly, Die Gegenwart; and in 1878 he founded the well-known monthly, Nord und Süd, which he continued to edit until 1904. Two books of travel, Aus Venetien (Düsseldorf, 1864) and Aus Paris (Stuttgart, 1865), were followed by some volumes of critical studies, written in a light, satirical vein, which at once made him famous. These were Harmlose Briefe eines deutschen Kleinbürglers (Leipzig, 2 vols., 1870), Moderner Menschen für große Kinder (Leipzig, 1873, and Liiterarisches Buchhaus, 3rd ed., Leipzig, 1873). He was appointed intendant of the court theatre at Meiningen in 1895, but removed to Berlin in 1899, where he became manager of the Berliner Theater, and subsequently, until 1905, of the Deutsches Theater. He had begun his dramatic career in 1868 with Marion, the first of a long series of plays in which he displayed a remarkable talent for stage effect and a command of witty and lively dialogue. Among the more famous were Maria und Magdalena (1872), Tante Therese (1876), Gräfin Lea (1879), Die Erste (1885), Der Abend (1886), Der Herr im Hause (1890), So ich dir (1903), and he adapted many plays by Dumas, Augier and Sardou for the German stage. Five volumes of his plays have been published (Berlin, 1873–1888). Some of his volumes of short stories acquired great popularity, notably Herr und Frau Bewer (Breslau, 1882) and Togenburg und andere Geschichten (Breslau, 1883). A novel-sequence entitled Berlin included Der Weg nach Westen (Stuttgart, 1886, 10th ed. 1903), Arme Mädchen (1857, 9th ed. 1895) and Späthes (1888, 8th ed. 1904). Later novels were Die Gehilfin (Breslau, 1894), Die Brüder (Dresden, 1895).
LINDAU—LINDESAY, JOHN

Der König von Sidon (Breslau, 1808). His earlier books on Molière (Leipzig, 1871) and Alfred de Musset (Berlin, 1877) were followed by some volumes of dramatic and literary criticism, Gesammelte Aufsätze (Berlin, 1875); Dramaturgische Blätter (Stuttgart, 2 vols., 1875; new series, Breslau, 1878, 2 vols.), Vorspiele auf dem Theater (Breslau, 1895).

His brother, Rudolf Lindau (b. 1829), was a well-known diplomatist and author. His novels and tales were collected in 1894 (Berlin, 6 vols.). The most attractive, such as Reisegeführten und der lange Holländer, deal with the life of European residents in the Far East.

See Hadligh, Paul Lindau als dramatischer Dichter (2nd ed., Berlin, 1876).

LINDAU, a town and pleasure resort in the kingdom of Bavaria, and the central point of the transit trade between that country and Switzerland, situated on two islands off the north-eastern shore of Lake Constance. Pop. (1903) 6531. The town is a terminus of the Vorarlberg railway, and of the Munich-Lindau line of the Bavarian state railways, and is connected with the mainland both by a wooden bridge and by a railway embankment erected in 1853. There are a royal palace and an old and a new town-hall (the older one having been built in 1422 and restored in 1886-1888), a museum and a municipal library with interesting manuscripts and a collection of Bibles, also classical, commercial and industrial schools. The harbour is much frequented by steamers from Constance and other places on the lake. There are also some Roman remains, the Heidenmauer, and a fine modern fountain, the Reichsbrunnen. Opposite the custom-house is a bronze statue of the Bavarian king Maximilian II., erected in 1856.

On the site now occupied by the town there was a Roman camp, the castrum Tiberii, and the authentic records of Lindau date back to the end of the 9th century, when it was known as Lintowa. In 1274, or earlier, it became a free imperial town and a member of the Swabian league, and in 1531 became a member of the league of Schmallkaden, having just previously accepted the reformed doctrines. In 1647 it was ineffectually besieged by the Swedes. In 1804 it lost its imperial privileges and passed to Austria, being transferred to Bavaria in 1805.

See Boulan, Lindau, vor allem jetzt (Lindau, 1872); and Steetnner, Führer durch Lindau und Umgebungen (Lindau, 1900).

LINGEN, a town in the Prussian province of Hanover, 3 m. S.W. by rail from the city of that name, of which it practically forms a suburb, and from which it is separated by the Ihme. Pop. (1903) 57,041. It has a fine modern town-hall, and a classical and other schools. Chief among its industries are machine building, weaving, iron and steel works and the manufacture of chemicals, india-rubber goods and carpets.

LINDESAY, ROBERT, of Pittscott (c. 1550-c. 1590), Scottish historian, of the family of the Lindesays of the Byres, was born at Pittscott, in the parish of Ceres, Fifeshire, which he held in 1584. His Historie and Cronicles of Scotland, the only work by which he is remembered, is described as a continuation of that of Hector Boece, translated by John Bellenden. It covers the period from 1437 to 1595, and, though it sometimes degenerates into a mere chronicle of short entries, is not without passages of great picturesque. Sir Walter Scott made use of it in Marmion; and, in spite of its inaccuracy in details, it is useful for the social history of the period. Lindesay's share in the Cronicles was generally supposed to end with 1565; but Dr Aeneas Mackay considers that the frank account of the events connected with Mary Stuart between 1565 and 1575 contained in one of the MSS. is by his hand and was only suppressed because it was too faithful in its record of contemporary affairs.

The Historie and Cronicles was first published in 1728. A complete edition of the text (2 vols.), based on the Laing MS., No. 218 in the university of Edinburgh, was published by the Scottish Text Society in 1899 under the editorship of Aeneas J. C. Mackay. The MS., formerly in the possession of John Scott of Halkshill, is fuller, and, though in a later hand, is, on the whole, a better representative of Lindesay's text.

LINDET, JEAN BAPTISTE ROBERT (1740–1825), French revolutionist, was born at Bernay (Eure). Before the Revolution he was an atosat at Bernay. He acted as procureur-syndic of the district of Bernay during the session of the Constituent Assembly. Appointed deputy to the Legislative Assembly and subsequently to the Convention, he attained considerable prominence. He was very hostile to the king, furnished a Rapport sur les crimes imputés à Louis Capet (10th of December 1792), and voted for the death of Louis without appeal or respite. He was instrumental in the establishment of the Revolutionary Tribunal and contributed to the downfall of the Girondists. As member of the Committee of Public Safety, he devoted himself particularly to the question of food-supplies, and it was only by dint of dogged perseverance and great administrative talent that he was successful in coping with this difficult problem. He had meanwhile been sent to suppress revolts in the districts of Rhône, Eure, Calvados and Finistère, where he had been able to pursue a conciliatory policy. Without being formally opposed to Robespierre, he did not support him, and he was the only member of the Public Safety who did not sign the order for the execution of Danton and his party. In a like spirit of moderation he opposed the Thermidorian reaction, and defended Barrère, Billaud-Varenne the Collot d’Herbois from the accusations launched against them on the 22nd of March 1795. Himself denounced on the 20th of May 1795, he was defended by his brother Thomas, but only escaped condemnation by the vote of amnesty of the 4th of Brumaire, year IV. (26th of October 1795). He was minister of finance from the 18th of June to the 9th of November 1799, but refused office under the Consulate and the Empire. In 1816 he was proscribed by the Restoration government as a regicide, and did not return to France until just before his death on the 17th of February 1825. His brother Thomas made some mark as a Constitutional bishop and member of the Convention.

See also Montier, Robert Lindet (Paris, 1890); H. Turpin, Thomas Lindet (Bernay, 1886); A. Montier, Correspondance de Thomas Lindet (Paris, 1899).

LINLEY, JOHN (1799–1865), English botanist, was born on the 5th of February 1799 at Catton, near Norwich, where his father, George Linley, author of A Guide to the Orchard and Kitchen Garden, owned a nursery garden. He was educated at Norwich grammar school. His first publication, in 1810, a translation of the Analyse du fruit of L. C. M. Richard, was followed in 1820 by an original Monographia Rosarum, with descriptions of new species, and drawings executed by himself, and in 1821 by Monographia Digitalium, and by "Observations on Pomaceae," contributed to the Linnean Society. Shortly afterwards he went to London, where he was engaged by J. C. Loudon to write the descriptive portion of the Encyclopaedia of Plants. In his labours on this undertaking, which was completed in 1829, he became convinced of the superiority of the "natural" system of Linnaeus followed in the Encyclopaedia; the conviction found expression in A Synopsis of British Flora, arranged according to the Natural Order (1829) and in An Introduction to the Natural System of Botany (1830). In 1829 Linley, who since 1822 had been assistant secretary to the Horticultural Society, was appointed to the chair of botany in University College, London, which he retained till 1860; he lectured also on botany from 1831 at the Royal Institution, and from 1836 at the Botanic Gardens, Chelsea. During his professorate he wrote many scientific and popular works, besides contributing largely to the Botanical Register, of which he was editor for many years, and to the Gardener's Chronicle, in which he had charge of the horticultural department from 1841. He was a fellow of the Royal, Linnean and Geological Societies. He died at Turnham Green on the 1st of November 1865.

Besides those already mentioned, his works include An Outline of the First Principles of Horticulture (1832), An Outline of the Structure and Physiology of Plants (1832), A Natural System of Botany (1836), The Fossil Flora of Great Britain (with William Hutton, 1831–1837), Flora Medica (1838), Theory of Horticulture (1840), The Vegetable Kingdom (1846), Folia Orchidaceae (1852), Descriptive Botany (1858).
LINDLEY, NATHANIEL LINDLEY, BARON (1828–1893), English judge, son of John Lindley (q.v.), was born at Acton Green, Middlesex, on the 9th of November 1828. He was educated at University College School, and studied for a time at University College, London. He was called to the bar at the Middle Temple in 1850, and began practice in the Court of Chancery. In 1855 he published An Introduction to the Study of Jurisprudence, consisting of a translation of the general part of Thibaut's System des Pandekten Rechts, with copious notes. In 1860 he published in two volumes his Treatise on the Law of Partnership, including its Application to Joint Stock and other Companies, and in 1862 a supplement including the Companies Act of 1862. This work has since been developed into two textbooks well known to lawyers as Lindley on Companies and Lindley on Partnership. He became a Q.C. in January 1872. In 1874 he was elected a bencher of the Middle Temple, of which he was treasurer in 1884. In 1875 he was appointed a justice of the common pleas, the appointment of a chancery barrister to a common-law court being justified by the fusion of law and equity then shortly to be brought about, in theory at all events, by the Judicature Acts. In pursuance of the charter he now received he became a justice of the common pleas division of the High Court of Justice, and in 1880 of the queen's bench division. In 1881 he was raised to the Court of Appeal and made a privy councillor. In 1897, Lord Justice Lindley succeeded Lord Esher as master of the rolls, and in 1900 he was made a lord of appeal in ordinary with a life peerage and the title of Baron Lindley. He resigned the judicial post in 1905. Lord Lindley was the last serjeant-at-law appointed, and the last judge to wear the serjeant's coif, or rather the black cap representing it, on the judicial wig. He married in 1858 Sarah Katherine, daughter of Edward John Teale of Leeds.

LINDLEY, WILLIAM (1808–1900), English engineer, was born in London on the 7th of September 1808, and became a pupil under Francis Giles, whom he assisted in designing the Newcastle and Carlisle and the London and Southampton railways. Leaving England about 1837, he was engaged for a time in railway work in various parts of Europe, and then returned, as engineer-in-chief to the Hamburg-Berghofen line to Hamburg, near which city he had received his early education, and to which he was destined to stand in much the same relation as Baron Haussmann to Paris. His first achievement was to drain the Hammerbrook marshes, and so add some 1400 acres to the available area of the city. His real opportunity, however, came with the great fire which broke out on the 5th of May 1842 and burned for three days. He was entrusted with the direction of the operations to check its spread, and the strong measures he adopted, including the blowing-up of the town hall, brought his life into danger with the mob, who professed to see in him an English agent charged with the destruction of the port of Hamburg. After the extinction of the fire he was appointed consulting engineer to the senate and town council, to the Water Board and to the Board of Works. He began with the construction of a complete sewerage system on principles which did not escape criticism, but which experience showed to be good. Between 1844 and 1849, water-works were established from his designs, the intake from the Elbe at Breslaven being at Rotthenburgsort. Subsidence tanks were useful for clarification, but in 1853, when he designed large extensions, he urged the substitution of sand-filtration, which, however, was not adopted until the cholera epidemic of 1822–1833 had shown the folly of the opposition directed against it. In 1846 he erected the Hamburg gas-works; public baths and wash-houses were built, and large extensions to the port executed according to his plans in 1854; and he supervised the construction of the Altona gas and water works in 1855. Among other services he rendered to the city may be mentioned the trigonometrical survey executed between 1848 and 1860, and the conduct of the negotiations which in 1852 resulted in the sale of the "Steelyard" on the banks of the Thames belonging to it jointly with the two other Hanseatic towns, Bremen and Lübeck. In 1866 he left Hamburg, and during the remaining nineteen years of his professional practice he was responsible for many engineering works in various European cities, among them being Frankfort-on-the-Main, Warsaw, Pest, Düsseldorf, Galatz and Basel. In Frankfort he constructed sewage works on the same principles as those he followed in Hamburg, and the system was widely imitated not only in Europe, but also in America. He was also consulted in regard to water-works at Berlin, Kiel, Stralsund, Stettin and Leipzig; he advised the New River Company of London on the adoption of the constant supply system in 1851; and he was commissioned by the British Government to carry out various works in Heligoland, including the big retaining wall "Am Falm." He died at Blackheath, London, on the 22nd of May 1900.

LINDO, MARK PRAGER (1819–1879), Dutch prose writer, of English-Jewish descent, was born in London on the 18th of September 1819. He went to Holland when nineteen years of age, and once established himself as a private teacher of the English language, he soon made up his mind to remain. In 1842 he passed his examination at Arnhem, qualifying him as a professor of English in Holland, subsequently becoming a teacher of the English language and literature at the gymnasium in the Stadhoudersstraat in Amsterdam. In 1853 he was appointed a regular professor of English at the Royal Military Academy in Breda. Meanwhile Lindo had obtained a thorough grasp of the Dutch language, partly during his student years at Utrecht University, where in 1854 he gained the degree of doctor of literature. His proficiency in the two languages led him to translate into Dutch several of the works of Dickens, Thackeray and others, and afterwards also of Fielding, Sterne and Walter Scott. Some of Lindo's translations bore the imprint of hasty and careless work, and all were very unequal in quality. His name is much more likely to endure as the writer of humorous original sketches and novelllets in Dutch, which he published under the pseudonym De Oude Herr Smits ("Old Mr Smits"). Among the most popular are: Brieven en Ontboezemingen ("Letters and Confessions," 1853, with three Continuations); Familie van Ons ("Family of Ours," 1853); Bekenennisen eener Jonge Dame ("Confessions of a Young Lady," 1853); Uitrekels uit het Dagboek van Wijlen den Heer Janus Snoepe ("Extracts from the Diary of the late Mr Jan Snoepe," 1854); and, particularly, Afdrukken van Indrukken ("Impressions from Impressions," 1854, reprinted many times). The last-named was written in collaboration with Lodewyk Mulder, who contributed some of its most whimsicalities of Dutch life and character, which, for that reason, are almost untranslatable. Lodewyk Mulder and Lindo also founded together, and carried on, for a considerable time alone, the Nederlandsche Spectator ("The Dutch Spectator"), a literary weekly, still published at The Hague, which bears little resemblance to its English prototype, and which perhaps reached its greatest popularity and influence when Vosmaer contributed to it a brilliant weekly letter under the fanciful title of Vlugmaren ("Swifts"). Lindo's serious original Dutch writings he published under his own name, the principal one being De Ophomst en Ontwikkeling van het Engelsche Volk ("The Rise and Development of the British People," 2 vols. 1868–1874)—a valuable history. Lodewyk Mulder published in 1877–1879 a collected edition of Lindo's writings in five volumes, and it has since been a popular reader or textbook of Dutch in the primary schools in the province of South Holland in 1865, a post he held until his death at The Hague on the 9th of March 1879.

LINDSAY, the family name of the earls of Crawford. The family is one of great antiquity in Scotland, the earliest to settle in that country being Sir Walter de Lindsesia, who attended David, earl of Huntingdon, afterwards King David I., in his colonization of the Lowlands early in the 12th century. The descendants of Sir Walter divided into three branches, one of which held the baronies of Lamberton in Scotland, and Kendal and Molesworth in England; another held Luffness and Crawford in Scotland and half Limes in England; and a third held Breneville and Byres in Scotland and certain lands, not by baronial tenure, in England. The heads of all these branches sat as barons in the Scottish parliament for more than two hundred years before the elevation of the chief of the house to an earldom in 1398. The
LINDSAY—LINE

Lindseys held the great mountain district of Crawford in Clydesdale, from which the title of the earldom is derived, from the 12th century till the close of the 17th, when it passed to the Douglas earls of Angus. See Crawford, Earls of.

See A. W. C. Lindsay, afterwards earl of Crawford, Lives of the Lindseys, or a Memoir of the Houses of Crawford and Belcarres (3 vols., 1843 and 1856).

LINDSAY, a town and port of entry of Ontario, Canada, and capital of Victoria county, on the Scugog river, 57 m. N.E. of Toronto by rail, on the Canadian Pacific railway, and at the junction of the Port Hope and Haliburton branches and the Midland division of the Grand Trunk railway. Pop. (1901) 7093.

It has steamboat communication, by way of the Thousand islands, with New York, and mail boats run to St. Lawrence. It contains saw and grist mills, agricultural implement and other factories.

LINDSEY, THEOPHILUS (1733–1808), English theologian, was born in Middlewich, Cheshire, on the 20th of June 1733, and was educated at the Leeds Free School and at St John's College, Cambridge, where in 1747 he became a fellow. For some time he held a curacy in Spitfieldals, London, and from 1754 to 1756 he travelled on the continent of Europe as tutor to the young duke of Northumberland. He was then presented to the living of Kirkby-Wiske in Yorkshire, and after exchanging it for that of Piddletown in Dorsetshire, he removed in 1763 to Catterick in Yorkshire. Here about 1764 he founded one of the first Sunday schools in England. Meanwhile he had begun to entertain anti-Trinitarian views, and to be troubl'd in conscience about the worship connected with the Anglican belief; since 1769 the intimate friendship of Joseph Priestley had served to foster his scruples, and in 1771 he united with Francis Blackburne, archdeacon of Cleveland (his father-in-law), John Jebb (1736–1786), Christopher Wvill (1740–1822) and Edmund Law (1743–1787), bishop of Carlisle, in preparing a petition to parliament with the prayer that clergymen of the church and graduates of the universities might be relieved from the burden of subscribing to the thirty-nine articles, and "restored to their undoubted rights as Protestants of interpreting Scripture for themselves." Two hundred and fifty signatures were obtained, but in February 1772 the House of Commons declined even to receive the petition by a majority of 217 to 71; the adverse vote was repeated in the following year, and in the end of 1773, seeing no prospect of obtaining within the church the relief to which his conscience demanded, Lindsey resigned his vicarage. In April 1774 he began to conduct Unitarian services in a room in Essex Street, Strand, London, where first a church, and afterwards the Unitarian offices, were established. Here he remained till 1793, when he resigned his charge in favour of John Disney (1746–1819), who like himself had left the established church and had become his colleague. He died on the 3rd of November 1808.

Lindsey's chief work is An Historical View of the State of the Unitarian Doctrine and Worship from the Reformation to our own Times (1783); in it he claims, amongst others, Burnet, Tillotson, S. Clarke, Hody, and Sir I. Newton for the Unitarian view. His other publications include Apology on Resigning the Vicarage of Cutlerick (1774), and Sequel to the Apology (1776); The Book of Common Prayer, corrected from the original Office of the late Dr. Stillingfleet (1774); Dissertations on the Preface to St John's Gospel and on praying to Jesus Christ (1775); Vindications Priestianae (1788); Conversations upon Christian Idolatry (1792); and Conversations on the Divine Government, showing that everything is from God, and good to all (1802). Two volumes of Sermons, with appropriate prayers annexed, were published posthumously in 1810; and a volume of Memoirs, by Thomas Belsham, appeared in 1812.

LINDBRÖM, GUSTAF (1829–1901), Swedish palaeontologist, was born at Wisby in Gotland on the 27th of August 1829. In 1848 he entered the university at Upsala, and in 1854 he took his doctor's degree. Having attended a course of lectures in Stockholm by S. L. Löven, he became interested in the zoology of the Baltic, and published several papers on the invertebrate fauna, and subsequently on the fishes. In 1856 he became a school teacher, and in 1859 a master in the grammar school at Wisby. His leisure was devoted to researches on the fossils of the Silurian rocks of Gotland, including the corals, brachiopods, gastropods, pteropods, cephalopods and crustacea. He described also remains of the fish Cyatharis from Wenlock Beds, and (with T. Thorell) a scorpion Palaeopygus from Ludlow Beds at Wisby. He determined the true nature of the operculated coral Calcarea; and while he described organic remains from other parts of northern Europe, he worked especially at the Palaeozoic fossils of Sweden. He was awarded the Murchison medal by the Geological Society of London in 1853. In 1876 he was appointed keeper of the fossil Invertebrata in the State Museum at Stockholm, where he died on the 16th of May 1901.

See obituary (with portrait), by F. A. Bather, in Geol. Mag. (July 1901), p. 333.

LINDUS, one of the three chief cities of the island of Rhodes, before their synoecism in the city of Rhodes. It is situated on the E. side of the island, and has a finely placed acropolis on a precipitous hill, and a spacious plain below. Excavations have discovered the early temple of Athena Lindia on the Acropolis, and splendid Propylaea and a staircase, resembling those at Athens. The sculptors of the Laocoon are among the priests of Athena Lindia, whose names are recorded by inscriptions. Some early temples have also been found, and inscriptions cut on the rock recording the sacrifices known as Boukāstra. There are also traces of a theatre and rock-cut tombs. On the Acropolis is a castle, built by the knights in the 14th century, and many houses in the town show work of the same date.

See Rhodes; also Chr. Blinkenberg and K. F. Klink, Exploration arch. de Rhodos (Copenhagen, 1904–1907).

LINE, a word of which the numerous meanings may be deduced from the primary idea of something drawn, a succession of objects in a row, a mark or stroke, a course or line in any particular direction. The word is derived from the Lat. linea, where all these meanings may be found, but some applications are due more directly to the Fr. ligne. Lina, in Latin, meant originally "something made of hemp or flax," hence a cord or thread, from linum, flax. "Line" in English was formerly used in the sense of flax, but the use now only survives in the technical name for the fibres of flax when separated by heckling from the tow (see LINEN). The ultimate origin is also seen in the verb "to line," to cover something on the inside, originally used of the "lining" of a garment with linen.

In mathematics several definitions of the line may be framed according to the aspect from which it is viewed. The synthetical definition of a line is the notion of line on the basis of Euclid's definition, γραμμή, δὲ μέρος ἐξάρατος ("a line is widthless length"), and in a subsequent definition he affirms that the boundaries of a line are points, γραμμή δὲ περίπατος σημεία. The line appears in definition 6 as the boundary of a surface: ἐστίν γὰρ περίπατος γραμμαί ("the boundaries of a surface are lines"), Another synthetical definition, also treated by the ancient Greeks, but not by Euclid, regards the line as generated by the motion of a point (διόνυσμα), and, in a similar manner, the "surface" was regarded as the flux of a line, and a "solid" as the flux of a surface. Proclus adopts this view, styling the line ἄπριφη in respect of this capacity. Analytical definitions, although not finding a place in the Euclidean treatise, have advantages over the synthetical derivation. Thus a line is the locus of a point whose co-ordinates define it, the edges a line, and the corners a point; or a section of a solid may define the surface, a section of a surface the line, and the section of a line the "point." The notion of dimensions follows readily from either system of definitions. The solid extends three ways, i.e. it has length, breadth and thickness, and is therefore threedimensional; the surface has breadth and length and is therefore two-dimensional; the line has only extension and is unidimensional; and the point, having neither length, breadth nor thickness but only position, has no dimensions.

The definition of a "straight" line is a matter of much complexity. Euclid defines it as the line which lies evenly with respect to the points on itself—εὐθεῖα γραμμή κατὰ ἑαυτὸν τοῦ ἕως ἑαυτῆς σημεία, Plato defined it as the line having its middle point hidden by the ends, a definition of no purpose since it only defines the line by the path of a ray of
Light. Archimedes defines a straight line as the shortest distance between two points. A better criterion of rectilinearity is that of Simplicius, an Arabian commentator of the 5th century: *Linea recta est quaeunque super duas ipsius extremitates rotata non movetur de loco suo ad alium locum* ("a straight line is one which when rotated about its two extremities does not change its position"). This idea was employed by Leibnitz, and most auspiciously by Gieronimo Saccheri in 1733.

The drawing of a straight line between any two given points forms the subject of Euclid's first postulate—*καθότου ἀπὸ παυκοῦ σημείου εἰς τὸν σημεῖον εὐθεία γραμμῆς*—and the producing of a straight line continuously in a straight line is treated in the second postulate—*καὶ περιπεριμένειν εὐθείαν κατὰ τὸ συγκεῖς εὐθείας κυπαλικές*. For a detailed analysis of the geometrical notion of the line and rectilinearity, see W. B. Frankland, *Euclid's Elements* (1905). In analytical geometry the right line is always representable by an equation or equations of the first degree; thus in Cartesian coordinates of two dimensions the equation is of the form \(Ax + By + C = 0\), where \(A\) and \(B\) are in the coordinate axes. Suppose \(A\) and \(B\) are both non-zero. In three-dimensional coordinates, the line is represented by two linear equations. (See GEOMETRY, ANALYTICAL.) *Line geometry* is a branch of analytical geometry in which the line is the element, and not the point as with ordinary analytical geometry (see GEOMETRY, LINE).

**LINE-ENGRAVING,** on plates of copper or steel, the method of engraving (*q.v.*), in which the line itself is hollowed, whereas it is woodcut in the woodcut when the line is to print black it is left in relief, and only white spaces and white lines are hollowed.

The art of line engraving has been practised from the earliest ages. The prehistoric Aztec hatchet given to Humboldt in Mexico was just as truly *engraved* as a modern copper-plate which may convey a design by Flaxman; the Aztec engraving is ruder than the European, but it is the same art. The important discovery which made line engraving one of the multiplying arts was the discovery how to print an incised line, which was hit upon at last by accident, and known for some time before its real utility was suspected. Line engraving in Europe does not owe its origin to the woodcut, but to the chiseling on goldsmiths' work. The goldsmiths of the middle of the 15th century, working in the same metals to engraving the works by means of engraving after which they filled up the hollows produced by the burin with a black enamel made of silver, lead and sulphur, the result being that the design was rendered much more visible by the opposition of the enamel and the metal.

An engraved design filled up in this manner was called a *niello.* Whilst a niello was in progress the artist could not see it so well if the enamel were already in the lines, yet he did not like to put in the hard enamel prematurely, as when once it was set it could not easily be got out again. He therefore took a sulphur cast of his niello in progress, on a matrix of fine clay, and filled up the lines in the sulphur with lampblack, thus enabling himself to judge of the state of his engraving. At a later period it was discovered that a proof could be taken on damped paper by filling the engraved lines with a certain ink and dipping the paper in the ink of them. This was the beginning of plate printing. The niello engravers thought it a convenient way of proving their work—the metal artist—when the metal was the thing they had to cast, but they saw no further into the future. They went on engraving niello just the same to ornament plate and furniture; nor was it until the 16th century that the new method of printing was carried out to its great and wonderful results. There are, however, certain differences between plate-printing and block-printing which affect the essentials of art. When paper is driven *into* a line so as to fetch the ink out of it, the line may be of unimaginary fineness, it will print all the same; but when the paper is only pressed *upon* a raised line, the line must have some appreciable thickness; the wood engraving, therefore, can never—except in a *tour de force*—be so delicate as plate engraving. Again, not only does plate-printing excel block-printing in delicacy; it excels it also in force and depth. There never was, and there will never be, a woodcut line having the power of a deep line in a plate, for in block-printing the line is only a blackened surface of paper which is pressed, whereas in plate-printing it is a cast with an additional thickness.

The most important of the tools used in line-engraving is the burin, which is a bar of steel with one end fixed in a handle rather like a mushroom with one side cut away, the burin itself being shaped so that the cutting end when sharpened takes the form of a lozenge, point downwards. The burin acts exactly like a plough; it makes a furrow and turns out a shaving of metal as the plough turns the soil of a field. The burin, however, is pushed while the plough is pulled, and this peculiar character of the burin, or graver, as a pushed instrument at once establishes a wide separation between it and all the other instruments employed in the arts of design, such as pencils, brushes, pens and etching needles.

The elements of engraving with the burin upon metal will be best understood by an example of a very simple kind, as in the letter B of letters. The capital letter B can be itself the rudiments of an engraver's education. As at first drawn, before the blacks are inserted, this letter consists of two perpendicular lines and four curves, all the curves differing from each other. Suppose, then, that the engraver has to make a B, he will scratch those lines and curves reversely. Then the next thing is to cut out the blacks (not the whites, as in wood engraving), and this would be done with two different burins. The engraver would get his vertical black line by a powerful ploughing with the burin in the burin; the surperfine lines are then taken out some copper in the thickest parts of the two curves. Done, he would then take a finer burin and work out the gradation from the thick line in the middle of the thin extremities which touch the perpendicular. When there is much gradation in a line the darker parts of it are often gradually ploughed out by returning it over and over again. The hollows so produced are afterwards filled with printing ink, just as the hollows in a niello were filled with sulphur; the printing ink is then poured from the smooth surface of the copper, damped paper is laid upon it, and driven into the hollowed letter by the pressure of a revolving cylinder; it fetches the ink out, and you have your letter B in intense black upon a white ground.

When the surface of a metal plate is sufficiently polished to be used for engraving, the slightest scratch upon it will print as a black line, the degree of blackness being proportioned to the depth of the lines. As the engraved plate from which printing cards are printed is a good example of some elementary principles of engraving; it contains thin lines and thick ones, and a considerable variety of curves. An elaborate line engraving, if it is a pure line engraving and nothing else, will contain only these simple elements in different combinations. The real line engraver is always engraving a line more or less broad and deep in one direction or another; he has no other business than this.

In the early Italian and early German prints, the line is used with such perfect simplicity of purpose that the methods of the artists are as obvious as if we saw them actually at work.

The student may soon understand the spirit and technical quality of the earliest Italian engraving by giving his attention to a few of the series which used erroneously to be called the "Playing Cards of Mantega," but which have been shown by Mr Sidney Colvin to represent "a kind of encyclopedia of knowledge." The history of these engravings is obscure. They are supposed to be Florentine; they are certainly Italian; and their technical manner is called that of Baccio Baldini. But their style is as clear as a style can be, as clear as the artist's conception of his work. In all these figures the outline is the main thing, and next to that the lines which mark the moulding of the paper, lines quite classical in purity of form and severity of selection, and especially characteristic in this, that they are always really engraver's lines, such as may naturally be done with the burin, and never imitate the freer line of the pencil or etching needle. Shading is used in the greatest moderation with thin straight strokes of the burin, that never overpower the stronger organic lines of the design. Of chiaroscuro, in any complete sense, there is none. The sky behind the figures is represented by white paper, and the foreground is sometimes occupied by flat decorative engraving, much nearer in feeling to calligraphy than to modern painting. Sometimes there is a cast shadow, but it is not studied, and is only used to give relief. In this
LINE-ENGRAVING

early metal engraving the lines are often crossed in the shading, whereas in the earliest woodcuts they are not; the reason being that when lines are incised they can as easily be crossed as not, whereas, when they are reserved, the crossing involves much labour of a non-artistic kind. Here, then, we have pure line-engraving with the burin, that is, the engraving of the pure line patiently studied for its own beauty, and exhibited in an abstract manner, with care for natural form combined with inattention to the effects of nature. Even the forms are idealized, especially in the cast of draperies, for the express purpose of exhibiting the line to better advantage. Such are the characteristics of those very early Italian engravings which were attributed erroneously to Mantegna. When we come to Mantegna himself we find a style equally decided. Drawing and shading were for him two entirely distinct things. He did not draw and shade at the same time, as a modern chiaroscuro would, but he first got his outlines and the patterns on his dresses all very accurate, and then threw over them a veil of shading, a very peculiar kind of shading, all the lines being straight and all the shading diagonal. This is the primitive method, its peculiarities being due, not to a received self-restrained, but to a combination of natural genius with technical inexperience, which made the early Italians at once desire and discover the simplest and easiest methods. Whilst the Italians were shading with straight lines the Germans had begun to use curves, and as soon as the Italians saw good German work they tried to give to their burins something of the German suppleness.

The characteristics of early metal engraving in Germany are seen to perfection in Martin Schongauer and Albert Dürer, who, though with striking differences, had many points in common. Schongauer died in 1488; whilst the date of Dürer's death is 1528. Schongauer was therefore a whole generation before Dürer, yet not greatly inferior to him in the use of the burin, though Dürer has a much greater reputation, due in great measure to his singular imaginative powers. Schongauer is the first great German engraver known by name, but he was preceded by an unknown German master, called "the Master of 1466," who had Gothic notions of art (in strong contrast to the classicism of Boccio Baldini), but used the burin skilfully, conceiving of line and shade as separate elements, yet shading with an evident desire to follow the form of the thing shaded, and with lines in various directions. Schongauer's art is a great stride in advance, and we find in him an evident pleasure in the bold use of the burin. Outline and shade, in Schongauer, are not nearly so much separated as in Boccio Baldini, and the shading, generally in curved lines, is far more masterly than the straight shading of Mantegna. Dürer continued Schongauer's curved shading, with increasing manual delicacy and skill; and as he found himself able to perform feats with the burin which amused both himself and his buyers, he over-loads his plates with quantities of living and inanimate objects, each of which he finished with as much care as if it were the most important thing in the composition. The engravers of those days had no conception of any necessity for subordinating one part of their work to another; they drew, like children, first one object and, and another object, and so on until the plate was furnished from top to bottom and from the left side to the right. Here, of course, is an element of facility in primitive art which is denied to the modern artist. In Dürer all objects are on the same plane. In his "St Hubert" (otherwise known as "St Eustace") of c. 1505, the stag is quietly standing on the horse's back, with one hoof on the saddle, and the kneeling knight looks as if he were tapping the horse on the nose. Dürer seems to have perceived the mistake about the stag, for he put a tree between us and the animal to correct it, but the stag is on the horse's back nevertheless. This ignorance of the laws of effect is least visible and obtrusive in plates which have no landscape distances, such as "The Coat of Arms with the Death's Head" (1503) and "The Coat of Arms with the Cock" (c. 1532).

Dürer's great manual skill and close observation made him a wonderful engraver of objects taken separately. He saw and rendered all objects; nothing escaped him; he applied the same intensity of study to everything. Though a thorough student of the nude—witness his Adam and Eve (1504) and other plates— he would pay just as much attention to the curves of a galatess as to the development of a muscle; and though man was his main subject, he would study dogs with equal care (see the five dogs in the "St Hubert"), as well as pigs (see the "Prodigal Son," c. 1495); and at a time when landscape painting was unknown he studied every clump of trees, every visible trunk and branch, nay, every foreground plant, and each leaf of it separately. In his buildings he saw every brick like a bricklayer, and every joint in the woodwork like a carpenter. The immense variety of the objects which he engraved was a training in suppleness of hand. His lines go in every direction, and are made to render both the undulations of surfaces (see the plane in the Melencolia, 1514) and their texture (see the granular texture of the stones in the same print).

From Dürer we come to Italy again, through Marcantonio, who copied Dürer, translating more than sixty of his woodcuts upon metal. It is one of the most remarkable things in the history of art, that a man who had trained himself by copying northern engravings, and who had learned Gothicism, should have become so soon afterwards the great engraver of the Italians. Rubens was much pleased with his work and aided him by personal advice. Yet, although Raphael was a painter, and Marcantonio his interpreter, the reader is not to infer that engraving had as yet subordinated itself to painting. Raphael himself evidently considered engraving a distinct art, for he never once set Marcantonio to work from a picture, but always (much more judiciously) gave him drawings, which the engraver might interpret without going outside his own art; consequently Marcantonio's works are always genuine engravings, and are never pictorial. Marcantonio was an engraver of remarkable power. In him the real pure art of line-engraving reached its maturity. He retained much of the early Italian manner in his backgrounds, where its simplicity gives a desirable sobriety; but his figures are boldly modelled in curved lines, crossing each other in the darker shades, but left single in the passages from dark to light, and breaking away in fine dots as they approach the light itself, which work is the result of a study of the line in pure paper. A school of engraving was thus founded by Raphael, through Marcantonio, which cast aside the minute details of the early schools for a broad, harmonious treatment.

The group known as the engravers of Rubens marked a new development. Rubens understood the importance of engraving as a means of increasing his fame and wealth, and directed Vorsterman and others. The theory of engraving at that time was that it ought not to render accurately the local colour of painting, which would appear wanting in harmony when dissociated from the hues of the picture; and it was one of the anxieties of Rubens so to direct his engravers that the result might be a fine plate independently of what he had painted. To this end he helped his engravers by drawings, in which he sometimes indicated what he thought the best direction for the lines. Rubens liked Vorsterman's work, and scarcely corrected it, a plate he especially approved being "Susannah and the Elders," which is a learned piece of work well modelled, and shaded everywhere on the figures and costumes with fine curved lines, the straight lines being used only for the masonry. Vorsterman quitted Rubens after executing fourteen important plates, and was succeeded by Paul Pontius, then a youth of twenty, who went on engraving from Rubens with increasing skill until the painter's death. Boetius a Bolswerte engraver from Rubens towards the close of his life, and his brother Schelte a Bolswerte engraved more than sixty compositions of Rubens, of the most varied character, including hunting scenes and landscapes. This brings us to the engraving of landscape as a separate study. Rubens treated landscape in a broad comprehensive manner, and Schelte's way of engraving it was also broad and comprehensive. The lines are long and often undulating, the cross-hatchings bold and rather obtrusive, for they often substitute unpleasant reticulations for the refinement and mystery of nature, but it was a beginning, and a vigorous beginning. The technical developments of engraving under the influence of
Rubens may be summed up briefly as follows: (1) The Italian outine had been discarded as the chief subject of attention, and modelling had been substituted for it; (2) broad masses had been substituted for the minutely finished detail of the northern schools; (3) a system of light and dark had been adopted which was not pictorial, but belonged especially to engraving, which it rendered (in the opinion of Rubens) more harmonious.

The history of line-engraving, from the time of Rubens to the beginning of the 19th century, is rather that of the vigorous and energetic application of principles already accepted than any new development. From the two sources already indicated, the school of Raphael and the school of Rubens, a double tradition flowed to England and France, where it mingled and directed English and French practice. The first influence on English line-engraving was Flemish, and came from Rubens through Van Dyck, Vorsterman, and others; but the English engravers soon underwent French and Italian influences, for although Payne learned from a Fleming, Falthorne studied in France under Philippe de Champagne the painter and Robert Nanteuil the engraver. Sir Robert Strange studied in France under Philippe Lebas, and then five years in Italy, where he saturated his mind with Italian art. French engravers came to England as they went to Italy, so that the art of engraving became in the 18th century cosmopolitan. In figure-engraving the outline was less and less insisted upon. Strange made it his study to soften and lose the outline. Meanwhile, the great classical Renaissance school, with Gérard Audran at its head, had carried forward the art of modelling with the burin, and had arrived at great perfection of a sober and dignified kind. Audran was very productive in the latter half of the 17th century, and died in 1703, after a life of severe self-direction in labour, the best external influence he underwent being that of the painter Nicolas Poussin. He made his work more rapid by the use of etching, but kept it entirely subordinate to the work of the burin. One of the finest of his large plates is "St John Baptizing," from Poussin, with groups of figures and groups of small figures in the foreground and background of grand classical landscape, all executed with the most thorough knowledge according to the ideas of that time. The influence of Claude Lorrain on the engraving of landscape was exercised less through his etchings than his pictures, which compelled the engravers to study delicate distinctions in the values of light and dark. Through Woollett and Vivares, Claude exercised an influence on landscape engraving almost equal to that of Raphael and Rubens on the engraving of the figure, though he did not direct his engravers personally.

In the 17th century line-engraving received first an impulse and finally a check. The impulse came from the growth of public wealth, the increasing interest in art and the increase in the commerce of art, which, by means of engraving, fostered in England mainly by John Boydell, penetrated into the homes of the middle classes, as well as from the growing demand for illustrated books, which gave employment to engravers of first-rate ability. The check to line-engraving came from the desire for cheaper and more rapid methods, a desire satisfied in various ways, but especially by etching and by the various kinds of photography. Nevertheless, the 17th century produced most highly accomplished work in line-engraving, both in the figure and in landscape. Its characteristics, in comparison with the work of other centuries, were chiefly a more thorough and delicate rendering of local colour, light and shade, and texture. The elder engravers could draw as correctly as the moderns, but they either neglected these elements or admitted them sparingly, as opposed to the spirit of their art. In a modern engraving from Landseer may be seen the blackness of a man's boots (local colour), the soft roughness of his coat (texture), and the exact value in light and dark of his face and costume against the cloudy sky. Nay more, there is to be found every sparkle on bit, boot and stirrup. Modern painting pays more attention to texture and chiaroscuro than classical painting did, and engraving necessarily followed in the same directions. But there is a certain sameness in pure line-engraving more favourable to some forms and textures than to others. This sameness of line-engraving, and its costliness, led to the adoption of mixed methods, extremely prevalent in commercial prints from popular artists. In the well-known prints from Rosa Bonheur, for example, by T. Landseer, H. T. Ryall, and C. G. Lewis, the tone of the skies is got by machine-ruling, and so is much undertone in the landscape; the fur of the animals is all etched, and so are the foreground plants, the real burin work being used sparingly where most favourable to texture. Even in the exquisite engravings after Turner, by Cooke, Goodall, Wallis, Miller, Willmore, and others, who reached a degree of delicacy in light and shade far surpassing the work of the old masters, the engravers had recourse to etching, finishing with the burin and dry point. Turner's name may be added to those of Raphael, Rubens and Claude in the list of painters who have had a special influence upon engraving. The speciality of Turner's influence was in the direction of delicacy of tone. In this respect the Turner vignettes to Roger's poems were a high-water mark of human attainment, not likely ever to be surpassed.

The record of the art of line-engraving during the last quarter of the 19th century is one of continued decay. Technical improvements, it was hoped, might save the art; it was thought by some that the slight revival resultant on the turning back of the burin's cutting-point—whereby the operator pulled the tool towards him instead of pushing it from him—might effect much, in virtue of the time and labour saved by the device. But by the beginning of the 20th century pictorial line-engraving in England was practically non-existent, and, with the passing of Jeens and Stacpoole, the spasmodic demand by publishers for engravers to engrave new plates remained unanswered. Mr C. W. Sherborn, the exquisite and facile designer and engraver of book-plates, has scarcely been surpassed in his own line, but his art is mainly heraldic. There are now no men capable of such work as that with which Doo, J. H. Robinson, and their fellows maintained the credit of the English School. Line-engraving has been killed by etching, mezzotint and the mixed means of photogravure. The time, indeed, when engraving was able to exert the artistic objection that the personality of the line-engraver stands obtrusively between the painter and the public; it is rather that the public refuse to wait for several years for the proofs for which they have subscribed, when by another method they can obtain their plates more quickly. An important line plate may occupy a prodigious time in the engraving; J. H. Robinson's "Napoleon and the Pope" took about twelve years. The invention of steel-facing a copper plate would now enable the engraver to proceed _expeditiously_; but even in this case he can no more compete with the etcher than the mezzotint-engraver can keep pace with the photogravure manufacturer.

The Art Union of London in the past gave encouragement it could; but with the death of J. Stephenson (1886) and F. Bacon (1887) it was evident that all hope was gone. John Saddler at the end was driven, in spite of his capacity to do excellent work, to spend most of his time in assisting Thomas Landseer to rule the skies on his plates, simply because there was not enough line-engraving to do. Since then there was some promise of a revival, and Mr Bourne engraved a few of the pictures by Gustave Doré. But little followed. The last of the line-engravers of Turner's pictures died in the person of Sir Daniel Wilson (d. 1892), who, recognizing the hopelessness of his early profession, laid his graver aside, and left Europe for Canada and eventually became president of the university of Toronto.

If line-engraving still flourishes in France, it is due not a little to official encouragement and to intelligent fostering by collectors and connoisseurs. The prizes offered by the École des Beaux Arts would probably not suffice to give vitality to the art but for the employment afforded to the finished artist by the "Chalcographie du Musée du Louvre," in the name of which commissions are judiciously distributed. At the same time, it must be recognized that not only are French engravers less busy than they were in days when line-engraving was the only "important" method of picture-translation, but they work for the most part for much smaller rewards. Moreover, the class of the work has entirely changed, partly through the
LINEN AND LINEN MANUFACTURES

reduction of prices paid for it, partly through the change of taste and fashion, and partly, again, through the necessities of the situation. That is to say, that public impatience is but a partial factor in the abandonment of the fine broad sweeping trough cut deep into the copper which was characteristic of the earlier engraving, either simply cut or crossed diagonally so as to form the series of "lozenges" typical of engraving at its finest and grandest period. That method was slow; but scarcely less slow was the shallower work rendered possible by the steel plate by reason of the much greater degree of elaboration of which such plates were capable, and which the public was taught—mainly by Finden—to expect. The French engravers were therefore driven at last to simplify their work if they were to satisfy the public and live by the burin. To compensate for loss of colour, the art developed in the direction of elegance and refinement. Gaillard (d. 1887), Blanchard, and Alphonse François (d. 1888) were perhaps the earliest chiefs of the new school, the characteristics of which are the substitution of exquisite greys for the rich blacks of old, simplicity of method being often allied to extremely high elaboration. Yet the aim of the modern engraver has always been, while pushing the capability of his own art to the farthest limit, to retain throughout the individual and personal qualities of the master whose work is translated on the plate. The height of perfection to which the art is reached is seen in the triptych of Mantegna by Achille Jacquet (d. 1909), to whom perhaps be accorded the first place among several engravers of the front rank. This "Passion" (from the three pictures in the Louvre and at Tours, forming the predella of the San Zeno altarpiece in Verona) not only conveys the forms, sentiment, and colour of the master, but succeeds also in rendering the peculiar luminosity of the originals. Jacquet, who gained the Prix de Rome in 1870, also translated pictures of Sir Joshua Reynolds, and engraved fine plates after Paul Dubois, Cabanel, Bouguereau, Meissonier and Détaille. The freedom of much of his work suggests an affinity with etching and dry-point; indeed, it appears that he uses the etching-needle and acid to lay in some of his groundwork and outlines. Léopold Flameng's engraving after Jan van Eyck ("Engage with the Donor") in the Louvre, is one of the most admirable works of its kind, retaining the quality and sentiment of the master, extreme minuteness and elaboration notwithstanding. Jules Jacquet is known for his work after Meissonier (especially the "Friedland") and after Bonnat; Adrien Didier for his plates after Holbein ("Anne of Cleves"), Raphael, and Paul Veronese, among the Old Masters, and Bonnat, Bouguereau, and Roybet among the new. Jazinski (Botticelli's "Primavera"); Sulpis (Mantegna and Gustave Moreau), Patricot (Gustave Moreau), Burney, and Champollon (d. 1901), have been among the leaders of the modern school. Their object is to secure the faithful transcript of the painter they reproduce, while readily sacrificing the power of the old method, which, whatever its force and its beauty, was easily acquired by mediocre artists of technical ability who were nevertheless unable to appreciate or reproduce anything beyond mechanical excellence.

The Belgian School of engraving is not without vitality. Gustave Biot was equally skilful in portrait and subject (engraving after Gallait, Cabanel, Gustave Doré, among his best work); A. M. Danse executed plates after leading painters, and elaborated an effective "mixed method" of graver-work and dry-point; and de Meeran has engraved a number of good plates; but private patronage is hardly sufficient in Belgium to maintain the school in a state of prosperous efficiency.

In Germany, as might be expected, line-engraving retains not a little of its popularity in its more orthodox form. The novel Stauffer-Bern method, in which freedom and lightness are obtained with such delicacy that the fine lines, employed in great numbers, run into tone, and yield a supposed advantage in modelling, has not been without appreciation. But the more usual virtue of the graver has been best supported, and many have worked in the old-fashioned manner. Friedrich Zimmer-
In 1810 Napoleon I. offered a reward of one million francs to any inventor who should devise the best machinery for the spinning of flax yarn. Within a few weeks thereafter Philippe de Girard patented in France important inventions for flax spinning by both dry and wet methods. His inventions, however, did not receive the promised reward and were neglected in his native country. In 1815 he was invited by the Austrian government to establish a spinning mill at Hirtenburg near Vienna, which was run with his machinery for a number of years, but it failed to prove a commercial success. In the meantime English inventors had applied themselves to the task of adapting machines to the preparation and spinning of flax. The foundation of machine spinning of flax was laid by John Kendrew and Thomas Porthouse of Darlington, who, in 1787, secured a patent for "a mill or machine upon new principles for spinning yarn from hemp, tow, flax or wool." By innumerable successive improvements and modifications, the invention of Kendrew and Porthouse developed into the perfect system of machinery with which, at the present day, spinning-mills are furnished; but progress in adapting flax fibres for mechanical spinning, and linen yarn for weaving cloth by power-loom was much slower than in the corresponding case of cotton.

Till comparatively recent times, the sole spinning implements were the spindle and distaff. The spindle, which is the fundamental apparatus in all spinning machinery, was a round stick or rod of wood about 12 in. in length, tapering towards each extremity, and having at its upper end a notch or slit into which the yarn might be caught or fixed. In general, a ring or "wheel" of stone or clay was passed round the upper part of the spindle to give it momentum and steadiness when in rotation, while in some cases an ordinary potato served the purpose of a wheel. The distaff, or rock, was a rather longer and stronger bar or stick, around one end of which, in a loose coil or ball, the fibrous material to be spun was wound. The other extremity of the distaff was carried under the left arm, or fixed in the girdle at the left side, so as to have the coil of flax in a convenient position for drawing out to form the yarn. A prepared end of yarn being fixed into the notch, the spinner, by a smart rolling motion of the spindle with the right hand against the right leg, threw it out from her, spinning in the air, while, with the left hand, she drew from the rock an additional supply of fibre which was formed in a uniform and equal strand with the right. The yarn being sufficiently twisted was released from the notch, wound around the lower part of the spindle, and again fixed in the notch at the point insufficiently twisted; and so the rotating, twisting and drawing out operations went on till the spindle was full. So persistent is an ancient and primitive art of this description that in remote districts of Scotland—a country where machine spinning has attained a high standard—spinning with rock and spindle is still practised, and yarn of extraordinary delicacy, beauty and tenacity has been spun by their agency. The first improvement on the primitive spinning labours was in the construction of the treadle-wheel, which the spindle, mounted in a frame, was fixed horizontally, and rotated by a hand passing round it and a large wheel, set in the same framework. Such a wheel became known in Europe about the middle of the 16th century, but it appears to have been in use for cotton spinning in the East from time immemorial. At a later date, which cannot be fixed, the treadle motion was attached to the spinning wheel, enabling the spinner to sit at work with both hands free; and the introduction of the two-handed or double-spindle wheel, with fliers or twisting arms on the spindles, completed the series of mechanical improvements effected on flax spinning till the end of the 18th century. The common use of the two-handed wheel throughout the rural districts of Ireland and Scotland is a matter still within the recollection of some people; but spinning wheels are now seldom seen.

The modern manufacture of linen divides itself into two branches, spinning and weaving, to which may be added the bleaching and various finishing processes, which, in the case of many linen textiles, are laborious undertakings and important branches of industry. In flax flax is received in bales or bales from the scutch mill, and after being processed into various grades, according to the quality of the material, it is labelled and placed in the store ready for the flax mill. The whole operations in yarn manufacture comprise (1) hacking, (2) preparing and (3) spinning.

Hacking. This first preparatory process consists not only in combing out, disentangling and laying smooth and parallel the separate fibres, but also serves to split up and separate into their ultimate filaments the strands of fibre, which, up to this point, have been considered as mere mass. The operation was originally performed by hand, and it was one of fundamental importance, requiring the exercise of much dexterity and judgment. The broken, ravelled and short fibres, which separate out in the process, are thrown away. In hacking, the hackle takes a "handful" or "stick" of rough flax, winds the top end around his hands, and then, spreading out the root end as broad and flat as possible, by a swinging motion dashes the fibre into the hackle box, 

The hackle box is of two or three rows of nails, which, laid lengthwise in the flax, is formed by a "wheel" or "wash" of very fine cord, of cardboard, to which is tied a "support," or board, about 8 in. in length, taper to a fine sharp point. The hackle draws his stick several times through this, working gradually from the root end to the top, and so, the fibres at the root end are sufficiently combed out and smoothed. He then seizes the root end and similarly treats the top end of the stick. The same process is again repeated on a similar tool, the length of which is about the same as the top of the middle cut and root ends. Of these the middle cut is most valuable, being uniform in length, strength and quality. The root end is more woody and harsh, while the top, though fine in quality, is uneven and variable in strength. For some flax it is required to take two cuts, in which case, the top hackle is again combed and the flax is occasionally only broken into two cuts. Flax so prepared is known as "cut line," in contradistinction to the "long line" flax, which is the fibre unbroken. The subsequent treatment of line, whether long or short, does not involve any distinct variation to require further reference to these distinctions.

The operation of hacking by machinery, the flax is first roughed and arranged in stricks, as above described under hand hacking. In the case of hackling on the spool, the rope or yarn of flax is made up into a convenient form for the modern hackling-machines. These are of two kinds: In the one, the spool is laid direct on the hackle face, and hackles have a falling and rising motion, by which the ends of the spool is laid on the hackle teeth and then moved forward one length, after which the holder takes it up, and the hackle teeth six times in travelling from end to end of the machine. The root ends being thus first hackled, the holders are shot back along an inclined plane, the iron plates unclamped, the flax reversed, and the top ends are then returned to the same hacking operation. The tow mill is used during the hackling.
process is carried down by the pins of the sheet, and is stripped from them by means of a circular brush placed immediately under the bottom roller. The brush revolves in the same direction as, but quicker than the sheet, consequently the tow is withdrawn from the sheet in a position nearly parallel to the sheet and between the roller, from which it is finally removed by a doffing knife. This material is then carded by a machine similar to, but finer than, the one described under JUTE (q.v.). The hacked flax, however, is taken direct to the preparing department.

Preparing.—The various operations in this stage have for their object the proper assortment of dressed line or qualities fit for spinning, and the drawing out of the fibres to a perfectly level and uniform continuous ribbon or sliver containing a given quantity of fibre in any given length. From the hacking the now smooth, glossy and clean striees are taken to the sorting room, where they are assorted into different qualities by the ‘line sorter,’ who arranges the linen together on the table, and from the latter the fibre. So sorted, the material is passed to the spreading and drawing frames, a series or system of machines all similar in construction and effect. The essential features of the spreading frame are:—a gradual arrangement of a series of narrow hackle bars, with short but closely cut teeth, which travel between the feed rollers and the drawing or ‘boss’ rollers, to be immediately attended to. They are, by an endless screw arrangement, carried forward at approximately the same rate at which the flax is delivered to them, and when they reach the end of the frame the hackle bars under the spreading arrange- ment are brought back to the starting-point; and thus they form an endless moving level toothed platform for conveying away the flax from the feed rollers. This is the machine in which the fibres are, for the first time, properly prepared and strengthened. In order to form this continuous sliver it is necessary that the short lengths of flax should overlap each other on the spread sheet or creeping sheet. This sheet contains four or six divisions, so that four or six slivers are produced simultaneously and are added towards the first pair of rollers—the boss rollers or retaining rollers. The fibre passes between these rollers and is immediately caught by the rising gills which carry the fibre towards the drawing rollers. The fibre on the frame is held entirely by the giving-off side of the gills, and have complete control over it, while their speed should be a little greater than the surface speed of the retaining rollers. The fibre is thus carried forward to the drawing rollers, which have a surface speed equal to the above-mentioned speed so that the difference between the speeds of the retaining and drawing rollers results in each sliver being drawn out to a corresponding degree. Finally all the slivers are run into one and in this state are passed between the delivery rollers into the sliver cans. Each can should contain the same length of sliver, a common length being 1,000 lb. A bell is automatically rung by the machine to warn the attendant that the desired length has been deposited into the can. From the spreading frame of slivers, the drawing frames, where from four to twelve slivers combined are passed through a series of over gills, and drawn out by drawing rollers to the thickness of a thread. A third and fourth similar doubling and drawing may be embraced in a preparing system, so that the number of doublings the flax will have undergone may be increased to any desired amount from one thousand to one thousand thousand, according to the quality of yarn in progress. Thus, for example, the doublings on one preparing system may be 6 × 12 × 12 × 8 = 82,944. The slivers deliver to the spinning frame are, therefore, of the thickness of 1/3,000 of an inch, and where they are singly passed through feed rollers and over gills, and, after drafting to sufficient tenacity, they are slightly twisted by ‘flyers’ and wound on bobbins, in which condition the material—termed ‘rove’ or ‘roving’—is ready for the spinning frame.

Spinning.—The spinning operation, which follows the roving, is done in two principal ways, called respectively dry spinning and wet spinning. The former is used by most manufacturers, and is the process by which the yarns, while the second is exclusively adopted in the preparation of fine yarns. The spinning frame does not differ in principle from the throstle spinning machine used in cotton manufacture. The bobbin, or ‘lop’ (the term for the end of the warp yarn, from each warp rope the spinning frame being all double) on pins in an inclined plane.

1 The preparation of tow for spinning differs in essential features from the processes above described. Tow from different sources, such as flax, hemp, jute, or cotton, at first presents a hackleable mass, of low quality and value, some being very impure, filled with woody shives, &c., while other kinds are comparatively open and clean. A preliminatory opening and cleaning is necessary for the dirty much-manufactured tow. Most modern tow is cleared by ‘breakers’ called respectively the breaker and the clearer cards till the slivers from their processes are ready for the drawing and roving frames. In the case of fine clean tows, on the other hand, passing through the spinning engine may be sufficient.

The processes which follow the carding of the hackleable material from those followed in the preparation of rove from line flax.
degrees of loss in weight. The differences in colour resulting from different degrees of bleaching are taken advantage of for producing patterns in certain classes of linen fabrics. Linen thread is prepared from the various counts of fine bleached line yarn by winding the hanks on large spools, and twisting the various strands, two, three, four or six cord as the case may be, on a doubling spindle similar in principle to the yarn spinning frame, excepting, of course, the drawing rollers. A large trade in linen thread has been created by its use in the machine manufacture of boots and shoes, saddlery and other leather goods, and in heavy sewing-machine work generally. The thread industry is largely developed at Lisburn near Belfast, at Johnstone near Glasgow, Bridport, Dorsetshire, and at Paterson, New Jersey, United States. Fine cords, net twine and ropes are also twisted from flax.

Weaving.—The difficulties in the way of power-loom linen weaving, combined with the obstinate competition of hand-loom weavers, delayed the introduction of factory wrought linen fabrics for many years after the system was fully applied to other textiles. The principal difficulty arose through the hardness and inelasticity of the linen yarns, owing to which the yarn frequently broke under the tension to which it was subjected. Competition with the hand-loom against the power-loom in certain classes of work is conceivable, although it is absolutely impossible for the work of the spinning wheel to stand against the rivalry of drawing, roving and spinning frames. To the present day, in Ireland especially, a great deal of fine weaving is done by hand-loom. Warden states that power was applied on a small scale to the weaving of canvas in London about 1812; that in 1821 power-loom were started for weaving linen at Kirkcaldy, Scotland; and that in 1824 Maberly & Co. of Aberdeen had two hundred power-loom erected for linen manufacture. The power-loom has been improved upon, and is used in the large factory, Aberdeen, which then belonged to Maberly & Co., down to the present day, and that firm may be credited with being the effective introducers of power-loom weaving in the linen trade.

The various operations connected with linen weaving, such as winding, warping, dressing, beaming and drawing-in, do not differ in essential features from the like processes in the case of cotton weaving, &c., neither is there any significant modification in the looms employed (see Weaving). Dressing is a matter of importance in the preparation of linen warps for beam. It consists in treating the spread yarn by water, slop, or farina past, and applied to it by flannel-covered rollers, the loosest of which revolves in a trough of paste. The paste is equalized on the yarn by brushes, and dried by passing the web over steam-heated cylinders before it is finally wound on the beam for weaving.

Linen fabrics are numerous in variety and widely different in their qualities, appearance and applications, ranging from heavy canvas and sail-cloth to the most delicate cambric. The natural fabrics are those which are used for a great variety of purposes, such as tent-making, towelling, covers, outer garments for men, linings, upholstery work, &c., include duck, huckaback, drain, tick, dowlas, osnaburg, and lawn and cambric. Linen is a prime class by itself, and includes principally the materials for shirts and collars and for bed sheets. Under the head of twilled linens are included drills, diapers and dimity for household use; and damask or table linen, of which two kinds are distinguished—silk or five-leaf damask, and double or eight-leaf damask, the pattern being formed by the intersection of warp and weft yarns at intervals of five and eight threads of yarn respectively. The fine linens are cambrics, lawns and handkerchiefs. Plain woven or figured and dyed linen fabrics may be assigned to a special though not important class. In a general way it may be said regarding the British industry that the heavy linen trade centres in Dundee; medium goods are made in most linen manufacturing districts; damasks are chiefly produced in Belfast, Dunfermline and Perth; and the fine linen manufactures have their seat in Belfast and the north of Ireland. Leeds and Barnsley are the centres of the linen trade in England.

Linen fabrics have several advantages over cotton, resulting principally from the microscopic structure and length of the flax fibre. The cloth is much smoother and more lustrous than cotton cloth; and, presenting a less "woolly" surface, it does not soil so readily, nor absorb and retain moisture so freely, as the more spongy cotton; and it is at once cool, clean and healthful material for bed-sheeting and clothing. Bleached linen, starched and dressed, possesses that unequalled purity, gloss and smoothness which make it alone the material suitable for shirt-fronts, collars and pocket-hand; and the gossamer delicacy, yet strength, of the thread it may be spun into fits it for the fine lace-making to which it is devoted. Flax is a slightly heavier material than cotton, while its strength is about double.

As regards the annual number of spindles and power-loom engaged in linen manufacture, the following particulars are taken from the report of the Flax Supply Association for 1905:

LINEN-PRESS, a contrivance, usually of oak, for pressing sheets, table-napkins and other linen articles, resembling a modern office copying-press. Linen presses were made chiefly in the 17th and 18th centuries, and are now chiefly interesting as curiosities of antique furniture. Usually quite plain, they were occasionally carved with characteristic Jacobean designs.

LINER, or LINE OF BATTLE SHIP, the name formerly given to a vessel considered large enough to take part in a naval battle. The practice of distinguishing between vessels fit, and those not fit, to "lie in a line of battle," arose towards the end of the 17th century. In the early 18th century all vessels of 50 guns and upwards were considered fit to lie in a line. After the Seven Years’ War (1756-63) the 50-gun ships were rejected as too small. When the great revolutionary wars broke out it was at once a line of battle ship was of 64 guns. There also came to be considered as too small, and later the line of battle-ships began with those of 74 guns. The term is now replaced by "battleship," "liner" being the colloquial name given to the great passenger ships used on the main lines of sea transport.
Ling, Per Henrik (1775–1839), Swedish medical-gymnastic practitioner, son of a minister, was born at Ljunga in the south of Sweden. His father, who had studied mathematics and Dutch literature, sent him to the University of Copenhagen to study medicine in 1797, but then went abroad for some years, first to Copenhagen, where he taught modern languages, and then to Germany, France and England. Pecuniary straits injured his health, and he suffered much from rheumatism, but he had acquired meanwhile considerable proficiency in gymnastics and fencing. In 1804 he returned to Sweden, and established himself as a teacher in these arts at Lund, being appointed in 1805 fencing-master to the university. He found that his daily exercises had completely restored his bodily health, and his thoughts now turned towards applying this experience for the benefit of others. He attended the classes on anatomy and physiology, and, through the entire curriculum for the training of a doctor; he then elaborated a system of gymnastics, divided into four branches, (1) pedagogical, (2) medical, (3) military, (4) aesthetic, which carried out his theories. After several attempts to interest the Swedish government, Ling at last in 1813 obtained their co-operation, and the Royal Gymnastic Central Institute, for the training of gymnastic instructors, was opened in Stockholm, with himself as principal and instructor. The methods were largely adapted to the larger claims made by Ling and his pupils respecting the cure of diseases—so far at least as anything more than the occasional benefit of some form of skilfully applied "massage" was concerned; but the fact that in 1831 Ling was elected a member of the Swedish Medical General Association shows that in his own country at all events his methods were regarded as consistent with professional recognition. Ling died in 1839, having previously named as the repositories of his teaching his pupils Lars Gabriel Branting (1799–1881), who succeeded him as principal of the Institute, and Karl Augustus Georgii, who became sub-director; his son, Hjalmar Ling (1820–1880), being for many years associated with them. All these, together with Major Thure Brandt, who from about 1861 specialized in the treatment of women (gynaecological gymnastics), are regarded as the pioneers of Swedish medical gymnastics.

It may be convenient to summarize here the later history of Ling's system of medical gymnastics. A Gymnastic Orthopaedic Institute was established in 1822 by Dr Nils Åkerman, and after 1837 received a government grant; and Dr Gustaf Zander elaborated a medico-mechanical system of gymnastics, known by his name, about 1857, and started his Zander Institute at Stockholm in 1865. At the Stockholm Gymnastic Central Institute qualified medical men have supervised the medical department since 1864; the course is three years (one year for qualified doctors). Broadly speaking, there have been two streams of development in the Swedish gymnastics founded on Ling's beginnings—either in a conservative direction, making certain forms of gymnastic exercises subsidiary to the prescriptions of orthodox medical science, or else in an extremely progressive direction, making these exercises a substitute for any other treatment, and claiming them as a cure for disease by themselves. Modern medical science recognizes fully the importance of properly selected exercises in preserving the body from many ailments; but the more extreme claim, which rules out the use of drugs in disease altogether, has naturally been not admitted. Modern professional disorders are divided, the representative of the more extreme section being Henrik Kjellgren (b. 1837), who has a special school and following.

Ling and his earlier assistants left no proper written account of their treatment, and most of the literature on the subject is repudiated by one set or other of the gymnastic practitioners. Dr Anders Wide, M.D., of Stockholm, has published a Handbook of Medical Gymnastics (English edition, 1899), representing the more conservative branch. Henrik Kjellgren, which covers based on Ling's, admittedly goes beyond it, is described in The Elements of Kjellgren's Manual Treatment (1903), by Edgar F. Cyriax, who before taking the M.D. degree at Edinburgh had passed out of the Stockholm Institute as a "gymnastic director." See also the encyclopaedic work on Sweden: its People and Industry (1904), p. 348, edited by G. Sundbärg for the Swedish government.

Ling 1 (Molva vulgaris), a fish of the family Gaddidae, which is readily recognized by its long body, two dorsal fins (of which the anterior is much shorter than the posterior), single long anal fin, separate caudal fin, a barb on the chin and large teeth in the lower jaw and on the palate. Its usual length is from 3 to 4 ft., but individuals of 5 or 6 ft. in length, and some 70 lb in weight, have been taken. The Ling is found in the North Atlantic, from Spitzbergen and Iceland southwards to the coast of Portugal. Its proper home is the North Sea, especially on the coasts of Norway, Denmark, Great Britain and Ireland, it occurs in great abundance, generally at some distance from the land, in depths varying between 50 and 100 fathoms. During the winter months it approaches the shores, when great numbers are caught by means of long lines. On the American side of the Atlantic it is less common, although generally distributed along the south coast of Greenland and on the banks of Newfoundland. Ling is one of the most valuable species of the cod-fish family; a certain number are consumed fresh, but by far the greater portion are prepared for exportation to various countries (Germany, Spain, Italy). They are either salted and sold as "salt-fish," or split from head to tail and dried, forming, with similarly prepared whiting. Both these quantities are consumed in Germany and elsewhere under the name of "stock-fish." The oil is frequently extracted from the liver and used by the poorer classes of the coast population for the lamp or as medicine.

Lingard, John (1771–1851), English historian, was born on the 5th of February 1771 at Winchester, where his father, of an ancient Lincolnshire peasant stock, had established himself as a carpenter. The boy's talents attracted attention, and in 1782 he was sent to the English college at Douai, where he continued until shortly after the declaration of war by England (1793). He then lived as tutor in the family of Lord Stourton, but in October 1794 he settled along with seven other former members of the old Douai college at Crook Hall near Durham, where on the completion of his theological course he became vice-president of the reorganized seminary. In 1795 he was ordained priest, and soon afterwards undertook the charge of the chairs of natural and moral philosophy. In 1808 he accompanied the community of Crook Hall to the new college at Ushaw, Durham, but in 1817 of the eleven college professors he only remained. In 1830 he retired to Maynooth, he withdrew to the secluded mission at Hornby in Lancashire, where for the rest of his life he devoted himself to literary pursuits. In 1817 he visited Rome, where he made researches in the Vatican Library. In 1821 Pope Pius VII created him doctor of divinity and of canon and civil law; and in 1825 Leo XII. is said to have made him cardinal in pecto. He died at Hornby on the 17th of July 1831.

Lingard wrote The Antiquities of the Anglo-Saxon Church (1806), of which a third and greatly enlarged addition appeared in 1815 under the title History and Antiquities of the Anglo-Saxon Church; containing an account of its origin, government, doctrines, worship, revenues, and clerical and monastic institutions; but the work with which his name is chiefly associated is A History of England from the Earliest Period to the Death of William III., which appeared originally in 8 vols. at intervals between 1819 and 1830. Three successive subsequent editions had the benefit of extensive revision by the author: a fifth edition in 10 vols. (1846–47) is the one on which the work was revised by the author by Tierney prefixed to vol. x., in 1845–55. Soon after its appearance it was translated into French, German and Italian. It is a work of ability and research; and, though Cardinal Wiseman's claim for its author that he was the only impartial historian of our country can be disregarded, the book remains interesting as representing the view taken of certain events in English history by a devout, but able and learned, Roman Catholic in the earlier part of the 19th century.

Lingayat (from linga, the emblem of Siva), the name of a peculiar sect of Siva worshippers in southern India, who call themselves Vira-Saiwas (see HINDUISM). They carry on a person a stone linga (phallus) in a silver casket. The founder of

1 As the name of the fish, "ling" is found in other Teut. languages; cf. Dutch and Ger. Leng. Norw. læng, etc. It is generally connected with "long," from the length of its body. As the name of the common heather, Calluna vulgaris (see HEATH) the word is Scandinavian; cf. Dutch and Dan. linv, Swed. lijng.
LINGAYEN—LINGUET

729

the sect is said to have been Basava, a Brahman prime minister of a Jain king in the 12th century. The Lingayats are specially numerous in the Kannarese country, and to them the Kannarese language owes its cultivation as literature. Their priests are called Jangamas. In 1901 the total number of Lingayats in all India was returned as more than 2½ millions, mostly in Mysore and the adjoining districts of Bombay, Madras and Hyderabad.

LINGAYEN, a town and the capital of the province of Pangasinán, Luzon, Philippine Islands, about 110 m. N. by W. of Manila, on the S. shore of the Gulf of Lingayen, and on a low and fertile island in the delta of the Agno river. Pop. (1903) 21,529. It has good government buildings, a fine church and plaza, the provincial high school and a girls' school conducted by Spanish Dominican friars. The climate is cool and healthy. The chief industries are the cultivation of rice (the most important crop of the surrounding country), fishing and the making of nipa-wine from the juice of the nipa palm, which grows abundantly in the neighbouring swamps. The principal language is Pangasinán; Ilocano is also spoken.

LINGEN, RALPH ROBERT WHEELER LINGEN, BARON (1819-1903), English civil servant, was born in February 1819 at Birmingham, where his father, who came of an old Hertfordshire family, with Royalist traditions, was in business. He became a scholar of Trinity College, Oxford, in 1837; won the Ireland (1838) and Hertford (1839) scholarships; and after taking his first-class in Literae Humaniores (1840), was elected a fellow of Balliol (1841). He subsequently won the Chancellor's Latin Essay (1843) and the Eldon Law scholarship (1846). After taking his degree in 1840, he became a student of Lincoln's Inn, and was called to the bar in 1847; but instead of practising as a barrister, he accepted an appointment in the Education Office, and after a short period was chosen in 1849 to succeed Sir J. Kay Shuttleworth as its secretary or chief permanent official. He retained this position till 1869. The Education Office of that day had to administer a somewhat chaotic system of government grants to local schools, and Lingen was conspicuous for his fearless discrimination and rigid economy, qualities which characterized his whole career. When Robert Lowe (Lord Sherbrooke) became, as vice-president of the council, his parliamentary chief, Lingen worked congenially with him in producing the Revised Code of 1862 which incorporated "payment by results"; but the education department encountered adverse criticism, and in 1864 the vote of censure in parliament which caused Lowe's resignation, founded (but erroneously) on an alleged "editing" of the school inspectors' reports, was inspired by a certain antagonism to Lingen's administration, but largely due to Lowe's methods. Shortly before the introduction of Forster's Education Act of 1870, he was transferred to the post of permanent secretary of the treasury. In this office, which he held till 1885, he proved a most efficient guardian of the public purse, and he was a tower of strength to successive chancellors of the exchequer. It used to be said that the best recommendation for a secretary of the treasury was to be able to say "No" so disagreeably that nobody would court a repetition. Lingen was at all events a most successful resister of importunate claims, and his undoubted talents as a financier were most prominently displayed in the direction of parsimony. In 1885 he retired. He had been made a C.B. in 1869 and a K.C.B. in 1878, and on his retirement he was created Baron Lingen. In 1889 he was made one of the first aldermen of the new London County Council, but he resigned in 1892. He died on the 22nd of July 1905. He had married in 1852, but left no issue.

LINGEN, a town in the Prussian province of Hanover, on the Ems canal, 43 m. N.N.W. of Münster by rail. Pop. 7,300. It has iron foundries, machinery factories, railway workshops and a considerable trade in cattle, and among its other industries are weaving and malting and the manufacture of cloth. Lingen was the seat of a university from 1585 to 1819.

The county of Lingen, of which this town was the capital, was united in the middle ages with the county of Trekenburg. In 1508, however, it was separated from this and was divided into an upper and lower county, but the two were united in 1541.

A little later Lingen was sold to the emperor Charles V., from whom it passed to his son, Philip II. of Spain, who ceded it in 1549 to Maurice, prince of Orange. After the death of the English king, William III., in 1702, it passed to Frederick I., king of Prussia, and in 1815 the lower county was transferred to Hanover, only to be united again with Prussia in 1866.

See Müller, Geschichte der vormaligen Grafschaft Lingen (Lingen, 1874); Herrmann, Die Erwerbung der Stadt und Grafschaft Lingen durch (Lingen, 1890); and Schricker, Geschichte des Kreises Lingen (Lingen, 1895).

LINGUET, SIMON NICHOLAS HENRI (1736-1794), French journalist and advocate, was born on the 14th of July 1736, at Reims, whither his father, the assistant principal in the Collège de Beauvais of Paris, had recently been expelled by lettre de cachet for engaging in the Jansenist controversy. He attended the Collège de Beauvais and won the three highest prizes there in 1751. He accompanied the count palatine of Zweibrücken to Poland, and on his return to Paris he devoted himself to writing. He published partial French translations of Calderon and Lope de Vega, and wrote parodies for the Opéra Comique and pamphlets in favour of the Jesuits. Received at first in the ranks of the philosophes, he soon went over to their opponents, possibly more from contempt than from conviction, the immediate occasion for his change being a quarrel with d'Alembert in 1762. He refused to be considered a philosophist, and was thus modern and enlightened, and while he delighted society with his numerous sensational pamphlets, he aroused the fear and hatred of his opponents by his stinging wit. He was admitted to the bar in 1764, and soon became one of the most famous pleaders of his century. But in spite of his brilliant ability and his record of having lost but two cases, the bitter attacks which he directed against his fellow advocates, especially against Gerbier (1725-1788), caused his dismissal from the bar in 1775. He then turned to journalism and began the Journal de politique et de littérature, which he employed for two years in literary, philosophical and legal criticisms. But a sarcastic article on the French Academy compelled him to turn over the Journal to La Harpe and seek refuge abroad. Linguet, however, continued his career of free lance, now attacking and now supporting the government, in the Annales politiques, civiles et littéraires, published from 1777 to 1792, first at London, then at Brussels and finally at Paris. Attempting to return to France in 1780 he was arrested for a caustic attack on the duc de Duras (1752-1780), an academician and marshal of France, and imprisoned nearly two years in the attache prison at Paris. In London, Brussels, and other places, for his support of the reforms of Joseph II., he was ennobled and granted an honorarium of one thousand ducats. In 1786 he was permitted by Vergennes to return to France as an Austrian counsellor of state, and to sue the duc d'Aiguillon (1730-1798), the former minister of Louis XV., for fees due him for legal services rendered some fifteen years earlier. He obtained judgment to the amount of 24,000 livres. Linguet received the support of Marie Antoinette; his fame at the time surpassed that of his rival Beaumarchais, and almost excelled that of Voltaire. Shortly afterwards he visited the emperor at Vienna to plead the case of Van der Noot and the rebels of Brabant. During the early years of the Revolution he issued several pamphlets against Mirabeau, who returned his ill-will with interest, calling him "the ignorant and bombastic M. Linguet, advocate of Neros, sultans and viziers." On his return to Paris in 1792 he defended the rights of San Domingo before the National Assembly. His last work was a defence of Louis XVI. He retired to Marnes near Ville d'Avray to escape the Terror, but was sought out and summarily condemned to death for having flattered the despots of Vienna and London." He was guillotined at Paris on the 27th of June 1793.

Linguet was a prolific writer in many fields. Examples of his attempted historical writing are Histoire du sicle d'Alexandre le Grand (Amsterdam, 1762), and Histoire impartiale des Jésuites (Madrid, 1768), the latter condemned to be burned. His opposition to the philosophes had its strongest expressions in Fauximisme des philosophes (Geneva and Paris, 1764) and Histoire des révolutions de
LINK—LINLITHGOW, MARQUESS OF

l'empire romain. (Paris, 1766-1768). His Théorie des lois civiles (London, 1867) is a vigorous defence of absolutism and attack on the politics of Montesquieu. His best legal treatise is Mémoire pour le comte de Morangles (Paris, 1772); Linguis'imprimerie in the Bastille afforded him the opportunity of writing his Mémoires sur la Bastille, first published in London in 1789; it has been translated into English (Dublin, 1783, and Edinburgh, 1884-1887), and is the best of his works though untrustworthy.

LINK. (1) Of Scandinavian origin; cf. Swed. länk, Dan. lænke; cognate with "flank," and Ger. Gelenk, joint), one of the loops of which a chain is composed; used as a measure of length in surveying, being 1/30th part of a "chain." In Gunter's chain, a "link" = 20 in.; the chain used by American engineers consists of 100 links of a foot each in length (for "link work" and "link motions" see MECHANICS: § Applied, and STEEL: § Cables). The word is still used for ships' anchors, for connecting or binding together, metaphorically or absolutely. (2) O. Eng. klinc, possibly from the root which appears in "to lean," a bank or ridge of rising ground; in Scots dialect, in the plural, applied to the ground bordering on the sea-shore, characterized by sand and coarse grass; hence for playing golf. (3) A torch made of pitch or tow formerly carried in the streets to light passengers, by men or boys called "linkboys" who plied for hire with them. Iron link-stands supporting a ring in which the link might be placed may still be seen at the doorways of old London houses. The word is of doubtful origin. It has been referred to a Med. Lat. iichinus, which occurs in the form linchicus (see Du Cange, Glossarium); this, according to a 15th-century glossary, meant a wick or match. It is an adaptation of Gr. μγιος, lamp. Another suggestion connects it with a supposed derivation of "linstock," from "lint.

The New English Dictionary thinks the likeliest suggestion is to identify the word with the "link" of a chain. The town and pitch may have been manufactured in lengths, and then cut into "links." (4) Linkoping, a city of Sweden, the seat of a bishop, and chief town of the district (län) of Östergötland. Pop. (1900) 14,552. It is situated in a fertile plain 142 m. by rail S.W. of Stockholm, and communicates with Lake Roxen (3 m. to the north) and the Göta and Kinda canals by means of the navigable Stångå. The cathedral (1150-1400), a Romanesque building with a beautiful south portal and a Gothic choir, is, next to the cathedral of Upsala, the largest church in Sweden. It contains an altar-piece by Martin Heemskerck (d. 1574), which is said to have been bought by John II. for twelve hundred measures of wheat. In the church of St Lars are some paintings by Per Horberg (1740-1810), the Swedish peasant artist. Other buildings of note are the massive episcopal palace (1470-1500), afterwards a royal palace, and the old gymnasium founded by Gustavus Adolphus in 1627, which contains the valuable library of old books and manuscripts belonging to the diocese and state college, and collection of coins and antiquities. There is also the Östergötland Museum, with an art collection. The town has manufactures of tobacco, cloth and hosiery. It is the headquarters of the second army division.

Linköping early became a place of mark, and was already a bishop's see in 828. It was at a council held in the town in 1153 that the payment of Peter's pence was agreed to at the instigation of Nicholas Breakspear, afterwards Adrian IV. The coronation of Birger Jarlsson Valdemar took place in the cathedral in 1251; and in the reign of Gustavus Vasa several important diets were held in the town. At Stångå (Stängå Bridge), close by, an obelisk (1808) commemorates the battle of Stångå (1508), when Duke Charles (Protestant) defeated the Roman Catholic Sigismund. A circle of stones in the Iron Market of Linköping marks the spot where Sigismund's adherents were beheaded in 1509.

LINLEY, THOMAS (1732-1795). English musician, was born at Wells, Somerset, and studied music at Bath, where he settled as a singing-master and conductor of the concerts. From 1774 he was engaged in the management at Drury Lane theatre, London, composing or compiling the music of many of the pieces produced there, besides songs and madrigals, which rank high among English compositions. He died in London on the 10th of November 1795. His eldest son THOMAS (1756-1778) was a remarkable violinist, and also a composer, who assisted his father; and he became a warm friend of Mozart. His works, with some of his father's, were published in two volumes, and these contain some lovely madrigals and songs. Another son, WILLIAM (1771-1835), who held a writership at Madras, was devoted to literature and music and composed glees and songs. Three daughters were similarly gifted, and were remarkable both for singing and beauty; the eldest of them ELIZABETH ANN (1754-1792), married Richard Brinsley Sheridan in 1773, and thus linked the fortunes of her family with his career.
as lieutenant-general under the duke of Hamilton, but the duke found him as difficult to work with as Leven had done previously, and his advice was mainly responsible for the defeat at Preston. After this battle he escaped to Holland. In 1650 he was allowed to return to Scotland, but in 1654 his estates were seized and he was imprisoned; he came into prominence once more at the Restoration. Callendar died on March 1674, leaving no children, and, according to a special remainder, he was succeeded in the earldom by his nephew Alexander (d. 1685), the second son of the elder earl of Linlithgow, and he again was succeeded by his nephew Alexander (d. 1692), the second son of the 3rd earl of Linlithgow. The 3rd earl’s son, James, the 4th earl, then became 5th earl of Linlithgow (see supra).

LINLITHGOW, a royal, municipal and police burgh and county town of Linlithgowshire, Scotland. Pop. (1901) 4279. It lies in a valley on the south side of a loch, 17½ m. W. of Edinburgh by the North British railway. It long preserved an ancient and picturesque appearance, with gardens running down to the lake, or climbing the lower slopes of the rising ground, but in the 19th century much of it was rebuilt. About 4 m. S. by W. lies the old village of Torphichen (pop. 540), where the Knights of St John of Jerusalem had their chief Scottish preceptor. The parish kirk is built on the site of the nave of the church of the establishment, but the ruins of the transept and of part of the choir still exist. Linlithgow belongs to the county of Lanark, but it is distant about 50 miles from Falkirk, Airdrie, Hamilton and Lanark. The industries include shoe-making, tanning and currying, manufactures of paper, glue and soap, and distilling. An old tower-like structure near the railway station is traditionally regarded as a mansion of the Knights Templar. Other public buildings are the first town house (erected in 1668 and restored in 1848 after a fire); the town hall, built in 1888; the county buildings and the burgh school, dating from the pre-Reformation period. There are some fine fountains. The Cross Well in front of the town house, a striking piece of grotesque work carved in stone, originally built in the reign of James V., was rebuilt in 1807. Another fountain is surmounted by the figure of St Michael, the patron-saint of the burgh. Linlithgow Palace is perhaps the finest ruin of its kind in Scotland. Heavy but effective, the sombre walls rise above the green knolls of the promontory which divides the lake into two nearly equal portions. In plan it is almost square (168 ft. by 174 ft.), enclosing a court (91 ft. by 88 ft.), in the centre of which stands the ruined fountain of which an exquisite copy was erected in front of Holyrood Palace by the Prince Consort. At each corner of the court was a tower, with an internal spiral staircase, and on the north-west angle being crowned by a little octagonal turret known as “Queen Margaret’s Bower,” from the tradition that it was there that the consort of James IV. watched and waited for his return from Flodden. The west side, whose massive masonry, hardly broken by a single window, is supposed to date in part from the time of James III., who later took refuge in one of its vaults from his disloyal nobles; but the larger part of the south and east side belongs to the period of James V., about 1535; and the north side was rebuilt in 1619–1620 by James VI. Of James V.’s portion, architecturally the richest, the main apartments are the Lyon chamber or parliament hall and the chapel royal. The grand entrance, approached by a drawbridge, was on the east side; above the gateway are still some weather-worn remains of rich allegorical designs. The palace was reduced to ruins by General Hawley’s dragoons, who set fire to it in 1746. Government grants have stayed further dilapidation. A few yards to the south of the palace is the church of St Michael, a Gothic (Scottish Decorated) building (16 ft. long internally excluding the apse, by 63 ft. in breadth excluding the transepts), probably founded by David I. in 1143, but mainly built by George Crichton, bishop of Dunkeld (1283–1296). The central west front steeple was till 1824 topped by a crown like that of St Giles’, Edinburgh. The chief features of the church are the embattled and pinnacled tower, with the fine doorway below, the nave, the north porch and the flamboyant window in the south transept. The church contains some fine stained glass, including a window to the memory of Sir Charles Wyville Thomson (1836–1882), the naturalist, who was born in the parish.

Linlithgow (wrongly identified with the Roman Lindum) was made a royal burgh by David I. Edward I. encamped here the night before the battle of Falkirk (1298), wintered here in 1301, and next year built "a pele [castle] in thocht and straung," which in 1313 was captured by the Scots through the assistance of William Bannock, or Binning, and his hay-cart. In 1369 the customs of Linlithgow yielded more than those of any other town in Scotland, except Edinburgh; and the burgh was taken with Lanark to supply the place of Berwick and Roxburgh in the court of the Four Burghs (1368). Robert II. granted it a charter of immunities in 1384. The palace became a favourite residence of the kings of Scotland, and often formed part of the marriage settlement of their consorts (Mary of Guelders, 1449; Margaret of Denmark, 1468; Margaret of England, 1503). James V. was born within its walls in 1512, and his daughter Mary on the 7th of December 1542. In 1570 the Regent Moray was assassinated in the High Street by James Hamilton of Bothwellhaugh. The university of Edinburgh took refuge at Linlithgow from the plague in 1645-1646; in the same year the national parliament, which had often sat in the palace, was held there for the last time. In 1661 the Covenant was publicly burned here, and in 1745 Prince Charles Edward passed through the town. In 1859 the burgh was deprived by the House of Lords of its claim to the municipal title by a court of lords, and the term Linlithgow diminished to Burghs (777) and Bowden (749).

LINLITHGOWSHIRE, or WEST LOTHIAN, a south-eastern county of Scotland, bounded N. by the Firth of Forth, E. and S.E. by Edinburghshire, S.W. by Lanarkshire and N.W. by Stirlingshire. It has an area of 76,861 acres, or 120 sq. m., and a coast line of 17 m. The surface rises very gradually from the Firth to the hilly district in the south. A few miles from the Firth a valley stretches from east to west. Between the county town and Bathgate are several hills, the chief being Knock (1017 ft.), Cairnpapple, or Cairnapple (1000), Cockleure (said to be a corruption of Cuckold-le-Roi, 912), Riccarton Hills (832) terminating eastwards in Binny Craig, a striking eminence similar to those of Stirling and Edinburgh, Torphichen Hills (777) and Bowden (749). In the coastal district a few bold rocks are found, such as Dalmeny, Dundas (well wooded and with a precipitous front), the Binns and a rounded eminence of 593 ft. named Glower-ôr-ém or Bonnytoun, bearing on its summit a monument to General Adrian Hope, who fell in the Indian Mutiny. The river Almond, rising in Lanarkshire and pursuing a north-easterly direction, enters the Firth at Crondal near Bathgate, and has a course of 18 miles during a great part of which it forms the boundary between West Lothian and Midlothian. The only water of great tributary, Breich Water, constitutes another portion of the line dividing the same counties. The Avon, rising in the detached portion of Dumbartonshire, flows eastwards across south Stirlingshire and then, following in main a northerly direction, passes the county town on the west and reaches the Firth about midway between Grangemouth and Bo’ness, having served as the boundary of Stirlingshire, during rather more than the latter half of its course. The only loch is Linlithgow Lake (102 acres), immediately adjoining the county town on the north, a favourite resort of curlers and skaters. It is 10 ft. deep at the east end and 48 ft. at the west. Eels, perch and braise (a species of roach) are abundant.

Geology.—The rocks of Linlithgowshire belong almost without exception to the Carboniferous system. At the base is the Calci- ferous Sandstone series, most of which lies between the Bathgate Hills and the eastern boundary of the county. In this series are the Calci-ferous Sandstone, a well-known limestone, 150 to 200 ft. thick in the Calci-ferous Sandstone and Carboniferous Limestone series. A peculiar serpentinite variety of the prevailing rock is quarried at Blackburn for oven floors; it is known as a "limestone." Binns Hill is the site of one of the volcanic cones of the period. The Carboniferous Limestone series consists of an upper and lower limestone group—including the Petershill, Index, Dykeneuk and Craiglenbuck limestones—and a middle group of shales, ironstones and coals; the Smithy, Easter Main, Foul, Red and Splint coals belong to this horizon. Above the Carboniferous Limestone-
LINNAEUS

Millstone grit series crops in a belt which may be traced from the mouth of the Avon southwards to Whitburn. This is followed by the true coal-measures with the Boghead or Torbanehill coal, the Coalport and Staindrop, and upper Cannell or Shotts coals of Armadale, Torbanehill and Fauldhouse. Farms between 100 and 300 acres are the most common. Turnips and potatoes are the leading green crops. Much land has been reclaimed; the parish of Linlithgow, for example, which in the beginning of the 19th century was covered with peat moors and swamp now consists of open fields. In Torphichen and Bathgate, however, patches of peat moss and swamp occur, and in the south there are extensive moors at Fauldhouse and Polkemmet. Live stock does not count for so much in West Lothian as in other Scottish counties, though a considerable number of cattle are fattened and dairy farming is followed successfully, the fresh butter and milk finding a market in Edinburgh. There is some sheep-farming, and horses and pigs are reared. The wooded land occurs principally in the parks "surrounding the many noblemen's mansions and private estates.

Other Industries. — The slate-oil trade flourishes at Bathgate, Broxburn, Armadale, Uphall, Winchburgh, Phitstock and Dalmeny. There are considerable works for glass and pottery at both Kinnell, Whitburn and Bathgate, and coal is also largely mined at these places. Coal-mining is supposed to have been conducted since Roman times, and the earliest document extant regarding coalplints in the 12th century. A charter granted about the end of the 12th century to William Oldbridge of Carriden. Fire-clay is extensively worked in connexion with the coal, and ironstone employs many hands. Limestone, freestone and whinstone are all quarried. Binny freestone was used in the building of the New College in Edinburgh, and many important buildings in Glasgow. Salmon fishing is carried on from Queensferry, and Bo'ness is the principal port.

Communications.—The North British Railway Company's line from Edinburgh to Glasgow runs across the north of the county, it controls the approaches to the Forth Bridge, and serves the rich mineral district around Alldie and Coatbridge in Lanarkshire via Bothwell to the Royal Railways Company's line from Glasgow to Edinburgh touches the extreme south of the county, construction of the Union Canal, constructed in 1818-1822 to connect Edinburgh with the Forth and Clyde Canal near Cambon in Stirlingshire, crosses the county, roughly following the N.B.R. line to Falkirk. The Union Canal, which is 31 m. long and belongs to the North British Railway, is carried across the Almond and Avon on aqueducts designed by Thomas Telford, and near Falkirk is conveyed through a tunnel 2100 ft. long.

Population and Administration. — In 1891 the population amounted to 52,868, and in 1901 to 65,708, showing an increase of 24.4% in the decennial period, the highest of any Scottish county for that decade, and a density of 547 persons to the sq. m. In 1901 300 persons spoke Gaelic only, and 575 Gaelic and English. The chief towns, with populations in 1901, are Bathgate (7549), Borrowstounness (3079), Uxbridge (7099) and Linlithgow (4279). The shire returns one member to Parliament.

Linthgowshire is part of the sheriffdom of the Lothians and Peebles, and a resident sheriff-substitute sits at Linlithgow and Bathgate. The county is under school-board jurisdiction, and there are academies at Linlithgow, Bathgate and Bo'ness. The local authorities entrust the bulk of the "residue" grant to the County Secondary Education Committee, which subsidizes elementary technical classes (cookery, laundry and dairy) and science and art and technological classes, including their equipment.

History. — Traces of the Pictish inhabitants still exist. Near Inveravon is an accumulation of shells—mostly oysters, which have long ceased to be found so far up the Forth—considered by geologists to be a natural bed, but pronounced by antiquaries to have been miden. Stone cists have been discovered at Carlowie, Dalcross, Newston and elsewhere; on Cairnmaple is a circular structure of remote date, of unknown date; and at Kipps is a cromlech that is over surrounded by stones. The wall of Antoniusinus lies for several miles strie the line. The discovery of a fine legionary tablet at Bridgeness in 1868 is held by some to be conclusive evidence that the great rampart terminated at that point and not at Carriden. Roman camps can be distinguished at several spots. On the hill of Bowden is an earthwork, which J. Stuart Glennie and others connect with the struggle of the ancient Britons against the Saxons of Northumbria. The historical associations of the county mainly cluster round the town of Linlithgow (p. 737). Kingscaul (pop. 629) disputes with Stonehouse in Lanarkshire the honour of being the birthplace of Patrick Hamilton, the martyr (1504-1528).

See Sir R. Sibbald, History of the Sherifflords of Linlithgow and Stirlingshire (Edinburgh, 1710); G. Walde, Walks along the Northern Roman Wall (Linlithgow, 1883); R. J. H. Cunningham, Geology of the Lothians (Edinburgh, 1838).

LINNAEUS, the name usually given to CARL VON LINNÉ (1707-1778), Swedish botanist, who was born on the 13th of May, O.S. (May 23, N.S.) 1707 at Råshult, in the province of Småland, Sweden, and was the eldest child of Nils Linnaeus the commissary, afterwards pastor, of the parish, and Christina Brodersson, the daughter of the previous incumbent. In 1727 he was sent to the primary school at Wexiö, and in 1734 to the gymnasium. His interests were centred on botany, and his progress in the studies considered necessary for admission to holy orders, for which he was intended, was so slight that in 1736 his father was recommended to the Duke of Brunswick to give him to a tailor or shoemaker. He was saved from this fate through Dr Rothman, a physician in the town, who expressed the belief that he would yet distinguish himself in medicine and natural history, and who further instructed him in physiology. In 1727 he entered the university of Lund, but removed in the following year to that of Upsala. There, through lack of means, he had a hard struggle until, in 1729, he made the acquaintance of Dr Olaf Celsius (1670-1756), professor of theology, at that time working at his Hierobotanicon, which saw the light nearly twenty years later. Celsius, impressed with Linnaeus's knowledge and botanical collections, and finding him necessitous, offered him board and lodging. During this period, he came upon a critique which ultimately led to the establishment of his artificial system of plant classification. This was a review of Sebastian Vaillant's Sermo de Structura Florum (Leiden, 1718), a thin quarto in French and Latin; it set him upon examining the stamens and pistils of flowers, and, becoming convinced of the paramount importance of these organs, he formed the idea of basing a system of arrangement upon them. Another work by Wallin, Tävis förlov, sive Naptiae Arborum Dissertatio (Upsala, 1730), having fallen into his hands, he drew up a short treatise on the sexes of plants, which was placed in the hands of the younger Olaf Rudbeck (1660-1740), the professor of botany in the university. In the following year Rudbeck, whose advanced age compelled him to lecture by deputy, appointed Linnaeus his adjunctus; in the spring of 1730, therefore, the latter began his lectures. The academic garden was entirely remodelled under his auspices, and furnished with many rare species. In the preceding year he had solicited appointment to the vacant post of gardener, which was refused him on the ground of his capacity for better things.

In 1732 he undertook to explore Lapland, at the cost of the Academy of Sciences of Upsala; he traversed upwards of 4600 m., and the cost of the journey is given at 5300 copper dollars, or about 525 sterling. His own account was published in English by Sir J. E. Smith, under the title Lactation Lapponica, in 1811; the scientific results were published in his Flora Lapponica (Amsterdam, 1737). In 1733 Linnaeus was engaged at Upsala in teaching the methods of examining oaks, but was prevented from delivering lectures on botany for academic reasons. At this juncture the governor of Dalecarlia invited him to travel through his province, as he had done through Lapland. Whilst on this journey, he lectured at Fahlun to large audiences; and J. Browallius (1707-1755), the chaplain there, afterwards bishop of Åbo, strongly urged him to go abroad and take his degree of M.D. at a foreign university, by which means he could afterwards settle where he pleased. Accordingly he left Sweden in 1735. Travelling by Lübeck and Hamburg,
he proceeded to Harderwijk, where he went through the requisite examinations and defended his thesis on the cause of intermittent fever. His scanty funds were now nearly spent, but he passed on through Haarlem to Leiden; there he called on Jan Fredrik Gronovius (1690–1762), who, returning the visit, was shown the Systema naturæ in MS., and was so greatly astonished at it that he set it to press at his own expense. This famous system, which, artificial as it was, substituted order for confusion, largely made its way on account of the lucid and admirable laws, and comments on them, which were issued almost at the same time (see Botany). H. Boerhaave, whom Linnaeus saw after waiting eight days for admission, recommended him to J. Burman (1707–1750), the professor of botany at Amsterdam, with whom he stayed a twelvemonth. While there he issued his Puncta Botanica, an unassuming small octavo, which exercised immense influence. For some time also he lived with the wealthy banker, G. Clifford (1685–1750), who had a magnificent garden at Hartecamp, near Haarlem.

In 1736 Linnaeus visited England. He was warmly recommended by Boerhaave to Sir Hans Sloane, who seems to have received him coldly. At Oxford Dr Thomas Shaw welcomed him cordially; J. J. Dillenius, the professor of botany, was cold at first, but afterwards changed completely, kept him a month, and even offered to share the emoluments of the chair with him. He saw Philip Miller (1690–1771), the Hortulorum Principes, at Chelsea Physic Garden, and took some plants thence to Clifford; but certain other stories which are current about his visit to England are of very doubtful authenticity.

On his return to the Netherlands he completed the printing of his Genera Plantarum, a volume which must be considered the starting-point of modern systematic botany. During the same year, 1737, he finished arranging Clifford's collection of plants, living and dried, described in the Hortus Cliffortianus. During the compilation he used to "amuse himself" with drawing up the Critica Botanica, also printed in the Netherlands. But this tremendous and unremitting labour told upon him; the atmosphere of the Low Countries seemed beyond endurance; and, resisting all Clifford's entreaties to remain with him, he started homewards, yet on the way he remained a year at Leiden, and published his Clavis Plantarum (1738). He then visited Paris, where he saw Antoine and Bernard de Jussieu, and finally sailed for Sweden from Rouen. In September 1738 he established himself as a physician in Stockholm, but, being unknown as a medical man, no one at first cared to consult him; by degrees, however, he found patients, was appointed naval physician at Stockholm, with minor appointments, and in June 1739 married Sara Morea. In 1741 he was appointed to the chair of medicine at Upsala, but soon exchanged it for that of botany. In the same year, previous to this exchange, he travelled through Öland and Gotland, by command of the state, publishing his results in Öländska och Gotländska Resa (1745). The index to this volume shows the first employment of specific names in natural history.

Henceforward his time was taken up by teaching and the preparation of other works. In 1745 he issued his Flora Suecica and Fauna Suecica, the latter having occupied his attention during fifteen years; afterwards, two volumes of observations made during journeys in Sweden, Wästra Resa (Stockholm, 1747), and Södra Resa (Stockholm, 1751). In 1748 he brought out his Hortus Upsaliensis, showing that he had added eleven hundred species to those formerly in cultivation in that garden. In 1750 his Philosophia Botanica was given to the world; it consists of a commentary on the various axioms he had published in 1735 in his Fundamenta Botanica, and was dictated to his pupil P. Löfling (1729–1756), while the professor was confined to his bed by an attack of gout. But the most important work of this period was his Species Plantarum (Stockholm, 1753), in which the specific names are fully set forth. In the same year he was created knight of the Polar Star, the first time a scientific man had been raised to that honour in Sweden. In 1755 he was invited by the king of Spain to settle in that country, with a liberal salary, and full liberty of conscience, but he declined on the ground that whatever merits he possessed should be devoted to his country's service, and Löfling was sent instead. He was enabled now to purchase the estates of Säfja and Hammarby; at the latter he built his museum of stone, to guard against loss by fire. His lectures at the university drew men from all parts of the world; the normal number of students at Upsala was five hundred, but while he occupied the chair of botany there it rose to fifteen hundred. In 1761 he was granted a patent of nobility, antedated to 1757, from which time he was styled Carl von Linné. To his great delight the tea-plant was introduced alive into Europe in 1765; in the same year his surviving son Carl (1741–1783) was allowed to assist his father in his professional duties, and to be trained as his successor. At the age of sixty his memory began to fail; an apoplectic attack in 1774 greatly weakened him; two years after he lost the use of his right side; and he died on the 10th of January 1778 at Upsala, in the cathedral of which he was buried.

With Linnaeus arrangement seems to have been a passion; he delighted in devising classifications, and not only did he systematize the three kingdoms of nature, but even drew up a treatise on the Genera Morborum. When he appeared upon the scene, new plants were discovered at an almost daily rate; and due to the increase of trading facilities; he devised schemes of arrangement by which these acquisitions might be sorted provisionally, until their natural affinities should have become clearer. Linnaeus mistook the purpose of homonymous species, first enunciated the principles for defining genera and species, and his uniform use of specific names, is enduring. His style is terse and laconic; he methodically treated each organ in its proper turn, and had a special term for each, the meaning of which did not vary. The reader cannot doubt the author's intention; his sentences are business-like and to the point. The omission of the verb in his descriptions was an innovation, and gave an abruptness to his treatment of the subject which was foreign to the writing of his time; but it probably by its succinctness added to the popularity of his works.

No modern naturalist has impressed his own character with greater force upon his pupils than old Linnaeus. He imbued them with the love of natural history acquired in an atmosphere of enthusiasm, trained them to close and accurate observation, and then despatched them to various parts of the globe.

His published works amount to more than one hundred and eleven volumes, including the Auctornites Academicae, for which he provided the material, revising them also for press; corrections in his handwriting may be seen in the Banksian and Linnean Society's libraries. Many of his works were not published during his lifetime; those which were enumerated by Dr Richard Pulteney in his General View of the Writings of Linnaeus (1781). His widow sold his collections and books to Sir J. E. Smith, the first president of the Linnean Society of London. When Smith died in 1828, a subscription was raised to purchase the Linnaean Society's library, which property they became. The manuscripts of many of Linnaeus's publications, and the letters he received from his contemporaries, also came into the possession of the Society.

(B. D. J.)

LINNELL, JOHN (1792–1883), English painter, was born in London on the 16th of June 1792. His father being a carver and gilder, Linnell was early brought into contact with artists, and when he was ten years old he was drawing and selling his portraits in chalk and pencil. His first artistic instruction was from Benjamin West, and he spent a year in the house of John Varley the elder. In 1803 he was put in the house of John Varley the younger, and in 1805 he was put to work by William Hunt and Mulready as fellow-pupils, and made the acquaintance of Shelley, Godwin and other men of mark. In 1805 he was admitted a student of the Royal Academy, where he obtained medals for drawing, modelling and sculpture. He was also trained as an engraver, and executed a transcript of Varley's 'Burial of Saul.' In after life he frequently occupied himself with the burin, publishing, in 1834, a series of outlines from Michelangelo's frescoes in the Sistine chapel, and, in 1840, superintending the issue of a selection of plates from the pictures in Buckingham Palace, one of them, a Titian landscape, being mezzotinted by himself. At first he supported himself mainly by miniature painting, and by the execution of larger portraits, such as the likenesses of Mulready, Whately, Peel and Carlyle. Several of his portraits he engraved with his own hand in line and mezzotint. He also painted many subjects like the 'St John Preaching,' the 'Covenant of Abraham,' and the 'Journey to Emmaus,' in which, while the line'scape is usually prominent the figures are yet of sufficient importance to supply the title.
of the work. But it is mainly in connexion with his paintings of peculiar landscape that his name is known. His works commonly deal with some scene of typical uneventful English landscape, which is made impressive by a gorgeous effect of sunrise or sunset. They are full of true poetic feeling, and are rich and glowing in colour. Linnell was able to command very large prices for his pictures, and about 1850 he purchased a property at Redhill, Surrey, where he resided till his death on the 20th of January 1882, painting with unabated power till within the last few years of his life. His leisure was greatly occupied with a study of the Scriptures in the original, and he published several pamphlets and larger treatises of Biblical criticism. Linnell was one of the best friends and kindest patrons of William Blake. He gave him the two largest commissions he ever received for single series of designs—£150 for drawings and engravings of *The Inventions to the Book of Job*, and a like sum for those illustrative of Dante.

**LINNET.** O. Eng. Linette and Linet-wige, whence seems to have been corrupted the old Scottish "Lintquhit," and the modern northern English "Lintwhite," originally a somewhat generalized bird-name, applied particularly for the *Fringilla cannabina* of Linnaeus, the *Linota cannabina* of recent ornithologists. This is a common song-bird, frequenting almost the whole of Europe south of lat. 60°, and in Asia extending to Turkestan. It is known as a winter visitor to Egypt and Abyssinia, and is abundant at all seasons in Barbary, as well as in the Canaries and Madeira. Though the fondness of this species for the seeds of *Flax* (Linum) and hemp (*Cannabis*) has given it its common name in so many European languages, it feeds largely, if not chiefly in Britain on the seeds of plants of the order *Compositae*, especially those growing on heaths and commons. As these waste places have been gradually brought under the plough, in England and Scotland particularly, the haunts and means of subsistence of the linnet have been curtailed, and hence its numbers have undergone a very visible diminution throughout Great Britain. According to its sex, or the season of the year, it is known as the red, grey or brown linnet, and by the earlier English writers on birds, as well as in many localities at the present time, these names have been held to distinguish at least two species; but there is now no question among ornithologists on this point, though the conditions under which the bright crimson-red colouring of the breast and crown of the cock's spring and summer plumage is donned and doffed may still be open to discussion. Its intensity seems due, however, in some degree at least, to the weathering of the brown fringes of the feathers which hide the more brilliant hue, and in the Atlantic islands examples are said to retain their gay tints all the year round, while throughout Europe there is scarcely a trace of them visible in autumn and winter; but, beginning to appear in spring, they reach their greatest brilliancy towards midsummer; they are never assumed by examples in confinement. The linnet begins to breed in April, the nest being generally placed in a bush at no great distance from the ground. It is always a neatly composed of fine twigs, roots or bents, and lined with wool or hair. The eggs, often six in number, are of a very pale blue marked with reddish or purplish brown. Two broods seem to be common in the course of the season, and towards the end of summer the birds—the young greatly preponderating in number—collect in large flocks and move to the sea-coast, whence a large proportion depart for more southern latitudes. Of these emigrants some return the following spring, and are recognizable by the more advanced state of their plumage, the effect presumably of having wintered in countries enjoying a brighter and hotter sun.

Nearly allied to the foregoing species is the twite, so named from its ordinary call-note, or mountain-linet, the *Linota flavirostris*, or *L. montium* of ornithologists, which can be distinguished by its yellow bill, longer tail and reddish-tawny throat. This bird never assumes any crimson on the crown or breast, but the male has the rump at all times tinged more or

name of "flax." In 1864, owing to the serious aspect of the prevalent adulteration, a union of traders was formed under the name of the "Linseed Association." This body samples all linseed oil arriving in England and reports on its value.

Linseed oil, the most valuable drying oil, is obtained by expression from the seeds, with or without the aid of heat. Preliminary to the operation of pressing, the seeds are crushed and ground to a fine meal. Cold pressing of the seeds yields a golden-yellow oil; that obtained by heating the crushed seeds to 160 °F. (71 °C), and then expressing the oil. So obtained, it is somewhat turbid and yellowish-brown in colour. On storing, moisture and mucilaginous matters gradually settle off, and the pure oil is obtained by decanting, and is known as "tanked oil," and has a high value in varnish-making. The delay attendant on this method of purification is avoided by treating the crude oil with 1 to 2% of a somewhat strong sulphuric acid, which eluates from the oil the ashes and waters of the impurities. For the preparation of "artist's oil," the finest form of linseed oil, the refined oil is placed in shallow trays covered with glass, and exposed to the action of the sun's rays. Numerous other methods of purification, some based on the oxidizing action of ozone, have been suggested.

The yield of oil from different classes of seed varies, but from 23 to 28% of the weight of the seed operated upon should be obtained. A good average quality of seed weighing about 932 lb per quarter has been reported as giving out 874 lb of oil.

Commercial linseed oil has a peculiar, rather disagreeable sharp taste and smell; its specific gravity is given as varying from 0.928 to 0.953, and it solidifies at about 27°. By saponification it yields a neutral linolein, linseed oil, oleic oil, linoleic oil, andisolinolein. Exposed to the air in thin films, linseed oil absorbs oxygen and forms "linoxyx," a resinous semi-elastic, caoutchouclike mass, of uncertain composition. The oil, when boiled with sodium carbonate, and also when agitated with a soap, the process of resublimation in the air with greatly increased rapidity.

Its most important use is in the preparation of oil paints and varnishes. By painters both raw and boiled oil are used, the latter form being employed more particularly in the medium and varnish. Linseed oil is used separately as the basis of all varnishes. Boiled oil is prepared in a variety of ways—that most common being by heating the raw oil in an iron or copper boiler, which, to allow for frothing, must only be a few inches deep. The oil is heated in the kettle, and the oil is brought gradually to the point of ebullition, at which it is maintained for two hours, during which time moisture is driven off, and the scum and froth which accumulate on the surface are ladled off. When the degree of purity desired is obtained—usually equal weights of lard and fish mince being used to the extent of 3% of the charge of oil; and these a small proportion of the oil is generally thrown in. After the addition of the lard and fish, the oil is kept for two or three hours; the fire is then suddenly withdrawn, and the oil is left covered up in the boiler for ten hours or more. Before selling out, it is usually stored in settling tanks for a few weeks, during which time the undecomposed oil is allowed to settle at the bottom and is then removed. Besides the dryness and insolubility of the mentioned, lead acetate, manganese borate, manganese dioxide, zinc sulphate and other bodies are used.

Linseed oil is also the principal ingredient in printing and lithographic inks, and the process is prepared by heating it in an iron pot up to the point where it either takes fire spontaneously or can be ignited with any flaming substance. After the oil has been allowed to burn for some time according to the convenience of the varnish desired, the pot is covered over, and the product when cooled forms a viscous tenacious substance which in its most concentrated form may be drawn into threads. By boiling this varnish with dilute nitric acid vapours of acrolein are given off, and the oil is gradually converted into a solid body which is massed the same as the ultimate oxidation product of both raw and boiled oil.

Linseed oil is subject to various falsifications, chiefly through the addition of cotton-seed, sunflower-seed and hemp-seed oils; and rape oil and mineral oils also are not infrequently added. Except by smell, by change of specific gravity, and by deterioration of drying properties, these adulterations are difficult to detect.

Linstock (adapted from the Dutch linstok, i.e. "match-stick," from lont, a match, skôk, a stick; the word is sometimes erroneously spelled "lintstick" from a supposed derivation from "lint" in the sense of tinder), a kind of torch made of a stick of a third length to a foot at each end to hold a lighted match, and a point on the other end is the ground. "Linstock" were used for discharging cannon in the early days of artillery.

Lint (in M. Eng. linnet, probably through Fr. linette, from lin, the flax-plant; cf. "line"); properly the flax-plant, now only in Scots dialect; hence the application of such expressions as "lint-haired," "lint white locks" to flaxen hair. It is also the term applied to the flax when prepared for spinning, and to the waste material left over which was used for tinder. "Lint" is still the name given to a specially prepared material for dressing wounds, made soft and fluffy by scarring or waving linen cloth.

Lintel (O. Fr. lintel, mod. linteu, from Late Lat. linitium, limes, boundary, confused in sense with limen, threshold; the Latin name is supericium, Ital. soprasogli, and Ger. Sturz), in architecture, a horizontal piece of stone or timber over a doorway or opening, provided to carry the superstructure. In order to relieve the lintel from too great a pressure a "discharging arch" is generally built over it.

Linth, or Limmat, a river of Switzerland, one of the tributaries of the Aar. It rises in the glaciers of the Tödi range, and has cut out a deep bed which forms the Grossthal that comprises the greater portion of the canton of Glarus. A little below the town of Glarus the river, keeping its northerly direction, encounters the alluvial plain which it has formed, towards the Walensee and the Lake of Zürich. But between the Lake of Zürich and the Walensee the huge desolate alluvial plain grew ever in size, while great damage was done by the river, which overflowed its bed and the dykes built to protect the region near it. The Swiss diet decided in 1804 to undertake the "correction" of this turbulent stream. The necessary works were begun in 1807 under the supervision of Hans Conrad Escher of Zürich (1767-1823). The first portion of the undertaking was completed in 1811, and received the name of the "Escher canal," the river being thus diverted into the Walensee. The second portion, known as the "Linth canal," regulated the course of the river between the Walensee and the Lake of Zürich and was completed in 1816. Many improvements and extra protective works were carried out after 1816, and it was estimated that the total cost of this great engineering undertaking from 1807 to 1902 amounted to about £200,000, the date for the completion of the work being 1846. In commemoration of the efforts of Escher, the Swiss diet in 1823 (after his death) decided that his male descendants should bear the name of "Escher von der Linth." On issuing from the Lake of Zürich the Linth alters its name to that of "Limmat," it does not appear wherefore, and, keeping the north-westerly direction it had taken from the Walensee, joins the Aar a little way below Brugg, and just below the junction of the Reuss with the Aar. (W. A. B. C.)

Linton, Eliza Lynn (1822-1898), English novelist, daughter of the Rev. J. Lynn, vicar of Crosthwaite, in Cumberland, was born at Keswick on the 10th of February 1822. She early manifested great independence of character, and, in great measure educated herself from the stores of her father's library. Coming to London about 1845 with a large stock of miscellaneous erudition, she turned this to account in her first novels, Azeth the Egyptian (1846) and Amymone (1848), a romance of the days of Pericles. Her next story, Reality, in the field of modern life (1851), was not successful, and for several years she seemed to have abandoned fiction. When, in 1865, she reappeared with Grace your Nettle, it was as an expert in a new style of novel-writing—stirring, fluent, ably-constructed stories, retaining the attention throughout, but affording little to reflect upon or to remember. Measured by their immediate success, they gave her an honourable position among the writers of her day, and secure of an audience, she continued to write with vigour nearly until her death. Lizzie Lorton of Greyrigg (1866), Patricia Kemball (1874), The Atonement of Leam Dundas (1877) are among the best examples of this more mechanical side of her talent, to which there were notable exceptions in Joshua Davidson (1872), a bold but not irreverent adaptation of the story of the Carpenter of Nazareth to that of the French Commune; and Christopher Kirkwood, a veiled autobiography (1873). Mrs Linton was a practised and constant writer in the journals of the day; her articles on the "Girl of the Period" in the Saturday Review produced a great sensation, and she was a constant contributor to the St James's Gazette, the Daily News and other leading newspapers. Many of her detached essays have been collected. In 1858 she married W. J. Linton, the engraver, but the union was
soon terminated by mutual consent; she nevertheless brought up one of Mr Linton’s daughters by a former marriage. A few years before her death she retired to Malvern. She died in London on the 14th of July 1868.

Her reminiscences appeared after her death under the title of My Literary Life (1899) and her life has been written by G. S. Layard (1901).

LINTON, WILLIAM JAMES (1812-1897), English wood-engraver, republican, and author, was born in London. He was educated at Stratford, and in his sixteenth year was apprenticed to the wood-engraver G. W. Bonner. His earliest known work is to be found in Martin and Westall’s Pictorial Illustrations of the Bible (1833). He rapidly rose to a place amongst the foremost wood-engravers of the time. After working as a journeyman engraver with two or three firms, losing his money over a cheap political library called the “National,” and writing a life of Thomas Paine, he went into partnership (1842) with John Orrin Smith.

The firm was immediately employed on the Illustrated London News, just then projected. The following year Orrin Smith died, and Linton, who had married a sister of Thomas Wade, editor of Bell’s Weekly Messenger, found himself in sole charge of a business upon which two families were dependent.

For years he had concerned himself with the social and European political problems of the time, and was now actively engaged in the republican propaganda. In 1844 he took a prominent part in exposing the violation by the English post-office of Mazzini’s correspondence. This led to a friendship with the Italian revolutionist, and Linton threw himself with ardour into European politics. He carried the first congratulatory address of English workmen to the French Provisional Government in 1848. He edited a twopenny weekly paper, The Cause of the People, published in the Isle of Man, and he wrote political verses for the Dublin Nation, signed “Spartacus.” He helped to found the “International League” of patriots, and, in 1850, with G. H. Lewes and Thornton Hunt, started The Leader, an organ which, however, did not satisfy his advanced republicanism, and from which he soon withdrew. The same year he wrote a series of articles propounding the views of Mazzini in The Red Republican.

In 1852 he took up his residence at Brantwood, which he afterwards sold to John Ruskin, and from there issued The English Republican, first in the form of weekly tracts and afterwards as a monthly magazine—“a useful exponent of republican principles, a faithful record of republican progress throughout the world; an organ of propaganda and a medium of communication for the active republicans in England.” Most of the paper, which never paid its way and was abandoned in 1855, was written by himself. In 1852 he also printed for private circulation an anonymous volume of poems entitled The Plaint of Freedom. After the failure of his paper he returned to his proper work of wood-engraving. In 1857 his wife died, and in the following year he married Eliza Lynn (afterwards known as Mrs Lynn Linton) and returned to London. In 1864 he retired to Brantwood, his wife remaining in London. In 1867, probably by force of circumstances, he determined to try his fortune in America, and finally separated from his wife, with whom, however, he always corresponded affectionately. With his children he settled at Applecore, New Haven, Connecticut, where he set up a printing-press. Here he wrote Practical Hints on Wood-Engraving (1879), James Watson, a Memoir of Chartist Times (1879), A History of Wood-Engraving in America (1882), Wood-Engraving, a Manual of Instruction (1884), The Masters of Wood-Engraving, for which he made two journeys to England (1890), The Life of Whittier (1893), and Memories, an autobiography (1895). He died at New Haven on the 29th of December 1897. Linton was a singularly gifted man, who, in the words of his wife, if he had not bitten the Dead Sea apple of impracticable politics, would have risen higher in the world of both art and letters. As an engraver on wood he reached the highest point of execution in his own line. He carried on the tradition of Bewick, sought for intelligent as against merely manipulative excellence in the use of the graver, and championed the use of the “white line” as well as of the black, believing with Ruskin that the former was the truer and more telling basis of aesthetic expression in the wood-block printed upon paper.

See W. J. Linton, Memories; F. G. Kitton, article on “Linton” in English Illustrated Magazine (April 1891); G. S. Layard, Life of Mrs Lynn Linton (1901).

LINTOT, BARNABY BERNARD (1675-1726), English publisher, was born at Southwater, Sussex, on the 1st of December 1675, and started business as a publisher in London about 1698. He published for many of the leading writers of the day, notably Vanbrugh, Steele, Gay and Pope. The latter’s Rape of the Lock in its original form was first published in Lintot’s Miscellany, and Lintot subsequently issued Pope’s translation of the Iliad and the joint translation of the Odyssey by Pope, Fenton and Broome. Pope quarrelled with Lintot with regard to the supply of free copies of the latter translation to the author’s subscribers, and in 1728 satirized him in the Dunciad, and in 1755 in the Prologue to the Satires, though he does not appear to have had any serious grievance. Lintot died on the 3rd of February 1736.

LINUS, one of the saints of the Gregorian canon, whose festival is celebrated on the 23rd of September. All that can be said with certainty about him is that his name appears at the head of all the lists of the bishops of Rome. Irenaeus (Adv. Haer. iii. 3. 3) identified him with the Linus mentioned by St Paul in 2 Tim. iv. 21. According to the Liber Pontificalis, Linus suffered martyrdom, and was buried in the Vatican. In the 17th century an inscription was found near the confession of St Peter, which was believed to contain the name Linus; but it is not certain that this epitaph has been read correctly or completely. The apocryphal Latin account of the death of the apostles Peter and Paul is falsely attributed to Linus.

See Acta Sanctorum, September, vi. 539-545; C. de Smidt, Dictionnaire, selectione etat hist. eccl. pp. 300-512 (Ghent, 1876); L. Duchesne’s edition of the Liber Pontificalis, i. 127 (Paris, 1886); R. A. Lipsius, Die apokryphen Apostelgeschichten, ii. 85-96 (Brunswick, 1883-1890); J. B. de Rossi, Bullettino di arch. cristiana, new series, v. 291 (1879).

LINUS, one of a numerous class of heroic figures in Greek legend, of which several examples are found in Hyacinthus and Adonis. The connected legend is always of the same character: a beautiful youth, fond of hunting and rural life, the favourite of some god or goddess, suddenly perishes by a terrible death. In many cases the religious background of the legend is preserved by the annual ceremonial that commemorated it. At Argos this religious character of the Linus myth was best preserved: the secret child of Psamthe by the god Apollo, Linus is exposed, nursed by sheep and torn in pieces by sheep-dogs. Every year at the festival Arnis or Cynophontis, the women of Argos mourned for Linus and propitiated Apollo, who in revenge for his child’s death had sent a female monster (Poinè), which tore the children from their mothers’ arms. Lambs were sacrificed, all dogs found running loose were killed, and women and children raised a lament for Linus and Psamthe (Pausanias i. 43. 7; Conan, Narrat. 19). In the Theban version, Linus, the son of Amphimarus and the muse Urania, was a famous musician, inventor of the Linus song, who was said to have been slain by Apollo, because he had challenged him to a contest (Pausanias ix. 29. 6). A later story makes him the teacher of Heracles, by whom he was killed because he had rebuked his pupil for stupidity (Apollo-Po. ii. 4. 9). On Mount Helicon there was a grotto containing his statue, to which sacrifice was offered every year before the sacrifices to the Muses. From being the inventor of musical methods, he was finally transformed by later writers into a composer of prophecies and legends. He was also said to have adapted the Phoenician letters introduced by Cadmus to the Greek language. It is generally agreed that Linus and Ailinus are of Semitic origin, derived from the words of lanu (woe to us), which formed the burden of the Adonis and similar songs popular in the East. The Linus song is mentioned in Homer; the tragedies often use the word aLanos as the refrain in mournful songs, and Euripides calls the custom a Phrygian one. Linus, originally, the personification of the song of lamentation, becomes, like Adonis, Maneros, Narcissus, the representative
of the tender life of nature and of the vegetation destroyed by the fiery heat of the dog-star.

The chief work on the subject is H. Brugsch, Die Adonisklage und das Linosied (1852); see also article in Roscher’s Lexikon der Mythologie; J. G. Frazer, Golden Bough (ii. 224, 253), where, the identity of Linus with Adonis (possibly a corn-spirit) being assumed, the lament is explained as the lamentation of the reapers over the dead corn-spirit; W. Mannhardt, Wald- und Feldsclute, ii. 281.

LINZ, capital of the Austrian duchy and crownland of Upper Austria, and see of a bishop, 117 m. W. of Vienna by rail. Pop. (1900) 58,778. It lies on the right bank of the Danube and is connected by an iron bridge, 308 yds. long, with the market-town of Urfahr (pop. 12,827) on the opposite bank. Linz possesses two cathedrals, one built in 1669–1682 in rococo style, and another in early Gothic style, begun in 1682. In the Capuchin church is the tomb of Count Raimonlino Montecuccoli, who died at Linz in 1680. The museum Francisco-Carolinum, founded in 1833 and reconstructed in 1895, contains several important collections relating to the history of Upper Austria. In the Franz Josef-Platz stands a marble monument, known as Trinity Column, erected by the emperor Charles VI. in 1723, commemorating the triple deliverance of Linz from war, fire, and pestilence. The principal manufactories are of tobacco, boat-building, agricultural implements, foundries and cloth factories. Being an important railway junction and a port of the Danube, Linz has a very active transit trade.

Linz is believed to stand on the site of the Roman station Lentia. The name of Linz appears in documents for the first time in 799 and it received municipal rights in 1324. In 1490 it became the capital of the province above the Enns. It successfully resisted the attacks of the insurgent peasants under Stephen Fadinger on the 21st and 22nd of July 1626, but its suburbs were laid in ashes. During the siege of Vienna in 1683, the castle of Linz was the residence of Leopold I. In 1741, during the War of the Austrian Succession, Linz was taken by the Bavarians, but was recovered by the Austrians in the following year. The bishopric was established in 1784.

See F. Krackowitzer, Die Donaubrund Linz (Linz, 1901).

LION (Lat. leo, leonis; Gr. λέων). From the earliest historic times few animals have been better known to man than the lion. Its history is made up of the history of the race of Man, for civilization took its origin. The literature of the ancient Hebrews abounds in allusions to the lion; and the almost incredible numbers stated to have been provided for exhibition and destruction in the Roman amphitheatres (as many as six hundred on a single occasion by Pompey, for example) show how abundant these animals must have been within accessible distance of Rome.

Even within the historic period the geographical range of the lion covered the whole of Africa, the south of Asia, including Syria, Arabia, Asia Minor, Persia and the greater part of northern and central India. Professor A. B. Meyer, director of the zoological museum at Dresden, has published an article on the alleged existence of the lion in historical times in Greece, a translation of which appears in the Report of the Smithsonian Institution for 1905. Meyer is of opinion that the writer of the Hliad was probably acquainted with the lion, but this does not prove its former existence in Greece. The accounts given by Herodotus and Aristotle merely go to show that about 500 B.C. lions existed in some part of eastern Europe. The Greek name for the lion is very ancient, and this suggests, although by no means demonstrates, that it refers to an animal indigenous to the home of the race. It is probable that lions did exist in Greece at the time of Herodotus; and it is quite possible that the representation of a lion-chase incised on a Mycenean dagger may have been taken from life. In prehistoric times the lion was spread over the greater part of Europe; and if, as is very probable, the so-called Felis atrox be inseparable, its range also included the greater part of North America.

At the present day the lion is found throughout Africa (save in places where it has been exterminated by man) and in Meso-potamia, Persia, and some parts of north-west India. According to Dr W. T. Blanford, lions are still numerous in the reedy swamps, bordering the Tigris and Euphrates, and also occur on the west flanks of the Zagros mountains and the oak-clad ranges near Shiraz, to which they are attracted by the herds of swine which feed on the acorns. The lion nowhere exists in the table-land of Persia, nor is it found in Balthushtan. In India it is confined to the province of Kathiawar in Gujarat, though within the 19th century it extended through the north-west parts of Hindustan, from Bahawalpur and Sond to at least the Jumna (about Delhi) southward as far as Khândesh, and in central India through the Sagur and Narbuda territories, Bundelkund, and as far east as Palamau. It was extirpated in Harihâna about 1824. One was killed at Rhyli, in the Dumnaoh district, Sagur and Narbuda territories, so late as in the cold season of 1847–1848; and about the same time a few still remained in the valley of the Sind river in Kotah, central India.

The variations in external characters which lions present, especially in the colour and the amount of mane, as well as in the general colour of the fur, indicate local races, to which special names have been given; the Indian lion being F. leo gujratensis. It is noteworthy, however, that, according to Mr F. C. Selous, in South Africa the black-maned lion and others with yellow scantly manes are found, not only in the same locality, but even among individuals of the same parentage.

The lion belongs to the genus Felis of Linneaus (for the characters and position of which see Carnivora), and differs from the tiger and leopard in its uniform colouring, and from all the other Felidae in the hair of the top of the head, chin and neck, as far back as the shoulder, being not only much longer, but also differently disposed from the hair elsewhere, being erect or directed forwards, and so constituting the characteristic ornament called the mane. There is also a tuft of elongated hairs at the end of the tail, one upon each elbow, and in most lions a copious fringe along the middle line of the under surface of the body, wanting, however, in some examples. These characters are, however, peculiar to the adults of the male sex; and even as regards coloration young lions show indications of the darker stripes and mottings so characteristic of the greater number of the members of the genus. The usual colour of the adult is yellowish-brown, but it may vary from a deep red or chestnut brown to an almost silvery grey. The mane, as well as the long hair of the other parts of the body, sometimes scarcely differs from the general colour, but is usually darker and not
unfrequently nearly black. The mane begins to grow when the animal is about three years old, and is fully developed at five or six.

In size the lion is only equalled or exceeded by the tiger among existing Felidae; and though both species present great variations, the largest specimens of the latter appear to surpass the largest lions. A full-sized South African lion, according to Selous, measures slightly less than 10 ft. from nose to tip of tail, following the curves of the body. Sir Cornelius Harris gives 10 ft. 6 in., of which the tail occupies 3 ft. The lioness is about a foot less.

The internal structure of the lion, except in slight details, resembles that of other Felidae, the whole organization being that of an animal adapted for an active, predatory existence. The teeth especially exemplify the carnivorous type in its highest condition of development. The most important function they have to perform, that of seizing and holding firmly animals of considerable size and strength, violently struggling for life, is provided for by the great, sharp-pointed and sharp-edged canines, placed wide apart at the angles of the mouth, the incisors between them being greatly reduced in size and kept back nearly to the same level, so as not to interfere with their action. The jaws are short and strong, and the depth of the zygomatic arches, and great development of the bony ridges on the skull, give ample space for the attachment of the powerful muscles by which they are closed. In the cheek-teeth the sectorial or opposed-tooth cutting function is developed at the expense of the tubercular or grinding, there being only one rudimentary tooth of the latter form in the upper jaw, and none in the lower. They are, however, sufficiently strong to break bones of large size. The tongue is long and flat, and remarkable for the development of the papillae of the anterior part of the dorsal surface, which (except near the edge) are modified so as to resemble long, compressed, recurved, horny spines or claws, which, near the middle line, attain the length of one-fifth of an inch. They give the part of the tongue on which they occur the appearance and feel of a coarse rasp. The feet are furnished with round soft pads or cushions covered with thick, naked skin, one on the under surface of each of the principal toes, and one larger one of trihobed form, behind these, under the lower ends of the metacarpal and metatarsal bones, which are placed nearly vertically in ordinary progression. The claws are large, strongly compressed, sharp, and exhibit the retractive condition in the highest degree, being drawn backwards and upwards into a sheath by the action of an elastic ligament so long as the foot is in a state of repose, but exerted by muscular action when the animal strikes its prey.

The lion lives chiefly in sandy plains and rocky places interspersed with dense thorn-thickets, or frequents the low bushes and tall rank grass and reeds that grow along the sides of streams and near the springs where it lies in wait for the larger herbivorous animals on which it feeds. Although occasionally seen abroad during the day, especially in wild and desolate regions, where it is subject to little molestation, the night is, as in the case of so many other predaceous animals, the period of its greatest activity. It is then that its characteristic roar is chiefly heard, as thus graphically described by Gordon-Cumming:

"One of the most striking things connected with the lion is his voice, which is extremely grand and peculiarly striking. It consists at times of a low deep moan, repeated five or six times, ending in faintly audible sighs; at other times he startles the forest with loud, deep-toned, solemn roars, repeated in quick succession, each increasing in loudness to the third or fourth, when his voice dies away in five or six low muffled sounds very much resembling distant thunder. At times, and not unfrequently, a troop may be heard, roaring in concert, one assuming the lead, and two, three, or four more regularly taking up their parts, like persons singing a catch. Like our Scottish staggs at the rutting season, they roar loudest in cold frosty nights; but on no occasions are their voices to be heard altogether in such perfection, or by so intensly strong a vocalist when two or three troops of strange lions approach a fountain to drink at the same time. When this occurs, every member of each troop sounds a bold roar of defiance at the opposite parties; and when one roar, all roar together, and each seems to vie with his comrades in the intensity and power of his voice. The power and grandeur of these nocturnal concerts is inconceivably striking and pleasing to the hunter's ear."

"The usual pace of a lion," C. J. Anderson says, "is a walk, and, though apparently rather slow, yet, from the great length of his body, he is able to get over a good deal of ground in a short time. Occasionally he trots, when his speed is not considerable. His gallop—or rather succession of bounds—is, for a short distance, very fast—nearly or quite equal to that of a horse."

The lion, as with other members of the feline family, the same writer says, "seldom attacks his prey openly, unless compelled by extreme hunger. For the most part he steals upon it in the manner of a cat, or ambushes himself near to the water or a pathway frequented by game. At such times he lies crouched upon his belly in a thicket until the animal approaches sufficiently near, when, with one prodigious bound, he pounces upon it. In most cases he is successful, but should his intended victim escape, as at times happens, from his having miscalculated the distance, he may make a second or even a third bound, which, however, usually prove fruitless, or he returns disconcerted to his hiding-place, there to wait for another opportunity." His food consists of all the larger herbivorous animals of the country in which he resides—buffaloes, antelopes, zebras, giraffes or even young elephants or rhinoceroses. In cultivated districts cattle, sheep, and even human inhabitants are never safe from his nocturnal ravages. He appears, however, as a general rule, only to kill when hungry or attacked, and not for the mere pleasure of killing, as with some other carnivorous animals. He, moreover, by no means limits himself to animals of his own killing, but, according to Selous, often prefers eating game that has been killed by man, even when not very fresh, to taking the trouble to catch an animal himself.

The lion appears to be monogamous, a single male and female continuing attached to each other irrespectively of the pairing season. At all events the lion remains with the lioness while the cubs are young and helpless, and assists in providing her and them with food, and in educating them in the art of providing for themselves. The number of cubs at a birth is from two to four, usually three. They are said to remain with their parents till they are about three years old.

Though not strictly gregarious, lions appear to be sociable towards their own species, and often are found in small troops sometimes consisting of a pair of old ones with their nearly full grown cubs, but occasionally of adults of the same sex; and there seems to be evidence that several lions will associate for the purpose of hunting upon a preconcerted plan. Their natural ferocity and powerful armature are sometimes turned upon one another; combats, often mortal, occur among male lions under the influence of jealousy; and Anderson relates an instance of a quarrel between a hungry lion and lioness over the carcass of an antelope which they had just killed, and which did not seem sufficient for the appetite of both, ending in the lion not only killing, but devouring his mate. Old lions, whose teeth have been forever injured with constant wear, become "man-eaters," finding their easiest means of obtaining a subsistence in lurking about the neighbourhood of villages, and dashes into the tents at night and carrying off one of the sleeping inmates. Lions never climb.

With regard to the character of the lion, those who have had..."
opportunities of observing it in its native haunts differs greatly. The accounts of early writers as to its courage, nobility and magnanimity have led to a reaction, causing some modern authors to accuse it of cowardice and meanness. Livingstone goes so far as to say, "nothing that I ever learned of the lion could lead me to attribute to it either the ferocious or noble character ascribed to it elsewhere," and he adds that its roar is not distinguishable from that of the ostrich. These different estimates depend to a great extent upon the particular standard of the writer, and also upon the circumstance that lions, like other animals, show considerable individual differences in character, and behave differently under varying circumstances.

(W. H. F.; R. L.*)

LIONNE, HUGUES DE (1611-1671), French statesman, was born at Grenoble on the 11th of October 1611, of an old family of Dauphiné. Early trained for diplomacy, his remarkable abilities attracted the notice of Cardinal Mazarin, who sent him as secretary of the French embassy to the congress of Münster, and, in 1642, on a mission to the pope. In 1646 he became secretary to the queen regent; in 1653 obtained high office in the king's household; and in 1654 was ambassador extraordinary at the election of Pope Alexander VII. He was instrumental in forming the league of the Rhine. When the league dissolved, Mazarin, at the Spanish Netherlands, and, as minister of state, was associated with Mazarin in the Peace of the Pyrenees (1659), which secured the marriage of Louis XIV. to the infanta Maria Theresa. At the cardinal's dying request he was appointed his successor in foreign affairs, and, for the next ten years, continued to direct French foreign policy. Among his most important diplomatic successes were the treaty of Breda (1667), the treaty of Aix-la-Chapelle (1668) and the sale of Dunkirk. He died in Paris on the 1st of September 1671, leaving memoirs. He was a man of pleasure, but his natural indolence gave place to an unflagging energy when the occasion demanded it; and, in an age of great ministers, his consummate statesmanship placed him in the front rank.

LIOTARD, JEAN ETIENNE (1702-1769), French painter, was born at Geneva. He began his studies under Professor Gardelle and Petiot, whose engravings and miniatures he copied with considerable skill. He went to Paris in 1725, studying under J. B. Massé and F. le Moyne, on whose recommendation he was taken to Naples by the Marquis Puisieux. In 1735 he was in Rome, painting the portraits of Pope Clement XII. and several cardinals. Three years later he accompanied Lord Duncannon to Constantinople, whence he went to Vienna in 1742 to paint the portraits of the imperial family. His eccentric adoption of oriental costume secured for him the nickname of "the Turkish painter." Still under distinguished patronage he returned to Paris in 1744 visited England, where he painted the princess of Wales in 1753, and went to Holland in 1756, where, in the following year, he married Marie Fargues. Another visit to England followed in 1772, and in the next two years his name figures among the Royal Academy exhibitors. He returned to his native town in 1776 and died at Geneva in 1780.

Liotard was an artist of great versatility, and though his fame depends largely on his fantasies and delicate pastel drawings, he made notable use of the "Chinese Girl," and "La Belle Lyonnaise" at the Dresden Gallery are delightful examples. He achieved distinction by his engravings, copperplate engravings and glass painting. He also wrote a Treatise on the Art of Painting, and was an expert collector of paintings by the old masters. Many of the masterpieces he had acquired were sold by him at high prices on his second visit to England. The museums of Amsterdam, Berne, and Geneva are particularly rich in examples of his paintings and pastel drawings. A picture of a Turk seated at the Victoria and Albert Museum, while the British Museum owns two of his drawings. The Louvre has, besides twenty-two drawings, a portrait of General Hérald and a portrait of the artist to be found at the Sala dei pittori, in the Uffizi Gallery, Florence.

See La Vie et les œuvres de Jean Etienn Eiotard (1702-1759), édité biographique et iconographique, by E. Humbert, A. Revilliod, and J. W. R. Tilanus (Amsterdam, 1897).

LIP (a word common in various forms to Teutonic languages, e.g. Ger. Lippe, Dan. laebe; Lat. labium is cognate), one of the two fleshy protuberant edges of the mouth in man and other animals, hence transferred to such objects as resemble a lip, the edge of a circular or other opening, as of a shell, or of a wound, or of any fissure in anatomy and zoology; in this last usage the Latin labium is more usually employed. It is also used of any projecting edge, as in coal-mining, &c. Many figurative uses are derived from the connexion with the mouth as the organ of speech. In architecture "lip moulding" is a term given to a moulding employed in the Perpendicular period, from its resemblance to an overhanging lip. It is often found in base mouldings, and is not confined to England, there being similar examples in France and Italy.

LIPA, a town of the province of Batangas, Luzon, Philippine Islands, about 90 miles S. by E. of Manila. Pop. (1903) 37,934. Lipa is on high ground at the intersections of old military roads, with its cool and healthy climate, and is one of the largest and wealthiest inland towns of the archipelago. Many of its houses have two stories above the ground-floor, and its church and convent together form a very large building. The surrounding country is very fertile, producing sugar-cane, Indian corn, cacao, tobacco and indigo. The cultivation of coffee was begun here on a large scale about the middle of the 19th century and was increased gradually until 1859-1860 when an insect pest destroyed the trees. The language of Lipa is Tagalog.

LIPAN, a tribe of North American Indians of Ahtahaskan stock. Their former range was central Texas. Later they were driven into Mexico. They were pure nomads, lived entirely by hunting, and were perhaps the most daring of the Texas Indians. A few survivors were brought back from Mexico in 1905 and placed on a reservation in New Mexico.

LIPARI ISLANDS (anc. Aethusa major, or Aeolias Insulae), a group of volcanic islands N. of the eastern portion of Sicily. They are two in number—Lipari (Lipara), pop. in 1901, 1,529; Stromboli (Strongyle), Salina (Didyma), in 1901, 1,014, Filicuri (Phoenicusa), Alicuri (Ericusa), Vulcano (Hiera, Therasia or Thermissa), the mythical abode of Hephaestus, and Panarea (Eunomusa). The island of Aiolic, the home of Aiolos, lord of the winds, which Ulysses twice visited in his wanderings, has generally been identified with one of this group. A colony of Cnidian and Rhodians was established on Lipara in 350-377 B.C. The inhabitants were allied with the Syracusans, and were attacked by the Athenian fleet in 427 B.C., and by the Carthaginians in 397 B.C., while Agathocles plundered a temple on Lipara in 301 B.C. During the Punic wars the islands were a Carthaginian naval station of some importance until the Romans took possession of them in 252 B.C. Sextus Pompeius also used them as a naval base. Under the Empire the islands served as a place of banishment for political prisoners. In the middle ages they frequently changed hands. The island of Lipari contains the chief town (population in 1901, 3853), which bears the same name and had municipal rights in Roman times. It is the seat of a bishop. It is fertile and contains sulphur springs and hot springs. The towns of Lipari and Stromboli are noted for their wines, which are considered the best in the islands.

Pumicestone is exported.

Stromboli, 22 m. N.E. of Lipari, is a constantly active volcano, ejecting gas and lava at brief intervals, and always visible at night. Salina, 3 m. N.W. of Lipari, consisting of the cones of two extinct volcanoes, that on the S.E., Monte Salvatore (315 ft.), being the highest point in the islands, is the most fertile of the whole group and produces good Malmsey wine: it takes its name from the salt-works on the south coast. Vulcano, 3 m. 1 Greek coins of the Lipari Islands are preserved in the museum at Cefalú.

1 Greek coins of the Lipari Islands are preserved in the museum at Cefalú.
S. of Lipari, contains a still smoking crater. Sulphur works were started in 1874, but have since been abandoned.

See Archduke Ludwig Salvator of Austria, Die Liparischen Inseln, 8 vols. (for private circulation) (Prague, 1893 seqq.).

LIPETSK, a town of Russia, in the government of Tambov, 108 m. by rail W. of the city of Tambov, on the right bank of the river Voronezh. Pop. (1897) 16,353. The town is built of wood and the streets are unpaved. There are sugar, tallow, and leather works, and distilleries, and an active trade in horses, cattle, tallow, skins, honey and timber. The Lipetsk mineral springs (chalybeate) came into repute in the time of Peter the Great and attract a good many visitors.

LIPPE, a river of Germany, a right-bank tributary of the Rhine. It rises near Lippespringe under the western declivity of the Teutoburger Wald, and, after being joined by the Alme, the Pader and the Alse on the left, and by the Stever on the right, flows into the Rhine near Wesel, after a course of 154 m. It is navigable downwards from Lippstadt, for boats and barges, by the aid of twelve locks, drawing less than 4 ft. of water. The river is important for the transport facilities it affords to the rich agricultural districts of Westphalia.

LIPPE, a principality of Germany and constituent state of the German empire, bounded N., W., and S. by the Prussian province of Hanover, and E. by the province of Lippe-Brake. It also possesses three small enclaves—Kappel and Lipperode in Westphalia and Grevenhagen near Hünxe. The area is 469 sq. m., and the population (1905) 145,610, showing a density of 125 to the sq. m. The greater part of the surface is hilly, and in the S. and W., where the Teutoburger Wald practically forms its physical boundary, mountainous. The chief rivers are the Weser, which crosses the north extremity of the principality, and its affluents, the Werre, Exter, Kalle and Emmer. The Lippe, which gives its name to the country, is a purely Westphalian river and does not touch the principality at any point. The forests of Lippe, among the finest in Germany, produce abundance of excellent timber. They occupy 28% of the whole area, and consist mostly of deciduous trees, beech preponderating. The valleys contain a considerable amount of good arable land, the tillage of which employs the greater part of the inhabitants. Small farms, the larger proportion of which are under 25 acres, are numerous, and their yield shows a high degree of prosperity among the peasant farmers. The principal crops are potatoes, beetroot (for Prussian packhorses), barley, wheat, rye, oats, and barley. Cattle, sheep and swine are also reared, and the “Senner” breed of horses, in the stud farm at Lopshorn, is celebrated. The industries are small and consist mainly in the manufacture of starch, paper, sugar, tobacco, and in weaving and brewing. Lemgo is famous for its meerschaum pipes and Salzungen for its brine-springs, producing annually about 1300 tons of salt, which is mostly exported. Each year, in spring, about 15,000 brickmakers leave the principality and journey to other countries, Hungary, Sweden and Russia, to return home in the late autumn.

The roads are well laid and kept in good repair. A railway intersects the country from Herford (on the Cologne-Hanover main line) to Altenbeken; and another from Bielefeld to Hameln traverses it from W. to E. More than 95% of the population in 1905 were Protestants. Education is provided for by two gymnasias and numerous other efficient schools. The principality contains seven small towns, the chief of which are Detmold, the seat of government, Lemgo, Horn and Blomberg. The present constitution was granted in 1836, but it was altered in 1865, and again in 1875. It provides for a representative chamber of twenty-one members, whose functions are mainly consultative. For electoral purposes the population is divided into three classes, rated according to taxation, each of which returns seven members. The courts of law are centred at Detmold, whence an appeal lies to the court of appeal at Celle in the Prussian province of Hanover. The estimated revenue in 1909 was £13,000 and the expenditure £11,000. The public debt in 1908 was £64,000. Lippe has one vote in the German Reichstag, and also one vote in the Bundesrat, or federal council. Its military forces form a battalion of the 6th Westphalian infantry.

History.—The present principality of Lippe was inhabited in early times by the Cherusci, whose leader Arminius (Hermann) annihilated in A.D. 9 the legions of Varus in the Teutoburger Wald. It was afterwards occupied by the Saxons and was subdued by Charlemagne. The founder of the present reigning family, one of the most ancient in Germany, was Bernard I. (1113-1144), who received a grant of the territory from the emperor Lothair, and assumed the title of lord of Lippe (eller Herr von Lippe). He was descended from a certain Hooel who had abouted himself with 9500. Bernard’s successors inherited or obtained several counties, and one of them, Simon III. (d. 1410), introduced the principles of primogeniture. Under Simon V. (d. 1536), who was the first to style himself count, the Reformation was introduced into the country. His grandson, Simon VI. (1555-1613), is the ancestor of both lines of the princes of Lippe. In 1613 the country, as it then existed, was divided among his three sons, the lines founded by two of whom still exist, while the third (Brake) became extinct in 1700. Lippe proper was the patrimony of the eldest son, Simon VII. (1587-1627), upon whose descendant Frederick William Leopold (d. 1802) the title of princes of the empire was bestowed in 1789, a dignity already conferred, though not confirmed, in 1720. Philip, the eldest son of Simon VI., received but a scantly part of his father’s possessions, but in 1640 he inherited a large part of the county of Schaumburg, including Bückeburg, and adopted the title of count of Schaumburg-Lippe. The ruler of this territory became a sovereign prince in 1807. Simon VII. had a younger son, Jobst Hermann (d. 1678), who founded the line of counts of Lippe-Biesterfeld, and a cadet branch of this family were the counts of Lippe-Weissenfeld. In 1762 these two counties—Biesterfeld and Weissenfeld—passed by arrangement into the possession of the senior and ruling branch of the family. Under the prudent government of the princes Pauline (from 1802 to 1820), widow of Frederick William Leopold, the little state enjoyed great prosperity. In 1807 it joined the Confederation of the Rhine and in 1813 the German Confederation. Pauline’s son, Paul Alexander Leopold, who reigned from 1820 to 1851, also ruled in a wise and liberal spirit, and in 1836 granted the charter of rights upon which the constitution is based. In 1842 Lippe entered the German Customs Union (Zollverein), and in 1866, though its lot with Prussia and joined the North German Confederation.

The line of rulers in Lippe dates back, as already mentioned, to Simon VI. But besides this, the senior line, the two collateral lines of counts, Lippe-Biesterfeld and Lippe-Weissenfeld and the princely line of Schaumburg-Lippe, also trace their descent to the same ancestor, and these three lines stand in the above order as regards their rights to the Lippe succession, the counts being descended from Simon’s eldest son and the princes from his youngest son. These facts were not in dispute when in March 1805 the death of Prince Woldemar, who had reigned since 1875, raised a dispute as to the succession. Woldemar’s brother Alexander, the last of the senior line, was hopelessly insane and had been declared incapable of ruling. On the death of Woldemar, Prince Adolph of Schaumburg-Lippe, fourth son of Prince Adolph George of that country and brother-in-law of the German emperor, took over the regency by virtue of a decree issued by Prince Woldemar, but which had until the latter’s death been kept secret. The Lippe house of representatives consequently passed a special law confirming the regency in the person of Prince Adolph, but with the proviso that the regency should be at an end as soon as the disputes touching the succession were adjusted; and with a further proviso that, should this dispute not have been settled before the death of Prince Alexander, then, if a competent court of law had been secured before that event happened, the regency of Prince Adolph should continue until such court had given its decision. The dispute in question had arisen because the heads of the two collateral county lines had arisen because the heads of the two collateral county lines had
entered a canoni. In order to adjust matters the Lippe government moved the \textit{Bundesrat}, on the 9th of July 1895, to pass an imperial law declaring the \textit{Reichsgesetz} (the supreme tribunal of the empire) a competent court to adjudicate upon the claims of the rival lines to the succession. In consequence the \textit{Bundesrat} passed a resolution on the 1st of February 1896, requesting the chancellor of the empire to bring about a compromise for the appointment of a court of arbitration between the parties. Owing to the mediation of the chancellor a compact was on the 3rd of July 1896 concluded between the heads of the three collateral lines of the whole house of Lippe, binding "both on themselves and on the lines of which they were the heads." By clause 2 of this compact, a court of arbitration was to be appointed, consisting of the king of Saxony and six members selected by him from among the members of the supreme court of law of the empire. This court was duly constituted, and on the 22nd of June 1897 delivered judgment to the effect that Count Ernest of Lippe-Biesterfeld, head of the line of Lippe-Biesterfeld, was entitled to succeed to the throne of Lippe on the death of Prince Alexander. In consequence of this judgment Prince Adolph resigned the regency and Count Ernest became regent in his stead. On the 26th of September 1904 Count Ernest died and his eldest son, Count Leopold, succeeded to the regency; but the question of the succession was again raised by the prince of Schaumburg-Lippe, who urged that the marriage of Count William Ernest, father of Count Ernest, with Modeste von Unruh, and that of the count regent Ernest himself with Countess Carlène von Wartensleben were not 	extit{ebenbürtig} (equal birth), and that the present prince in the line of his house was no more a prince of the Lippe-Str componentDidUpdate(257) erfeld family than his own father, who ought therefore to be recognized as the heir to the succession. Prince George of Schaumburg-Lippe and the count regent, Leopold, thereupon entered into a compact, again referring the matter to the \textit{Bundesrat}, which requested the chancellor of the empire to agree to the appointment of a court of arbitration consisting of two civil senates of the supreme court, sitting at Leipzig, to decide finally the matter in dispute. It was further provided in the compact that Leopold should remain as regent, even after the death of Alexander, until the decision of the court had been given. Prince Alexander died on the 13th of January 1905; Count Leopold remained as regent, and on the 25th of October the court of arbitration issued its award, declaring the marriages in question (which were, as proved by document, contracted with the consent of the head of the house of Schaumburg, and that of the accused party was aware of the king of Saxony the family of Lippe-Biesterfeld, together with the collateral lines sprung from Count William Ernest (father of the regent, Count Ernest) were in the order of nearest agnates called to the succession. Leopold (b. 1871) thus became prince of Lippe.

\textbf{LIPPI}, the name of three celebrated Italian painters.

\textbf{I. FRA FILIPPO LIPPI (1406-1469)}, commonly called Lippo Lippi, one of the most renowned painters of the Italian quattrocento, was born in Florence—his father, Tommaso, being a butcher. His mother died in his childhood, and his father survived his wife only two years. His aunt, a poor woman named Monna Lapaccia, then took charge of the boy; and in 1428, when fourteen years of age, he was registered in the community of the Carmelite friars of the Carmine in Florence. Here he remained till 1432, and his early faculty for fine arts was probably developed by studying the works of Masaccio in the neighbouring chapel of the Brancacci. Between 1430 and 1433 he executed some works in the monastery, which were destroyed by a fire in 1771; they are specified by Vasari, and one of them was particularly marked by its resemblance to Masaccio's style. Eventually Fra Filippo quitted his convent, but it appears that he was not relieved from some sort of religious vow; in a letter dated in 1439 he speaks of himself as the poorest friar of Florence, and says he is charged with the maintenance of six marriageable nieces. In 1452 he was appointed chaplain to the convent of S. Giovanni in Florence, and in 1457 rector (\textit{Rettore Comendatario}) of S. Quirico at Leganía, and his gains were considerable and uncommonly large from time to time; but his poverty seems to have been chronic, the money being spent, according to one account, in frequently recurring amours.

Vasari relates some curious and romantic adventures of Fra Filippo, which modern biographers are not inclined to believe. Except through Vasari, nothing is known of his visits to Ancona and Naples, and his intermediate capture by Barbary pirates and his subsequent employment in Bishop's service by whose sketch in portrait-sketching availed to release him. This relates to a period, 1433-1437, when his career is not otherwise clearly accounted for. The doubts thrown upon his semi-marital relations with a Florentine lady appear, however, to be somewhat arbitrary; Vasari's account is circumstantial, and in itself not greatly improbable.

Towards June 1456 Fra Filippo was settled in Prato (near Florence) for the purpose of fulfilling a commission to paint frescoes in the choir of the cathedral. Before actually undertaking this work he set about painting, in 1458, a picture for the convent chapel of S. Margherita of Prato, and there saw Lucrezia Buti, the beautiful daughter of a Florentine, Francesco Buti; she was either a novice or a young lady placed under the nuns' guardianship. Lippi asked that she might be permitted to sit for him in the cloister, and to make of her the figure of the Virgin on the altarpiece (of S. Margherita); he made passionate love to her, abducted her to his own house, and kept her there, though the utmost efforts the nuns could make to reclaim her. The fruit of their loves was a boy, who became the painter, not less celebrated than his father, Filippino Lippi (noticed below). Such is substantially Vasari's narrative, published less than a century after the alleged events; it is not refuted by saying, more than three centuries later, that perhaps Lippo had nothing to do with any such Lucrezia, and perhaps Filippino was his adopted son, or only an ordinary relative and scholar. The argument that two reputed portraits of Lucrezia in paintings by Lippo are not alike, one as a Madonna in a very fine picture in the Piti gallery, and the other in the same character in a Nativity in the Louvre, is one of the less conclusive. To very little; and it is reduced to nothing when the disputant adds that the Louvre painting is probably not done by Lippi at all. Besides, it appears more likely that not the Madonna in the Louvre but a S. Margaret in a picture now in the Gallery of Prato is the original portrait (according to the tradition) of Lucretia Buti.

The frescoes in the choir of Prato cathedral, being the stories of the Baptist and of St Stephen, represented on the two opposite wall spaces, are the most important and monumental works which Fra Filippo has left, more especially the figure of Salome dancing, and the last of the series, showing the ceremonial mourning over Stephen's corpse. This contains a portrait of the painter, but which is the proper figure is a question that has roused some diversity of opinion. At the end wall of the choir are S. Giovanni Gualberto and S. Alberto, and on the ceiling the four evangelists.

The close of Lippi's life was spent at Spoleto, where he had been commissioned to paint, for the apse of the cathedral, some scenes from the life of the Virgin. In the semidome of the apse is Christ crowning the Madonna, with angels, sibyls and prophets. This series, which is not wholly equal to the one at Prato, was completed by Fra Diamante after Lippi's death. That Lippi died in Spoleto, on or about the 8th of October 1469, is an undoubted fact; the mode of his death is again a matter of dispute. It has been said that the pope granted Lippi a dispensation for marrying Lucrezia, but that, before the permission arrived, he had been poisoned by the indignant relatives either of Lucrezia herself, or of some lady who had replaced her in the inconstant painter's affections. This is now generally regarded as a fable; and indeed a vendetta upon a man aged sixty-three for a
seduction committed at the already mature age of fifty-two seems hardly plausible. Fra Filippo lies buried in Spoleto, with a monument erected to him by Lorenzo the Magnificent; he had always been zealously patronized by the Medici family, beginning with Cosimo, Pater Patriae. Francesco di Pesello (called Peselino) and Sandro Botticelli were among his most distinguished pupils.

In 1441 Lippi painted an altarpiece for the nuns of S. Ambrogio which is now a prominent attraction in the Academy of Florence, and has been celebrated in Browning's well-known poem. It represents the coronation of the Virgin among angels and saints, of whom Saint Peter and John, who may be seen in the middle right, is a half-length portrait of Lippo, pointed out by an inscription upon an angel's scroll "Is perfect opus." The price paid for this work in 1447 was 1200 Florentine lire, which seems surprisingly large. It was published in a fresh and praised altarpiece for St Bernard, a fine specimen still extant. His principal altarpiece in this city is a Nativity in the refectory of S. Domenico—the Infant on the ground adored by the Virgin and Joseph, between Sts George and Dominic, in a rocky landscape, with the shepherd and six angels in the sky. In the Uffizi is a fine Virgin adorning the infant Christ, who is held by two angels; in the National Gallery, London, a "Vision of St Bernard." The picture of the "Virgin and Infant with an Angel," in the same gallery, also ascribed to Lippi, is disputable.

Few pictures are so thoroughly enjoyable as those of Lippo Lippi; they show the naiveté of a strong, rich nature, redundant in lively and somewhat whimsical observation. He approaches religious art from its highest and most spiritual point of view, and shuns the conventional and devotion. He was perhaps the greatest colourist and technical adept of his time, with good draughtsmanship—a naturalist, with less vulgar realism than some of his contemporaries, and with much genuine episodical animation, including semi-humorous incidents and low characters. He made little effort after perspective and none for foreshortenings, was fond of ornamenting pilasters and other architectural features. Vasari says that Lippi was wont to hide the extremities of draperies and disciples of his clear-cut details, to the great enjoyment of his hermits and devotion. We have preferred to follow the more usual account. The self-portrait dated 1441 looks like a man much older than twenty-nine.

Along with Vasari's interesting and amusing, and possibly not very authentic, account of Lippo Lippi, the work of Crowe and Cavalcaselle should be consulted. Also: E. C. Strutt, Fra Lippo Lippi (1901); C. M. Phillimore, Early Florentine Painters (1881); B. Supino, Fra Lippo Lippi (Illustrated) (1902). It should be observed that Crowe and Cavalcaselle give 1448 as the date of the painter's birth, and this would make a considerable difference in estimating details of his after career. We have preferred to follow the more usual account. The self-portrait dated 1441 looks like a man much older than twenty-nine.

II. FILIPPINO, OR FILIPPO LIPPI (1450-1505), was the natural son of Fra Lippo Lippi and Lucrezia Buti, born in Florence and educated at Prato. Losing his father before he had completed his tenth year, the boy took up his avocation as a painter, studying under Sandro Botticelli and probably under Fra Diamante. The style which he formed was in great extent original, but it bears clear traces of the manner both of Lippo and of Botticelli—more ornamental than the first, more realistic and less poetical than the second. His powers developed early; for we find him an accomplished artist by 1480, when he painted an altarpiece, the "Vision of St Bernard," now in the Badia of Florence; it is in tempera, with almost the same force as oil painting. Soon afterwards, probably from 1482 to 1490, he began to work upon the frescoes which completed the decoration of the Brancacci chapel in the Carmine, commenced by Masolino and Masaccio many years before. He finished Masaccio's "Resurrection of the King's Son," and was the sole author of "Paul's Interview with Peter in Prison," the "Liberation of Peter," the "Two Saints before the Proconsul," and the "Crucifixion of Peter." These works are sufficient to prove that Filippino stood in the front rank of the artists of his time. The dignified and expressive figure of St Paul in the second-named subject has always been particularly admired, and appears to have furnished a suggestion to Raphael for his "Paul at Athens." Portraits of Luigi Pulci, Antonio Poli, Lippino himself and various others are in this series. In 1495 he executed the great altarpiece for the "Virgin and Saints," with several other figures, now in the Uffizi Gallery. Another of his leading works is the altarpiece for the Nerli chapel in S. Spirito—the "Virgin Enthroned," with splendidly living portraits of Nerli and his wife, and a throned distance. In 1498 Lippi was in Rome, painting in the church of the Minerva, having first passed through Spoleto to design the monument for his father in the cathedral of that city. Some of his principal frescoes in the Minerva are still extant, the subjects being in celebration of St Thomas Aquinas. In one picture the saint is miraculously commended by a crucifix; in another, triumphing over heretics. In 1506 Lippi painted the "Adoration of the Magi," now in the Uffizi, a very striking picture, with numerous figures. This was succeeded by his last important undertaking, the frescoes in the Strozzi chapel, in the church of S. Maria Novella in Florence—"Drusiana Restored to Life by St John, the Evangelist," "St John in the Cauldron of Boiling Oil" and two subjects from the legend of St Philip. These are conspicuous and attractive works, yet somewhat grotesque and exaggerated—full of ornate architecture, showy colour and the distinctive peculiarities of the master. Filippino, who had married in 1497, died in 1505. The best reputed of his scholars was Raffaellino del Garbo.

Like his father, Filippino had a most marked original genius for painting, and he was hardly less a chief among the artists of his time than Fra Filippo had been in his; it may be said that in all the annals of the art a rival instance is not to be found of a father and son who had such preeminence in nature gifts and leadership. The father displayed more of sentiment and candid sweetness of motive; the son more of richness, variety and lively pictorial combination. He was admirable in all matters of decorative adjunct and presentation, such as representing landscape background, and in perspective, the rarest gift of Florence, he introduced a taste for antique details of costume, &c. He formed a large collection of objects of this kind, and left his designs of them to his son. In his later works there is a tendency to a mannered development of the extremities, and generally to lack of economy. The National Gallery, London, possesses a good and characteristic though not exactly a first-rate specimen of Filippino, the "Virgin and Child between Sts Jerome and Dominic"; also an "Adoration of the Holy Child," one of which was hung in the chancel of the Florentine cathedral, and has been described by Crowe and Cavalcaselle, supplemented by the writings of Berenson, should be consulted as to this painter. An album of his works is in News’ Art Library.

III. LORENZO LIPPI (1606-1664), painter and poet, was born in Florence. He studied painting under Matteo Rosselli, the influence of whose style, and more especially of that of Santi di Tito, is to be traced in Lippi’s works, which are marked by taste, delicacy and a strong turn for portrait-like naturalism. His maxims were "to poetically as he spoke, and to paint as he saw." After exercising his art for some time in Florence, and having married at the age of forty the daughter of a rich sculptor named Susini, Lippi went as court painter to Innsbruck, where he has left many excellent portraits. There he wrote his humorous poem named Malmanute Raccquistato, which was published under the anagrammatic pseudonym of "Perlo Zitoli." Lippi was somewhat self-sufficient, and, when visiting Parma, would not look at the famous Correggios there, saying that they could teach him nothing. He died of pleurisy in 1664, in Florence.

The most esteemed works of Lippi as a painter are a "Cruci-fixion" in the Uffizi gallery at Florence, and a "Triumph of David." He painted in 1478 the celebrated fresco in the Brancacci gallery in the date of the painter’s birth, and this would make a considerable difference in estimating details of his after career. We have preferred to follow the more usual account. The self-portrait dated 1441 looks like a man much older than twenty-nine.

LIPPSPRINGE, a town and watering-place in the Prussian province of Westphalia, lying under the western slope of the Teutoburger Wald, 5 m. N. of Paderborn. Pop. (1905) 3100. The springs, the Arminius Quelle and the Lippi Quelle, for which it is famous, are saline waters of a temperature of 70° F., and are utilized both for bathing and drinking in cases of pulmonary consumption and chronic diseases of the respiratory organs. The annual number of visitors amounts to about 6000. Lippespringe is mentioned in chronicles as early as the 8th century, but
and here in the 14th century the order of the Templars established a stronghold. It received civic rights about 1400.

See Damann, Der Kurort Lippspringe (Paderborn, 1900); König, Lippspringe (Berlin, 1893); and Frey, Lippspringe, Kurort für Lungenerkrankte (Paderborn, 1899).

LIPPSCHRUP, a town in the Prussian province of Westphalia, on the river Lippe, 20 m. by rail W. by S. of Paderborn, on the main line to Düsseldorf. Pop. (1905) 15,436. The Marien Kirche is a large edifice in the Transitional style, dating from the 13th century. It has several schools, among them being one which was originally founded as a nunnery in 1185. The manufactures include cigar-making, distilling, carriage-building and metal-working.

Lipsstadt was founded in 1168 by the lords of Lippe, the rights over one half of the town passing subsequently by purchase to the counts of the Mark, which in 1614 was incorporated with Brandenburg. In 1850 the prince of Lippe-Detmold sold his share to Prussia when this joint lordship ceased. In 1620 Lipsstadt was occupied by the Spaniards and in 1757 by the French.

See Chalybäus, Lipsstadt, ein Beitrag zur deutschen Städtgeschichte (Lipsstadt, 1876).

LIPSUS, JUSTUS (1547–1606), the Latinized name of Joest (Juste or Josse) Lips, Belgian scholar, born on the 8th of October (13th of November, according to Amel) 1547 at Overysche, a small village in Brabant, near Brussels. Sent early to the Jesuit college in Cologne, he was removed at the age of sixteen to the university of Louvain by his parents, who feared that he might be induced to become a member of the Society of Jesus. The publication of his Variarum Legationum Libri Tres (1567), dedicated to Cardinal Granvelle, procured him an appointment as Latin secretary and a visit to Rome in the person of the cardinal. Here Lipsius remained two years, devoting his spare time to the study of the Latin classics, collecting inscriptions and examining MSS. in the Vatican. A second volume of miscellaneous criticism (Antiquarum Legationum Libri Quinque, 1575), published after his return from Rome, compared with the Variarum Legationum of eight years earlier, shows that he had advanced from the notion of purely conjectural emendation to that of emending by collation. In 1570 he wandered over Burgundy, Germany, Austria, Bohemia, and was engaged for more than a year as teacher in the university of Jena, a position which implied an outward conformity to the Lutheran Church. On his way back to Louvain, he stopped some time at Cologne, where he must have come to himself as a Catholic. He then returned to Louvain, but was soon driven by the civil war to take refuge in Antwerp, where he received, in 1579, a call to the newly founded university of Leiden, as professor of History. At Leiden, where he must have passed as a Calvinist, Lipsius remained eleven years, the period of his greatest productivity. It was now that he prepared his Seneca, perfected, in successive editions, his Tacitus and brought out a series of works, some of pure scholarship, others collections from classical authors, others again of general interest. Of this latter class was a treatise on politics (Politicorum Libri Sex, 1586), in which he showed that, though a public teacher in a country which professed toleration, he had not departed from the state maxims of Alva and Philip II. He lays it down that a government should recognize only one religion, and that dissent should be extirpated by fire and sword. From the attacks to which this avowal exposed him, he was saved by the prudence of the authorities of Leiden, who prevailed upon him to publish a declaration that his expression, Ure. sec., was a metaphor for a vigorous treatment. In the spring of 1590, leaving Leiden under pretext of taking the waters at Spa, he went to Mainz, where he was reconciled to the Roman Catholic Church. The event deeply interested the Catholic world, and invitations poured in on Lipsius from the courts and universities of Italy, Austria and Spain. But he preferred to remain in his own country, and finally settled at Louvain, as professor of Latin in the Collegium Bernardianum. He was not expected to teach, and his trifling stipend was eked out by the appointments of privy councillor and historiographer to the king of Spain. He continued to publish dissertations as before, the chief being his De militia romana (Antwerp, 1595) and Louvainum (Antwerp, 1605; 4th ed., Wesel, 1671), intended as an introduction to a general history of Brabant. He died at Louvain on the 23rd of March (some give 24th of April) 1606.

Lipsius's knowledge of classical antiquity was extremely limited. He had but slight acquaintance with Greek, and in Latin literature the poets and Cicero lay outside his range. His greatest work was his edition of Tacitus. This author he had so completely made his own that he could repeat the whole, and offered to be tested in any part of the text, with a poniard held to his breast, to be used against him if he should fail. His Tacitus first appeared in 1575, and was five times revised and corrected—the last time in 1696, shortly before his death. His Opera Omnia appeared in 8 vols. at Antwerp (1585, 2nd ed., 1637).

A full list of his publications will be found in van der Aa, Biographisch Woordenboek der Nederlanden (1865), and in Bibliographie Lipsiense (Ghent, 1886–1888). In addition to the biography by A. le Mire (Abbertus Miraeus) (1609), the only original account of his life, see M. E. C. Nisard, Le Triomphe littéraire au XVIIe siècle (1852); A. Rüss, Die Convertiten seii der Reformation (1867); P. Bergman's Autobiographie de J. Lipsé (1896); G. Galesco, Particularités sur la vie de J. Lipsé (1877); E. Amel, Un Publiciste au XVIIe siècle (1893); J. Dupre, Le Deisme et la philosophie classique (1890); J. de la Salle, L. P. in Louisiana, in the Nouvelle Biographie générale, and L. Roersch in Biographie nationale de Belgique, may also be consulted.

LIPSUS, RICHARD ADELBERT (1859–1892), German Protestant theologian, son of K. H. A. Lipsius (d. 1861), who was rector of the school of St Thomas at Leipzig, was born at Gera on the 14th of February 1859. He studied at Leipzig, and eventually (1871) settled at Jena as professor ordinarius. He helped to found the "Evangelical Protestant Missionary Union" and the "Evangelical Alliance," and from 1874 took an active part in their management. He died at Jena on the 19th of August 1892. Lipsius wrote principally on dogmatics and the history of early Christianity from a liberal and critical standpoint. A Neo-Kantian, he was to some extent an opponent of Albrecht Ritschl, demanding "a connected and consistent theory of the universe, which shall comprehend the entire realm of our experience as a whole. He rejects the doctrine of dualism in a truth, one division of which would be confined to 'judgments of value,' and be unconnected with our theoretical knowledge of the external world. The possibility of combining the results of our scientific knowledge with the declarations of our ethical-religious experience, so as to form a consistent philosophy, is based, according to Lipsius, upon the unity of the personal ego, which on the one hand knows the world scientifically, and on the other regards it as the means of realizing the ethical-religious object of its life" (Otto Pfleiderer). This, in part, is his attitude in Philosophie und Religion (1885). In his Lehrbuch der evangel.-prot. Dogmatik (1876; 3rd ed., 1893) he deals in detail with the doctrines of "God," "Christ," "Justification" and the "Church." From 1875 he assisted K. Hase, O. Pfleiderer and E. Schraeder in editing the Jahrbücher für prot. Theologie, and from 1885 till 1891 he edited the Theol. Jahresbericht.

His other works include Die Pilatusakten (1871, new ed., 1886), Dogmatische Beiträge (1878), Die Quellen der ältesten Ketzergeschichte (1875), Die apokryphen Apostelgeschichten (1883–1890), Hauptpunkte der christl. Glaubenslehre im Umriss dargestellt (1890), and commentaries on the Epistles to the Galatians, Romans and Philippians in H. J. Holtzmann's Handkommentar zum Neuen Testament (1891–1892).
liqueurs—liquid gases

purchased extensive tea, coffee and cocoa plantations in Ceylon, and provided his own packing-house for hogs in Chicago, and fruit farms, jam factories, bakeries and bacon-curing establishments in England. In 1856 his business was converted into a limited liability company. At Queen Victoria's diamond jubilee in 1897 he gave £30,000 for providing dinners for a large number of the London poor. In 1898 he was knighted, and in 1902 was made a baronet. In the world of yacht-racing he became well known from his repeated attempts to win the America Cup.

Liqueurs, the general term applied to perfumed or flavoured potable spirits, sweetened by the addition of sugar. The term "liqueur" is also used for certain wines and unsweetened spirits of very superior quality, or remarkable for their bouquet, such as toky or fine old brandy or whisky. The basis of all the "liqueurs" proper consists of (a) relatively strong alcohol or spirit, which must be as pure and neutral as possible; (b) sugar or syrup; and (c) flavouring matters. There are three distinct main methods of manufacturing liqueurs. The first, by which liqueurs of the highest class are prepared, is the "distillation" or "alcoholate" process. This consists in macerating various aromatic substances such as seeds, leaves, roots and bark of plants, &c., with strong spirit and subsequently distilling the infusion so obtained generally in the presence of a whole or a part of the macerating material. The second method, the "flavouring" or "flavouring matters which distils over is termed the "alcoholate." To this is added a solution of sugar or syrup, and frequently colouring matter in the shape of harmless vegetable extracts or burnt sugar, and a further quantity of flavouring matter in the shape of essential oils or clear spirituous vegetable extracts. The second method of making liqueurs is that known as the "essence" process. It is employed, as a rule, for cheap and inferior articles; the process resolving itself into the addition of various essential oils, either natural or artificially prepared, and of spirituous extracts to strong spirit, filtering and adding the saccharine matter to the clear filtrate. The third method of manufacturing liqueurs is the "infusion" process, in which alcohol and sugar are added to various fresh fruit juices. Liqueurs prepared by this method are frequently called "cordsals." It has been suggested that "cordsals" are articles of home manufacture, and that liqueurs are necessarily of foreign origin, but it is at least doubtful whether this is entirely correct. The French, who excel in the preparation of liqueurs, grade their products, according to their sweetness and alcoholic strength, into crèmes, huiles, bains, &c., which include the oils obtained from the same plant, and elder exracts or élixir, which, being less sweetened, are relatively limpid. Liqueurs are also classified, according to their commercial quality and composition, as ordinaires, demi-fin, fines and sur-fines. Certain liqueurs, containing only a single flavouring ingredient, or having a prevailing flavour of a particular substance, are named after that body, for instance, crème de vanille, anisette, kummel, crème de menthe, &c. On the other hand, many well-known liqueurs are compounded of very numerous aromatic principles. The nature and quantities of the flavouring agents employed in the preparation of liqueurs of this kind are kept strictly secret, but numerous "recipes" are given in works dealing with this subject. Among the substances frequently used as flavouring agents are aniseed, coriander, fennel, wormwood, gentian, sassafras, amber, hyssop, mint, thyme, angelica, citron, lemon and orange peel, peppermint, cinnamon, cloves, iris, caraway, tea, coffee and so on. The alcoholic strength of liqueurs ranges from close on 80% of alcohol by volume in some kinds of absinthe, to 37% in anisette. The liqueur industry is a very considerable one, there being in France some 25,000 factories. Most of these are small, but some 600,000 gallons are annually exported from France alone. For absinthe, benedictine, chartreuse, curaçoa, kirsch and vermouth see under separate headings. Among other well-known trade liqueurs may be mentioned maraschino, which takes its name from a variety of cherry—the marasca—grown in Dalmatia, the centre of the trade being at Zara; kummel, the flavour of which is largely due to caraway seeds; allasch, which is a rich variety of kummel; and cherry and other "fruit" brandies and whiskies, the latter being perhaps more properly termed cordials.

See Duplais, La Fabrication des liqueurs; and Rocques, Les Eaux-de-vie et liqueurs.

LIQUIDAMBAR, LIQUID AMBER OR SWEET GUM, a produt of Liquidambur styraciflua (order Hamamelidaceae), a deciduous tree of from 80 to 140 ft. high, with a straight trunk 4 or 5 ft. in diameter, a native of the United States, Mexico and Central America. It bears palmately-lobed leaves, somewhat resembling those of the maple, but larger. The male and female inflorescences are on different branches of the same tree, the globular heads of fruit resembling those of the plane. This species is nearly allied to L. orientalis, a native of a very restricted portion of the south-west coast of Asia Minor, where it forms forests. The earliest record of the tree appears to be in a Spanish work by F. Hernandez, published in 1631, in which he describes it as a large tree producing a fragrant gum resembling liquid amber, whence the name (Nov. Plant., &c., p. 36). In Ray's Historia Plantarum (1686) it is called Styrax liquida. It was introduced into Europe in 1681 by John Banister, the missionary collector sent out by Bishop Compton, who planted it in the palace gardens at Fulham. The wood is very compact and fine-grained—the heart-wood being reddish, and, when cut into planks, marked with a series of concentric rings and bordered with a beautiful yellow. It is employed for veneering in America. Being readily dyed black, it is sometimes used instead of ebony for picture frames, balusters, &c; but it is too liable to decay for out-door use.

The gum resin yielded by this tree has no special medicinal virtues, being inferior in therapeutic properties to many others of its class. Mixed with tobacco, the gum was used for smoking at the court of the Mexican emperors (Humboldt iv. 16). It has long been lost in France as a perfume for gloves, &c. It is mainly produced in Mexico, little being obtained from trees growing in higher latitudes of North America, or in England.

Liquidation (i.e. making "liquid" or clear), in law, the clearing off or settling of a debt. The word was more especially used in bankruptcy law to define the method by which, under the Bankruptcy Act 1860, the affairs of an insolvent debtor were arranged and a composition accepted by his creditors without actual bankruptcy. It was abolished by the Bankruptcy Act 1883 (see Bankruptcy). In a general sense, liquidation is used for the act of adjusting debts, as the Egyptian Law of Liquidation, July 1880, for a general settlement of the liabilities of Egypt. In company law, liquidation is the winding up and dissolving a company. The winding up may by either voluntary or compulsory. In the latter case, a liquidator is appointed, who takes into his custody all the property of the company and performs such duties as are necessary on its behalf (see Company).

Liquid Gases. Though Lavoisier remarked that if the earth were removed to very cold regions of space, such as those of Jupiter or Saturn, its atmosphere, or at least a portion of its aérom form, would return to the state of liquid (Essays, ii. 805), the history of the liquefaction of gases may be said to begin with the observation made by John Dalton in his essay "On the Force of Steam or Vapour from Water and various other Liquids" (1801): "There can scarcely be a doubt entertained respecting the reducibility of all elastic fluids of whatever kind into liquids; and we ought not to despair of effecting it in low temperatures and by strong pressures exerted on the unmixed gases." It was not, however, till 1823 that the question was investigated by systematic experiment. In that year Faraday, at the suggestion of Sir Humphry Davy, exposed hydrate of chlorine to heat under pressure in the laboratories of the Royal Institution. He placed the substance at the end of one arm of a bent glass tube, which was then hermetically sealed, and decomposing it by heating to 100° F, he saw a yellow liquid distil to the end of the other arm. This liquid he surmised to be chlorine separated from the water by the heat and "condensed into a dry fluid by the mere pressure of its own abundant vapour," and he verified his surmise by compressing chlorine gas, freed.
from water by exposure to sulphuric acid, to a pressure of about four atmospheres, with which the same yellow fluid was produced (Phil. Trans., 1833, 113, pp. 160-165). He proceeded to experiment with a number of other gases subjected in sealed tubes to the pressure caused by their own continuous production by chemical action, and in the course of a few weeks liquefied sulphuric acid, sulphuretted hydrogen, carbonic acid, ethylene, nitrous acid, cyanogen, ammonia, and muriatic acid, the last of which, however, had previously been obtained by Davy. But he failed with hydrogen, oxygen, fluoric, fluosillic and phosphuretted hydrogen gases (Phil. Trans., ib. pp. 189-198). Early in the following year he published an "Historical statement respecting the liquefaction of gases" (Quart. Journ. Sci., 1824, 16, pp. 229-240), in which he detailed several recorded cases in which previous experimenters had reduced certain gases to their liquid state.

In 1835 Thilorier, by acting on bicarbonate of soda with sulphuric acid in a closed vessel and evacuating the gas thus obtained under pressure into a second vessel, was able to accumulate large quantities of liquid carbonic acid, and found that when the liquid was suddenly ejected into the air a portion of it was solidified into a snow-like substance (Ann. chim. phys., 1835, 60, pp. 427-432). Four years later J. K. Mitchell in America, by mixing this snow with ether and exhausting it under an air-pump, attained a minimum temperature of 146° below zero F., by the aid of which he froze sulphuric acid gas to a solid.

Stimulated by Thilorier's results and by considerations arising out of the work of J. C. Cagniard de la Tour (Ann. chim. phys., 1822, 21, pp. 127 and 178, and 1823, 22, p. 410), which appeared to him to indicate that gases would pass by some simple law into the liquid state, Faraday returned to the subject about 1844, in the "hope of seeing nitrogen, oxygen and hydrogen either as liquid or solid bodies, and the latter probably as a metal" (Phil. Trans., 1845, 135, pp. 155-157). On the basis of Cagniard de la Tour's observation that at a certain temperature a liquid under sufficient pressure becomes a vapour or gas having the same bulk as the liquid, he inferred that "at this temperature or one a little higher, it is not likely that any increase of pressure, except perhaps one exceedingly great, would convert the gas into a liquid." He further surmised that the Cagniard de la Tour condition might have its point of temperature for oxygen, nitrogen, hydrogen, &c., below that belonging to the bath of solid carbonic acid and ether, and he realized that in that case no pressure which any apparatus would be able to bear would be able to bring those gases into the liquid or solid state, which would require a still greater degree of cold. To fulfill this condition he immersed the tubes containing his gases in a bath of solid carbonic acid and ether, the temperature of which was reduced by exhaustion under the air-pump to -166° F., or a little lower, and at the same time he subjected the gases to pressures up to 50 atmospheres by the use of two pumps working in series. In this way he added six substances, usually gaseous, to the list of those that could be obtained in the liquid state, and reduced seven, including ammonia, nitrous oxide and sulphuretted hydrogen, into the solid form, at the same time effecting a number of valuable determinations of vapour tensions. But he failed to condense oxygen, nitrogen and hydrogen, the original objects of his pursuit, though he found reason to think that "further diminution of temperature and improved apparatus for pressure may very well be expected to give us these bodies in the liquid or solid state." His surmise that increased pressure alone would not suffice to bring about change of state in these gases was confirmed by subsequent investigators, such as M. P. E. Berthelot, who in 1839 compressed oxygen to 780 atmospheres (Ann. chim. phys., 1850, 30, p. 237), and Natterer, who a few years later subjected the permanent gases to a pressure of 2790 atmospheres, without result; and in 1869 Thomas Andrews (Phil. Trans., 11) by his researches on carbonic acid finally established the conception of the "critical temperature" as that temperature, differing for different bodies, above which no gas can be made to assume the liquid state, no matter what pressure it is subjected to (see Condensation of Gases).

About 1877 the problem of liquefying the permanent gases was taken up by L. P. Cailletet and K. P. Pictet, working almost simultaneously though independently. The former relied on the cold produced by the sudden expansion of the gases at high compression. By means of a specially designed pump he compressed about 100 cc. of oxygen in a narrow glass tube to about 200 atmospheres, at the same time cooling it to about -20° C., and on suddenly releasing the pressure he saw momentarily in the interior of the tube a mist (brouillard), from which he inferred the presence of a vapour very near its point of liquefaction. A few days later he repeated the experiment with hydrogen, using a pressure of nearly 300 atmospheres, and observed in his tube an exceedingly fine and subtle fog which vanished almost instantaneously. At the time when these experiments were carried out it was generally accepted that the mist or fog consisted of minute drops of the liquefied gases. Even had this been the case, the problem would not have been completely solved, for Cailletet was unable to collect the drops in the form of a true stable liquid, and at the best obtained a "dynamic" not a "static" liquid, the gas being reduced to a form that bears the same relation to a true liquid that the partially condensed steam issuing from the funnel of a locomotive bears to water standing in a tumbler. But subsequent knowledge showed that even this proximate liquefaction could not have taken place, and that the fog could not have consisted of drops of liquid hydrogen, because the cooling produced by the adiabatic expansion would give a temperature of only 45° abs., which is certainly above the critical temperature of hydrogen. Pictet again announced that on opening the tap of a vessel containing hydrogen at a pressure of 650 atmospheres and cooled by the cascade method (see Condensation of Gases) to -140° C., he saw issuing from the orifice an opaque jet which he assumed to consist of hydrogen in the liquid form or in the liquid and solid forms mixed. But he was no more successful than Cailletet in collecting any of the liquid, which he had expected may have been, whether ordinary air or impurities associated with the hydrogen—cannot have been hydrogen because the means he employed were insufficient to reduce the gas to what has subsequently been ascertained to be its critical point, below which of course liquefaction is impossible. It need scarcely be added that if the liquefaction of hydrogen had been rejected a fortiori Pictet's claim to have effected its solidification falls to the ground.

After Cailletet and Pictet, the next important names in the history of the liquefaction of gases are those of Z. F. Wroblewski and K. S. Olszewski, who for some years worked together at Cracow. In April 1883 the former announced to the French Academy that he had obtained oxygen in a completely liquid state and (a few days later) that nitrogen at a temperature of -136° C., reduced suddenly from a pressure of 50 atmospheres to one of 50, had been seen as a liquid which showed a true meniscus, though disappered in a few seconds. But with hydrogen treated in the same way he failed to obtain even the mist reported by Cailletet. At the beginning of 1884 he performed a more satisfactory experiment. Cooling hydrogen in a capillary glass tube to the temperature of liquid oxygen, he expanded it quickly from 100 atmospheres to one, and obtained the appearance of an instantaneous ebullition. Olszewski confirmed this result by expanding from a pressure of 190 atmospheres the gas cooled by liquid oxygen and nitrogen boiling under reduced pressure, and even announced that he saw it running down the walls of the tube as a colourless liquid.

Wroblewski, however, was unable to observe this phenomenon, and Olszewski himself, when seven years later he repeated the experiment in the more favourable conditions afforded by a larger apparatus, was unable to produce again the colourless drops he had previously reported: the phenomenon of the appearance of sudden ebullition indeed lasted longer, but he failed to perceive any meniscus such as would have been a certain indication of the presence of a true liquid. Still, though neither of these investigators succeeded in reaching the goal at which they aimed, their work was of great value in elucidating the conditions of the problem and in perfecting the details of the
apparatus employed. Wroblewski, in particular devoted the closing years of his life to a most valuable investigation of the isothermal basis of hydrogen at low temperatures. From the data thus obtained he constructed a van der Waals equation which enabled him to calculate the critical temperature, pressure and density of hydrogen with very much greater certainty than had previously been possible. Liquid oxygen, liquid nitrogen and liquid air—the last was first made by Wroblewski in 1895—became something more than mere curiosities of the laboratory, and by the year 1891 were produced in such quantities as to be available for the purposes of scientific research. Still, nothing was added to the general principles upon which the work of Callmet and Pictet was based, and the “cascade” method, together with adiabatic expansion from high compression (see CONDENSATION OF GASES), remained the only means of procedure at the disposal of experimenters in this branch of physics.

In some quarters a certain amount of doubt appears to have arisen as to the sufficiency of these methods for the liquefaction of hydrogen. Olszewski, for example, in 1895 pointed out that the success of less and less condensable gases necessary for the cascade method breaks down between nitrogen and hydrogen, and he gave as a reason for hydrogen not having been reduced to the condition of a static liquid the non-existence of a gas intermediate in volatility between those two. By 1894 attempts had been made in the Royal Institution laboratories to manufacture an artificial gas of this nature by adding a small proportion of air to the hydrogen, so as to get a mixture with a critical point of about 200° C. When such a mixture was cooled to that temperature and expanded from a high degree of compression into a vacuum vessel, the result was a white mass of solid air together with a clear liquid of very low density. This was in all probability hydrogen in the true liquid state, but it was not found possible to collect it owing to its extreme volatility. Whether this artificial gas might ultimately have enabled liquid hydrogen to be collected in open vessels cannot be said, but experiments were abandoned in favour of other measures, which led finally to a more assured success.

Vacuum Vessels.—The problem involved in the liquefaction of hydrogen was in reality a double one. In the first place, the gas had to be cooled to such a temperature that the change to the liquid state was rendered possible. In the second, means had to be discovered for protecting it, when so cooled, from the influx of external heat, and since the rate at which heat is transferred from one body to another increases very rapidly with the difference between their temperatures, the question of efficient heat insulation became at once more difficult and more urgent in proportion to the degree of cold attained. The second part of the problem was in fact solved first. Of course packing with non-conducting materials was an obvious expedient when it was not necessary that the contents of the apparatus should be visible to the eye, but in the numerous instances when this was not the case such measures were not of the qo ex. Attempts made to surround the desired end by surrounding the vessel that contained the cooled or liquid gas with a succession of other vessels, through which was conducted the vapour given off from the interior one. Such devices involved awkward complications in the arrangement of the apparatus, and besides were not as a rule very efficient, although some workers, e.g. Dr Kamerlingh Onnes, of Leiden, reported some success with their use. In 1892 it occurred to Dewar that the principle of an arrangement he had used nearly twenty years before for some calorimetric experiments on the physical constants of hydrogenium, which was a natural deduction from the work of Dulong and Petit on radiation, might be employed with advantage as well to protect cold substances from heat as hot ones from cold. He therefore tried the effect of surrounding his liquefied gas with a highly exhausted space. The result was entirely successful. Experiment showed that liquid air contained in a glass vessel with two walls, the space between which was a high vacuum, evaporated at only one fifth the rate it did when in an ordinary vessel surrounded with air at atmospheric pressure, the convective transfer of heat by means of the gas particles being enormously reduced owing to the vacuum. But in addition these vessels lent themselves to an arrangement by which radiant heat could still further be cut off, since it was found that when the inner wall was coated with a bright deposit of silver, the influx of heat was diminished to one-sixth of the amount existing without the metallic coating. The total effect, therefore, of the high vacuum and silvering is to reduce the in-going heat to one-thirtieth part. In making such vessels a mercurial vacuum has been found very satisfactory. The vessel in which the vacuum is to be produced is provided with a small subsidiary vessel joined by a narrow tube with the main vessel, and connected with a powerful air-pump. A quantity of mercury having been placed in it, it is heated in an oil- or air-bath to about 200° C, so as to volatilize the mercury, the vapour of which is removed by the pump. After the process has gone on for some time, the pipe leading to the pump is sealed off, the vessel immediately removed from the bath, and the small subsidiary part immersed in some cooling agent such as solid carbonic acid or liquid air, whereby the mercury vapour is condensed in the small vessel and vacuum of enormous tenacity left in the large one. The final step is to seal off the tube connecting the two. In this way a vacuum may be produced having a vapour pressure of about the hundred-millionth of an atmosphere at 0° C. If, however, some liquid mercury be left in the space in which the vacuum is produced, and the containing part of the vessel be filled with liquid air, the bright mirror of mercury which is deposited on the inside wall of the bulb is still more effective than silver in protecting the chamber from the influx of heat, owing to the high refractive index, which involves great reflecting power, and the bad heat-conducting powers of mercury.

With the discovery of the remarkable power of gas absorption possessed by charcoal cooled to a low temperature (see below), it became possible to make these vessels of metal. Previously this could not be done with success, because gas occluded in the metal gradually escaped and vitiated the vacuum; but now an array of gas may be absorbed by means of charcoal so placed in a pocket within the vacuous space that it is cooled by the liquid in the interior of the vessel. Metal vacuum vessels (fig. 1), of a capacity of from 2 to 20 litres, may be formed of brass, copper, nickel or tinned iron, with necks of some alloy that is a bad conductor of heat, silvered glass vacuum cylinders being fitted as stoppers. Such flasks, when properly constructed, have an efficiency equal to that of the chemically-silvered glass vacuum vessels now commonly used in low temperature investigations, and they are obviously better adapted for transport. The principle of the Dewar vessels a utilized in the Thermos flasks which are now extensively manufactured and employed for keeping liquids warm in hospitals, &c.

Thermal Transparency at Low Temperatures.—The proposition, once enunciated by Pictet, that at low temperatures all substances have practically the same thermal transparency, and are equally ineffective as non-conductors of heat, is based on erroneous observation. It is true that if the space between the two walls of a double-walled vessel is packed with substances like carbon, magnesia, or silica, liquid air placed in the interior will boil off even more quickly than it will when the space merely contains air at atmospheric pressure, but in such cases it is not so much the carbon, &c., that bring about the transference of heat, as the air contained in their interstices. If this air be pumped out such substances are seen to exert a very considerable influence in stopping the influx of heat, the thin vessel between its two walls filled with a non-conducting material of this kind preserves a liquid gas even better than one in which that space is simply exhausted of air. In experiments on this point double-walled glass tubes, as nearly identical in shape and size as possible, were mounted in sets of three on a common stem which communicated with an air-pump so that the degree of exhaustion in each was equal. In two of each three the space between the double walls was filled with the powdered material it was desired to test, the third being left empty and used as the standard. The time required for a certain quantity of liquid
LIQUID GASES

It appears from these experiments that silica, charcoal, lampblack, and oxide of bismuth all increase the heat insulations to four, five and six times that of the empty vacuum space. As the chemical combination of heat through an exhausted space by molecular bombardment, the fine powders must shorten the free path of the gaseous molecules, and the slow conduction of heat through the porous mass must make the conveyance of heat energy more difficult than when the gas molecules can impinge upon the relatively hot outer glass surface, and then directly on the cold one without interruption. (See Proc. Roy. Inst. xv. 821-822-823.)

Density of Solids and Coefficients of Expansion at Low Temperatures.—The facility with which liquid gases, as carbon dioxide, can be compressed by evaporation from the proper use of vacuum vessels (see above) naturally suggests that the specific gravities of solid bodies can be got by direct weighing in such fluids. If the density of the liquid gas is accurately known, then the loss of weight by fluid displacement gives the specific gravity compared to water. The metals and alloys, or substances that can be got in large crystals, are the easiest to manipulate. If the body is only to be had in small crystals, then it must be compressed under strong hydraulic pressure into coherent blocks weighing about 40 to 50 grammes. Such an amount of material gives a very accurate density of the body about the boiling point of air, and a similar density taken in a solid body at the ordinary temperature enables the mean coefficient of expansion between +7° and +15° C. to be determined. It is found that the increase of the most interesting results is that the density of ice at the boiling point of air is not more than 0.93, the mean coefficient of expansion being therefore 0.000081. For the value of the same coefficient between 0° C. and -17° C. is 0.00011, it is clear that the rate of contraction is diminished to about one-half of what it was above the melting point of the ice. This suggests that by no possible cooling at our command is it likely we could ever make ice as dense as water at 0° C., far less 4° C. In other words, the volume of the water at the zero temperature would not be the minimum volume of the water molecule, though we have every reason to believe it would be in the case of the majority of known substances. Another substance of special interest is solid carbonic acid. This body, with a density of 1.01798 at 0° C., and 1.02842 at -18° C., gives a mean coefficient of expansion between these temperatures of 0.000457. This value is only about 1/6 of the coefficient of expansion of the liquid carbonic acid gas just above its melting point, and much greater at the low temperature than that of highly expansive solids like sulphur, which at 40° C. has a value of 0.00019. The following table gives the densities at the temperature of boiling liquid air (-18° C.) and at ordinary temperatures (7° C.), together with the mean coefficient of expansion between these temperatures, in the case of a number of hydrated salts and other substances:

1 The figures within parentheses refer to the number of molecules of water of crystallization.

-18° C. to -38° C. It will be seen from this table that, with the exception of carbonate of soda and chrome alum, the hydrated salts have a coefficient of expansion that does not differ greatly from that of ice at low temperatures. Iodine is a highly expansive body like iodine, and oxalate of methyl has nearly as great a coefficient as paraffin, which is a very expansive solid, as are naphthalene and oxalic acid. The coefficient of sodium mercury is about half of volume of malleable iron, and that of sodium is about the value of mercury at ordinary temperatures. Further details on the subject can be found in the Proc. Roy. Inst. (1895), and Proc. Roy. Soc. (1902).

Density of Gases at Low Temperatures.—The ordinary mode of determining the density of gases may be followed, provided that the glass flask, with its carefully ground stop-cock sealed on, can stand an internal pressure of about five atmospheres, and that all the corrections for change of volume are made. It is necessary to immerse the exhausted flask in boiling oxygen, and then to allow the second gas to enter from a gasometer by opening the stop-cock until the pressure is equalized. The stop-cock being closed, the flask is now taken out of the large oxygen bath and put in the balance-room until its temperature is equalized. It is then weighed against a similar flask used as a counterpoise. Following such a method, it has been found that the weight of 1 litre of oxygen vapour at its boiling point of 90.5° absolute is 4.420 grammes, and therefore the specific volume is 220.82 cc. According to the ordinary gaseous laws, the litre ought to weigh 4.313 grammes, and the specific volume should be 231.82 cc. In other words, the product of this specific volume at the boiling point is diminished by 2.46%. In a similar way the weight of a litre of nitrogen vapour at the boiling point of oxygen was found to be 3.90, and the inferred value for 78° absolute, or its own boiling point, would be 4.51, giving a specific volume of 221.3.

Regenerative Cooling.—One part of the problem being thus solved and a satisfactory device discovered for warding off heat in such vacuum vessels, it remained to arrange some practi- cally efficient method for reducing hydrogen to a temperature sufficiently low for liquefaction. To gain that end, the idea naturally occurred of using adiabatic expansion, not intermit tently, as when gas is allowed to expand suddenly from a high compression, but in a continuous process, and an obvious way of attempting to carry out this condition was to enclose the orifice at which expansion takes place in a tube, so as to obtain a constant stream of cooled gas passing over it. But further consideration of this plan showed that although the gas jet would be cooled near the point of expansion owing to the conversion of a portion of its sensible heat into dynamical energy of the moving gas, yet the heat it thus lost would be restored to it almost
immediately by the destruction of this mechanical energy through friction and its consequent reconversion into heat. Thus the net result would be nil so far as change of temperature through the performance of external work was concerned. But the conditions in such an arrangement resemble that in the experiments of Thomson and Joule on the thermal changes which occur in a gas when it is forced under pressure through a porous plug or narrow orifice, and those experimenters found, as the former of them had predicted, that a change of temperature does take place, owing to internal work being done by the attraction of the gas molecules. Hence the effective result obtained in practice by such an attempt at continuous adiabatic expansion as that suggested above is to be measured by the amount of the "Thomson-Joule effect," which depends entirely on the internal, not the external, work done by the gas. To Linde belongs the credit of having first seen the essential importance of this effect in connexion with the liquefaction of gases by adiabatic expansion, and he was, further, the first to construct an industrial plant for the production of liquid air based on the application of this principle.

The change of temperature due to the Thomson-Joule effect varies in amount with different gases, or rather with the temperature at which the operation is conducted. At ordinary temperatures oxygen and carbonic acid are cooled, while hydrogen is slightly heated. But hydrogen also is cooled if before being passed through the nozzle or plug it is brought into a thermal condition comparable to that of other gases at ordinary temperatures—that is to say, when it is initially cooled to a temperature having the same ratio to its critical point as their temperatures have to their critical points—and similarly the more condensible gases would be heated, and not cooled, by passing through a nozzle or plug if they were employed at a temperature sufficiently above their critical points. Each gas has therefore a point of inversion of the Thomson-Joule effect, and this temperature is, according to the theory of van der Waals, about 6.75 times the critical temperature of the body.

Olczewski has determined the inversion-point in the case of hydrogen, and finds it to be 102.5° absolute, the theoretical critical point being thus about 28.5° absolute.

The cooling effect obtained is small, being for air about 4° C. per atmosphere difference of pressure at ordinary temperatures. But the decrement of temperature is proportional to the difference of pressure and inversely as the absolute temperature, so that the Thomson-Joule effect increases rapidly by the combined use of a lower temperature and greater difference of gas pressure. By means of the "regenerative" method of working, which was described by C.W. Siemens in 1857, developed and extended by Ernest Solvay in 1885, and subsequently utilized by numerous experimenters in the construction of low-temperature apparatus, a practicable liquid air plant was constructed by Linde. The gas which has passed the orifice and is therefore cooled is made to flow backwards round the tube that leads to the nozzle; hence that portion of the gas that is just about to pass through the nozzle has some of its heat abstracted, and in consequence on expansion is cooled to a lower temperature than the first portion. In its turn it cools a third portion in the same way, and so the reduction of temperature goes on progressively until ultimately a portion of the gas is liquefied. Apparatus based on this principle has been employed not only by Linde in Germany, but also by Tripler in America and by Hampson and Dewar in England. The last-named experimenter exhibited in December 1895 a laboratory machine of this kind (fig. 2), which when supplied with oxygen initially cooled to —79° C., and at a pressure of 100-150 atmospheres, began to yield liquid in about a quarter of an hour after starting. The initial cooling is not necessary, but it has the advantage of reducing the time required for the operation. The efficiency of the Linde process is small, but it is easily conducted and only requires plenty of cheap power. When we can work turbines or other engines at low temperatures, so as to effect cooling through the performance of external work, then the economy in the production of liquid air and hydrogen will be greatly increased.

This treatment was next extended to hydrogen. For the reason already explained, it would have been futile to experiment with this substance at ordinary temperatures, and therefore as a preliminary it was cooled to the temperature of boiling liquid air, about —190° C. At this temperature it is still 21 times above its critical temperature, and therefore its liquefaction in these circumstances would be comparable to that of air, taken at +60° C., in an apparatus like that just described. Dewar showed in 1896 that hydrogen cooled in this way and expanded in a regenerative coil from a pressure of 200 atmospheres was rapidly reduced in temperature to such an extent that after the apparatus had been working a few minutes the issuing jet was seen to contain liquid, which was sufficiently proved to be liquid hydrogen by the fact that it was so cold as to freeze liquid air and oxygen into hard white solids. Though with this apparatus, a diagrammatic representation of which is shown in fig. 3, it was now found possible at the time to collect the

![Fig. 2.—Laboratory Liquid Air Machine.](image)

liquid in an open vessel, owing to its low specific gravity and the rapidity of the gas-current, still the general type of the arrangement seemed so promising that in the next two years there was laid down in the laboratories of the Royal Institution a large plant—it weighs 2 tons and contains 3000 ft. of pipe—which is designed on precisely the same principles, although its construction is far more elaborate. The one important novelty, without which it is practically impossible to succeed, is the provision of a device to surmount the difficulty of withdrawing the liquefied hydrogen after it has been made. The desideratum is really a means of forming an aperture in the bottom of a vacuum vessel by which the contained liquid may be run out. For this purpose the lower part of the vacuum vessel (D in fig. 3) containing the jet is modified as shown in fig. 4; the inner vessel is prolonged in a fine tube, coiled spirally, which passes through the outer wall of the vacuum vessel, and thus sufficient elasticity is obtained to enable the tube to withstand without fracture the great contraction consequent on the extreme cold to which it is subjected. Such peculiarly shaped vacuum vessels were made by Dewar's directions in Germany, and have subsequently been supplied to and employed by other experimenters.

With the liquefying plant above referred to liquid hydrogen was for the first time collected in an open vessel on the 10th of May 1898. The gas at a pressure of 180 atmospheres was cooled to −205° C. by means of liquid air boiling in vacuo, and was then passed through the nozzle of the regenerative coil, which was enclosed in vacuum vessels in such a way as to exclude external heat as perfectly as possible. In this way some 20 cc. of the liquid had been collected when the experiment came to a premature end, owing to the nozzle of the apparatus becoming blocked by a dense solid—air-ice resulting from the condensation of the air which was present to a minute extent as an impurity in the hydrogen. This accident exemplifies what is a serious trouble encountered in the production of liquid hydrogen, the extreme difficulty of obtaining the gas in a state of sufficient purity, for the presence of 1% of foreign matters, such as air or oxygen, which are more condensable than hydrogen, is sufficient to cause complete stoppage, unless the nozzle valve and jet arrangement is of special construction. In subsequent experiments the liquid was obtained in larger quantities—on the 13th of June 1901 five liters of it were successfully conveyed through the streets of London from the laboratory of the Royal Institution to the rooms of the Royal Society—and it may be said that it is now possible to produce it in any desired amount, subject only to the limitations entailed by expense. Finally, the reduction of hydrogen to a solid state was successfully undertaken in 1899. A portion of the liquid carefully isolated in vacuum-jacketed vessels was suddenly transformed into a white mass resembling frozen foam, when evaporated under an air-pump at a pressure of 20 or 40 mm. - and subsequently hydrogen was obtained as a clear transparent ice by immersing a tube containing the liquid in this solid foam.

Liquefaction of Helium.—The subjection of hydrogen completed the experimental proof that all gases can be reduced to the liquid and solid states by the aid of pressure and low temperature, at least so far as regards those in the hands of the chemist at the beginning of the last decade of the 19th century. But a year or so before hydrogen was obtained in the liquid form, a substance known to exist in the sun from spectroscopic researches carried out by Sir Edward Frankland and Sir J. Norman Lockyer was shown by Sir William Ramsay to exist on the earth in small quantities. Helium (g.z.), as this substance was named, was found by experiment to be a gas much less condensable than hydrogen. Dewar in 1901 expanded it from a pressure of 80–100 atmospheres at the temperature of solid hydrogen without perceiving the least indication of liquefaction. Olszewksi repeated the experiment in 1905, using the still higher initial compression of 180 atmospheres, but he equally failed to find any evidence of liquefaction, and in consequence was inclined to doubt whether the gas was liquefiable at all, whether in fact it was not a truly "permanent" gas. Other investigators, however, took a different and more hopeful view of the matter. Dewar, for instance (Pres. Address Brit. Assoc., 1902), basing his deductions on the laws established by van der Waals and others from the study of phenomena at much higher temperatures, anticipated that the boiling-point of the substance would be about 5° absolute, so that the liquid would be about four times more volatile than liquid hydrogen, just as liquid hydrogen is four times more volatile than liquid air; and he expressed the opinion that the gas would succumb on being subjected to the process that had succeeded with hydrogen, except that liquid hydrogen, instead of liquid air, evaporating under exhaustion must be employed as the primary cooling agent, and must also be used to surround the vacuum vessel in which the liquid was collected.

Various circumstances combined to prevent Dewar from actually carrying out the operation thus foreshadowed; but the apparatus was justified by the efficiency of the method he indicated practically proved by Dr H. Kamerlingh Onnes, who, working with the splendid resources of the Leiden cryogenic laboratory, succeeded in obtaining helium in the liquid state on the 10th of July 1908. Having prepared 200 litres of the gas (160 litres in reserve) from monazite sand, he cooled it with exhausted liquid hydrogen to a temperature of 15 or 10° abs., and expanded it through a regenerative coil under a pressure of 50 to 100 atmospheres, making use of the most elaborate precautions to prevent influx of heat and securing the absence of less volatile gases that might freeze and block the tubes of the apparatus by including in the helium circuit charcoal cooled to the temperature of liquid air. Operations began at 5:45 in the morning with the preparation of the necessary liquid hydrogen, of which 20 litres were ready by 1:30. The circulation of the helium was started at 4:30 in the afternoon and was continued until the gas had been pumped round the circuit twenty times; but it was not till 7:30, when the last bottle of liquid had been brought into requisition, that the surface of the liquid was seen, by reflection of light from below, standing out sharply like the edge of a knife against the glass wall of the vacuum vessel. Its boiling-point has been determined as being 4° abs., its critical temperature 5°, and its critical pressure not more than three atmospheres. The density of the liquid is found to be 0.015 or about twice that of liquid hydrogen. It could not be solidified even when exhausted under a pressure of 2 mm., which in all probability corresponds to a temperature of 2° abs. (see Communications from the physical laboratory at the University of Leiden, 1908–1909).

The following are brief details respecting some of the more important liquid gases that have become available for study within recent years. (For argon, neon, krypton, &c., see ARGON.)

Liquid Oxygen.—The preparation of volatile transparent liquid oxygen by cooling a faint blue colour. At atmospheric pressure it boils at −181.5° C.; and at a reduced pressure of 1 cm. of mercury its temperature falls to −210° C. At the boiling point it has a density of 1.124 according to Osowskii; of 1.12 according to Robb-Laski; Dewar obtained 1.1375 as the mean of twenty observations by weighing a number of solid substances in liquid oxygen, noting the apparent relative density of the liquid, and thence calculating its real density. Fizeau's values for the coefficients of expansion of the solid being employed. The capacity of a litre of hot oxygen is about two-thirds that of water; it is a non-conductor of electricity, and is strongly magnetic. By its own evaporation it cannot be reduced to the solid state, but exposed to the temperature of liquid hydrogen it is frozen

1 It may be noted that now that the commercial production of oxygen is effected by the liquefaction of air, with separation of its component gases, the question of the physical constitution of liquid oxygen is a matter of the same importance as that of the command large quantities not only of the less volatile constituents, krypton and xenon, but also of the more volatile ones, neon and helium. Roughly a million volumes of air contain 20 volumes of neon and helium, about 15 of the former to 5 of the latter, approximately 1 volume of hydrogen being associated with them, so that in view of the enormous amounts of oxygen that are produced, helium can be obtained in practically any quantity directly from the atmosphere.
LIQUID GASES

into a solid mass, having a pale bluish tint, showing by reflection all the absorption bands of the liquid. It is remarkable that the same absorption bands occur in the expanded gas. Dewar gives the melting-point as 38° absolute, and the density at the boiling-point of hydrogen as 1-4265. The refractive index of the liquid for the D line is 1-0061.

Ozone.—This gas is easily liquefied by the use of liquid air. The liquid obtained is intensely blue, and on allowing the temperature to rise, boils at 21° absolute. According to this, it may be obtained in sulphide of carbon to a faint blue solution. The liquid ozone seems to be more magnetic than liquid oxygen.

Nitrogen forms a transparent colourless liquid, having a density of 0-8042 at its boiling-point. The liquid rapidly assumes an index of refraction and a density of 1-0253. Evaporated under diminished pressure the liquid solidifies at a temperature of −215° C. melting under a pressure of 90 mm. The density of the solid at the boiling-point of hydrogen is 1-0267. As might be expected, the boiling-points of nitrogen and oxygen are different, it might be expected that on the liquefaction of atmospheric air the two elements would appear as two separate liquids. Such, however, is not the case; they come down simultaneously as one homogeneous liquid. Prepared on a large scale, liquid air may contain as much as 50% of oxygen when collected in open vacuum-vessels, but since nitrogen is the more volatile it boils off first, and as the liquid gradually becomes richer in oxygen the temperature at which it boils rises from about −198° C. to about −182° C. At the former temperature it has a density of about 0-910. It is a non-conductor of electricity, and is perfectly transparent, but jelly-like mass, a magma of solid nitrogen containing liquid oxygen, which may indeed be extracted from it by means of a magnet, or by rapid rotation of the vacuum vessel in imitation of an electric mill. The density of the liquid is 1-1075 at a temperature of about 14 mm. is −216° C. At the still lower temperatures attainable by the aid of liquid hydrogen it becomes a white solid, having, like solid oxygen, a faint blue tint. The refractive index of liquid air is 1-0077.

Fluorine, prepared in the free state by Moissan's method of electrolyzing a solution of potassium fluoride in anhydrous hydrofluoric acid, was liquefied in the laboratories of the Royal Institution. In evaporation of the resulting liquid, the gas did not change its state, though it lost much of its chemical activity, and ceased to attack glass. But a very small vacuum formed over the oxygen was sufficient to liquefy the gas; and this may also be the cooling of a temperature of freshly-mad liquid air boiling at atmospheric pressure. Hence the boiling-point is fixed at about −187° C. The liquid is of a clear yellow colour, possessing great mobility. Its density is 1-14, and its capitalizing power is two-thirds that of water. The liquid, when examined in a thickness of 1 cm., does not show any absorption bands, and it is not attracted by a magnet. In liquid hydrogen it is frozen to a white solid, melting at about 47° abs.

Hydrogen is a gas that liquid is in the hands of the chemist, having a density slightly less than 0-07 as compared with water, and being six times lighter than liquid marsh-gas, which is next in order of lightness. One litre weighs only 70 grammes, and 1 gramme of liquid occupies a volume of 1400 times that of water. Its lightness, however, it is easily seen, has a well-defined meniscus and drops well. At its boiling-point the liquid is only 55 times denser than the vapour it is giving off, whereas liquid oxygen in similar proportion is 258 times denser than its vapour, and nitrogen 177 times. Its atomic volume is about 14-3, that of liquid oxygen being 13-7, and that of liquid nitrogen 16-6, at their respective boiling-points. Its latent heat of vaporization about the boiling-point is about 121 gramme-calories, and the latent heat of the liquid hydrogen cannot exceed 16 units, but may be less. Hydrogen appears to have the same specific heat in the liquid as in the gaseous state, about 3-4. Its surface tension is exceedingly low, about one-fifth that of liquid air. It can be liquefied for a temperature of 30° absolute. Hydrogen cannot exist, if the liquid is not less than 0-1° C. above the freezing-point of water.

Its boiling-point at atmospheric pressure is −238° C., while a similar thermometer made with an alloy of rhodium-platinum indicated a value 8 degrees lower. A thermometer of platinum-gold, the first results obtained from the use of a platinum resistance thermometer gave −238° C., while a similar thermometer made with an alloy of rhodium-platinum indicated a value 8 degrees lower. A thermometer of platinum-gold, a platinum-iridium one the result was only −210° C. It was thus evident that electrical resistance thermometers are not to be trusted at these low temperatures, since the laws correlating resistance and temperature are not known for temperatures at and below the boiling-point of hydrogen, though they are certainly not the same as those which hold good higher up the thermometric scale.

The Approach to the Absolute Zero.—The achievement of Kamerlingh Onnes has brought about the realization of a temperature removed only 3° from the absolute zero, and the question naturally suggests itself whether there is any probability of a still closer approach to that point. The answer is that if, as is not impossible, there exists a gas, as yet undiscovered, which has an atomic weight one-half that of helium, that gas, liquefied in turn by the aid of liquid helium, would render that approach possible, though the experimental difficulties of the operation would be enormous and perhaps prohibitive. The results of experiments bearing on this question and of theory based on them are shown in table II. The third column shows the critical temperature of the gas which can be liquefied by continuous expansion through a range of temperatures. The operation being started from the initial temperature shown in the second column, while the fourth column gives the temperature of the resulting liquid. It will be seen that by the use of liquid or solid hydrogen as a cooling agent, it should be possible to liquefy a body having a critical temperature of about 6° to 8° on the absolute scale, and a boiling point of about 4° or 5°, while with the aid of liquid helium at an initial temperature of 3° we could liquefy a body having a critical temperature of 5° and a boiling point of 1°.

It is to be remarked, however, that even so the physicist would not have attained the absolute zero, and he can scarcely hope ever to do so. It is true he would only be a very short distance from it, but it must be remembered that in a thermodynamic sense one degree low on the scale, say at 10° absolute, is equivalent to 36° at the ordinary temperature, and as the experimenter gets to lower and lower temperatures, the difficulties of further advance increase, not in arithmetic but in geometric progression. This is the step between the liquefaction of air and that of hydrogen, thermodynamically and practically, greater than that between the liquefaction of chlorine and that of air, but the number of degrees of temperature that separates
the boiling-points of the first pair of substances is less than half what it is in the case of the second pair. But the ratio of the absolute boiling-points in the first pair of substances is as 1 to 4; whereas in the second pair it is only 1 to 3, and it is this value that expresses the difficulty of the transition.

But though Ultima Thule may continue to mock the physicist’s efforts, he will long find ample scope for his energies in the investigation of the properties of matter at the temperatures placed at his command by liquid air and liquid and solid hydrogen. Indeed, great as is the sentimental interest attached to the liquefaction of these refractory gases, the importance of the achievement lies rather in the fact that it opens out new fields of research and enormously widens the horizon of physical science, enabling the natural philosopher to study the properties and behaviour of matter under entirely novel conditions. We propose to indicate briefly the general directions in which such inquiries have so far been carried on, but before doing so will call attention to the power of absorbing gases possessed by cooled charcoal, which has on that account proved itself a most valuable agent in low temperature research.

**Gas Absorption by Charcoal.**—Felix Fontana was apparently the first to discover that hot charcoal has the power of absorbing gases, and his observations were confirmed about 1770 by Joseph Priestley, to whom he had communicated them. A generation later Theodore de Saussure made a number of experiments on the subject, and noted that at ordinary temperatures the absorption is accompanied with considerable evolution of heat. Among subsequent investigators were Thomas Graham and Stenhousen, Faure and Silberman, and Hunter, the last-named showing that charcoal made from coco-nut exhibits greater absorptive powers than other varieties. In 1874 Tait and Dewar for the first time employed charcoal for the production of high vacua, by using it, heated to a red heat, to absorb the mercury vapour in a tube exhausted by a mercury pump; and thirty years afterwards it occurred to the latter investigator to try how its absorbing powers are affected by cooling it, with the result that he found them to be greatly enhanced. Some of his earlier observations are given in table III., but it must be pointed out that much larger absorptions were obtained subsequently when it was found that the quality of the charcoal was greatly influenced by the mode in which it was prepared, the absorptive power being increased by carbonizing the coco-nut shell slowly at a gradually increasing temperature. The results in the table were all obtained with the same specimen of charcoal, and the volumes of the gases absorbed, both at ordinary and at low temperatures, were measured under standard conditions—at 0° C., and 760 mm. pressure. It appears that at the lower temperature there is a remarkable increase of absorption for every gas, but that the increase is in general smaller as the boiling-points of the various gases are lower. Helium is conspicuous for the fact that it is absorbed to a comparatively slight extent at both the higher and the lower temperature, but in this connexion it must be remembered that, being the most volatile gas known, it is being treated at a temperature which is relatively much higher than the other gases. At 185° (=85° abs.), while hydrogen is at about 4.5 times its boiling-point (20° abs.), helium is at about 20 times its boiling-point (4.5° abs.), and it might, therefore, be expected that if it were taken at a temperature corresponding to that of the hydrogen, i.e. at 4 or 5 times its boiling-point, or say 20° abs., it would undergo much greater absorption. This expectation is borne out by the results shown in table IV., and it may be inferred that charcoal cooled in liquid helium would absorb helium as freely as charcoal cooled in liquid hydrogen absorbs hydrogen. It is found that a given specimen of charcoal cooled in liquid oxygen, nitrogen and hydrogen absorbs about equal volumes of those three gases (about 260 cc. per gramme; and, as the relation between volume and temperature is nearly linear at the lowest portions of either the hydrogen or the helium absorption, it is a legitimate inference that at a temperature of 5° to 6° abs. helium would be as freely absorbed by charcoal as hydrogen is at its boiling-point and that the boiling-point of helium lies at about 5° abs.

The rapidity with which air is absorbed by charcoal at 185° C. and under small pressures is illustrated by table V., which shows the reductions of pressure effected in a tube of 2000 cc. capacity by means of 20 grammes of charcoal cooled in liquid air.

**Charcoal Occlusion Pressures.**—For measuring the gas concentration, pressure and temperature, use may be made of an apparatus of the type shown in fig. 5. A mass of charcoal, E, immersed in liquid air, is employed for the preliminary exhaustion of the McLeod gauge G and of the charcoal C, which is to be used in the actual experiments, and is then sealed of at S. The bulb B is then placed in a large spherical vacuum vessel containing liquid oxygen which can be made to boil at any definite temperature under diminished pressure which is measured by the manometer R. The volume of gas admitted into the charcoal is determined by the burette D and the pipette P, and the corresponding occlusion pressure at any concentration and any temperature below 95° abs. by the gauge G. In presence of charcoal, and for small concentrations, great variations are shown in the relation between the pressure and the concentration of different gases, all at the same temperature. Table VI. gives the comparison between hydrogen and nitrogen at the temperature of liquid air. 25 grammes of charcoal being employed. It is seen that 15 cc. of hydrogen produce nearly the same pressure (0-0645 mm.) as 2500 cc. of nitrogen (0-06172 mm.). This result shows how
LIQUID GASES

Production of High Vacua.—Exceedingly high vacua can be obtained by the aid of liquid gases, with or without charcoal. If a vessel containing liquid hydrogen be freely exposed to the atmosphere, a rain of snow (solid air) at once begins to fall upon the surface of the liquid; similarly, if one end of a sealed tube containing ordinary air be immersed in the liquid, the same thing happens, but since there is now no new supply to take the place of the air that has been solidified and has accumulated in the cooled portion of the tube, the pressure is quickly reduced to something like one-millionth of an atmosphere, and a vacuum is formed of such tenuity that the electric discharge can be made to pass only with difficulty. Liquid air can be employed in the same manner if the tube, before sealing, is filled with some less volatile gas or vapour, such as sulphurous acid, benzol or water vapour. But if a charcoal condenser be used in conjunction with the liquid air it becomes possible to obtain a high vacuum when the tube contains air initially. For instance, in one experiment, with a bulb having a capacity of 300 cc. and filled with air at a pressure of about 1.7 mm. and at a temperature of 15° C., when an attached condenser with 5 grammes of charcoal was cooled in liquid air, the pressure was reduced to 0.0545 mm. of mercury in five minutes, to 0.01032 mm. in ten minutes, to 0.000139 mm. in thirty minutes, and to 0.000047 mm. in sixty minutes. The condenser then being cooled in liquid hydrogen the pressure fell to 0.0000154 mm. in ten minutes, and to 0.0000058 mm. in a further ten minutes when solid hydrogen was employed as the cooling agent, and no doubt, had it not been for the presence of hydrogen and helium in the air, an even greater reduction could have been effected. Another illustration of the power of cooled charcoal to produce high vacua is afforded by a Crookes radiometer. If the instrument be filled with helium at atmospheric pressure and a charcoal bulb attached to it be cooled in liquid air, the vanes remain motionless even when exposed to the concentrated beam of an electric arc lamp; but if liquid hydrogen be substituted for the liquid air rapid rotation at once sets in. When a similar radiometer was filled with hydrogen and the attached charcoal bulb was cooled in liquid air rotation took place, because sufficient of the gas was absorbed to permit motion. But when the charcoal was cooled in liquid hydrogen instead of in liquid air, the absorption increased and consequently the rarefaction became so high that there was no motion when the light from the arc was directed on the vanes. These experiments again perform of an inference as to the boiling-point of helium. A fall of 75% in the temperature of the charcoal bulb, from the boiling-point of air to the boiling-point of hydrogen, reduced the vanes to rest in the case of the radiometer filled with hydrogen; hence it might be inferred that a fall of like amount from the boiling-point of helium would reduce the vanes of the helium radiometer to rest, and consequently that the boiling-point of helium would be about 5° abs.

The vacua obtainable by means of cooled charcoal are so high that it is difficult to determine the pressures by the McLeod gauge, and the radiometer experiments referred to above suggested the possibility of another means of ascertaining such pressures, by determining the pressures below which the radiometer would not spin. The following experiment shows how the limit of pressure can be ascertained by reference to the pressures of mercury vapour which have been very accurately determined through a wide range of temperature. To a radiometer (fig. 6) with attached charcoal bulb B was sealed a tube ending in a small bulb containing a globule of mercury. The radiometer and bulb B were heated, exhausted and repeatedly washed out with pure oxygen gas, and then the mercury was allowed to distil

FIG. 5.

Heat of Oclusion.—In every case when gases are condensed to the liquid state there is evolution of heat, and during the absorption of a gas in charcoal or any other occluding body, as hydrogen in palladium, the amount of heat evolved exceeds that of direct liquefaction. From the relation between occlusion-pressure and temperature at the same concentration, the reaction being reversible, it is possible to calculate this heat evolution. Table VIII. gives the mean molecular latent heats of occlusion resulting from Dewar's experiments for a number of gases, having concentrations in the charcoal as shown. The concentrations were so regulated as to start with an initial pressure not exceeding 3 mm. at the respective boiling-points of hydrogen, nitrogen, oxygen and carbon dioxide.

FIG. 6.
for some time into the charcoal cooled in liquid air. On exposure
to the electric beam the vanes began to spin, but soon ceased
when the bulb A was cooled in liquid air. When, however,
the mercury was warmed by placing the bulb in liquid water,
the vanes began to move again, and in the particular
radiometer used this was found to happen when the
temperature of the mercury had risen to \(-23^\circ\) C.
corresponding to a pressure of about one fifty-millionth
of an atmosphere.

For washing out the radiometer with oxygen the
arrangement shown in fig. 7 is convenient. Here A
is a bulb containing perchlorate of potash, which when
heated gives off pure oxygen; C is again the radiometer
and B the charcoal bulb. The side tube E is for the
purpose of examining the gas given off by minerals like
thorium or the gaseous products of the transformation
of radioactive bodies.

Analytic Uses.—Another important use of liquid
gases is an analytic agent, and for this purpose
liquid air is becoming an almost essential laboratory
reagent. It is one of the most convenient agents for
drying gases and for their purification. If a mixture
of gases be subjected to the temperature of liquid air,
it is obvious that all the constituents that are more
condensable than air will be reduced to liquid, while
those that are less condensable will either remain as
a gaseous residue or be dissolved in the liquid obtained.
The bodies present in the latter may be
separated by fractional distillation, while the
contents of the gaseous residue may be further
differentiated by the air
of still lower temperatures,
such as are obtainable
by liquid hydrogen. An apparatus
such as the following can be used to separate
both the less and the
more volatile gases of
the atmosphere,
former being obtained
from their solution in
liquid air by fractional
distillation at low
pressure and separation of
the condensable part of
the distillate by cooling
in liquid hydrogen, while
the latter are extracted
from the residue of liquid air, after the distillation of the first
fraction, by allowing it to evaporate gradually at a temperature
rising only very slowly.

In fig. 8, A represents a vacuum-jacketed vessel, containing
liquid air; this can be made to boil at reduced pressure and therefore
be lowered in temperature by means of an air-pump, which is
in communication with the vessel through the pipe \(a\). The liquid
boiled away is replenished when necessary from the reservoir \(C\), \(p\)
being a valve, worked by handle \(q\), by which the flow along \(r\) is
regulated. The vessel \(B\), immersed in the liquid air of \(A\),
communicates with the atmosphere by \(a\); hence when the temperature
of \(A\) falls under exhaustion below that of liquid air, the contents
of \(B\) condense, and if the stop-cock \(m\) is kept open, and \(n\) shut, air
from the outside is continuously sucked in until \(B\) is full of liquid,
which contains in solution the whole of the most volatile gases of
the atmosphere which have passed in through \(a\). At this stage of
the operation \(m\) is closed and \(n\) opened, a passage thus being opened
along \(b\) from \(A\) to the remainder of the apparatus seen on the left
side of the figure. Here \(E\) is a vacuum vessel containing liquid
hydrogen, and \(d\) a three-way cock by which communication can be
established either between \(b\) and \(D\), between \(b\) and \(c\), the tube leading
to the sparking-tube \(g\), or between \(D\) and \(c\). If now \(d\) is arranged
so that there is a free passage from \(b\) to \(D\), and the stop-cock \(n\) also
opened, the gas dissolved in the liquid in \(B\), together with some of the
most volatile part of that liquid, quickly distils over into \(D\),
which is at a much lower temperature than \(B\), and some of it con-
denses there in the solid state. When a small fraction of the contents
of \(B\) has thus distilled over, \(d\) is turned so as to close the passage
between \(D\) and \(b\) and open that between \(D\) and \(c\), with the result
that the gas in \(D\) is pumped out by the mercury-pump, shown
diagrammatically at \(F\); along the tube \(c\) (which is immersed in the

![Fig. 7.](image)  
![Fig. 8.](image)  
![Fig. 9.](image)
use the apparatus, stop-cock $d$ is closed and $e$ opened, and gas allowed to pass from the gas-holder into $B$, where it is condensed in the solid form. Stop-cock $e$ then being closed and $d$ opened, gas passes into the exhausted tube $f$, where it is examined with the spectroscope. The vessel $D$ contains liquid air, in which the tube $e$ is immersed in order to condense vapour of mercury which would otherwise pass from the pump into the sparking-tube. The success of the operation of separating all the gases which occur in air and which boil at different temperatures, depends on keeping the temperature of $B$ as low as possible, as will be understood from the following consideration:—

The pressure $p$, of a gas $G$, above the same material in the liquid state, at temperature $T$, is given approximately by the formula

$$\log p = A - B \frac{1}{T},$$

where $A$ and $B$ are constants for the same material. For some other gas $G'$ the formula will be

$$\log p' = A' - B' \frac{1}{T},$$

and

$$\log \frac{p'}{p} = A' - A + B' - B \frac{1}{T}.$$

Now for argon, krypton and xenon respectively the values of $A$ are 67.82, 69.72 and 69.65, and those of $B$ are 339, 496.3 and 669.2; so that for these substances and many others $A - A'$ is always a small quantity, while $B' - B$ is considerable and increases as $T$ diminishes. Hence the ratio of $p$ to $p'$ increases rapidly as $T$ diminishes, and by evaporating all the gases from the solid state and keeping the solid as at low a temperature as possible, the gas that is taken off by the mercurial pump first consists mainly of the substance which has the lowest boiling point, in this case nitrogen, and is succeeded with comparative abruptness by the gas which has the next higher boiling point. Examination of the spectrum in the sparking-tube easily reveals the change from one gas to another, and when that is observed the reservoirs into which the gases are pumped can be changed and the fractions stored separately. Or several sparking-tubes may be arranged so as to form parallel communications between $b$ and $e$, and can be successively sealed off at the desired stages of fractionation.

Analytical operations can often be performed still more conveniently with the help of charcoal, taking advantage of the selective character of its absorption, the general law of which is that the more volatile the gas the less is it absorbed at a given temperature. The following are some examples of its employment for this purpose. If it be required to separate the helium which is often found in the gases given off by a thermoelement, they are subjected to the action of charcoal cooled with liquid air. The result is the absorption of the less volatile constituents, i.e. all except hydrogen and helium. The gaseous residue, with the addition of oxygen, is then sparked, and the water thus formed is removed together with the excess of oxygen, when helium alone remains. Or the separation may be effected by a method of fractionation as described above. To separate the most volatile constituents of the atmosphere an apparatus such as that shown in fig. 10 may be employed. In one experiment with this, when condensed D along with some portion of air. The condenser E is then taken out of the liquid air, heated quickly to $15^\circ$ C. to expel the occluded air and replaced. More air is then passed in, and by repeating the operation several times 50 litres of air can be treated in a short time, supplying sparking-tubes which will show the complete spectra of the volatile constituents of the air.

The less volatile constituents of the atmosphere, krypton and xenon, may be obtained by leading a current of air, purified by passage through a series of tubes cooled in liquid air, through a charcoal condenser also cooled in liquid air. The condenser is then removed and placed in solid carbon dioxide at $-78^\circ$ C. The gas that comes off is allowed to escape, but what remains in the charcoal is got out by heating and exhaustion, the carbon compounds and oxygen are removed and the residue, consisting of nitrogen with krypton and xenon, is separated into its constituents by condensation and fractionation. Another method is to cover a few hundred grammes of charcoal with old liquid air, which is allowed to evaporate slowly in a silvered vacuum vessel; the gases remaining in the charcoal are then treated in the manner described above.

Charcoal enables a mixture containing a high percentage of oxygen to be extracted from the atmosphere. In one experiment 50 grammes of it, after being heated and exhausted were allowed to absorb air at $-18^\circ$ C.; some 5 or 6 litres were taken up in ten minutes, and it then presumably contained air of the composition of the atmosphere, i.e. 20% oxygen and 80% nitrogen, as shown in fig. 11. But when more air was passed over it, the portion that was not absorbed was found to consist of about 98% nitrogen, showing that excess of oxygen was being absorbed, and in the course of a few hours the occluded gas attained a new and apparently definite composition exhibited in fig. 12. When the charcoal containing this mixture was transferred to a vacuum vessel and allowed to warm up slowly, the successive litres of gas when collected and analyzed separately showed the following composition:—

**Colorimetry.**—Certain liquid gases lend themselves conveniently to the construction of a calorimeter, in which the heat in weighed quantities of any substance with which it is desired to experiment may be measured by the quantity of liquid gas they are able to evaporate. One advantage of this method is that a great range of temperature is available when liquid air, oxygen, nitrogen or hydrogen is employed as the calorimetric substance. Another is the relatively large quantity of gas yielded by the evaporation, as may be seen from table IX.

which shows the special physical constants of the various gases that are of importance in colorimetry. In consequence it is easy to detect $\gamma_0$ gram calorie with liquid air and so little as $\frac{1}{4}$ gram calorie with liquid hydrogen.
The apparatus (fig. 13) consists of a large vacuum vessel A, of 2 or 3 litres capacity, containing liquid air, in which is inserted a smaller vacuum vessel B, of 25-30 c.c. capacity, having sealed to it a long narrow tube G that projects above the mouth of A and is held in place by some loosely packed cotton wool. To the top of this tube the test tube C, containing the material under investigation, is connected by a piece of flexible rubber tubing D; this enables C to be tilted so as to throw a piece or pieces of the contained material into the calorimeter. An improved form of this receptacle, attached to B by a flexible tube at D', is shown at C'. In this tube is a wire movable through a cork O and having at its end a hook by means of which a piece of the substance under examination can be pulled up and dropped into B. In the absence of other arrangements the substance is at the temperature of the room, but when lower initial temperatures are desired a vacuum vessel H containing solid carbonic acid, liquid ethylene, air or other gas, can be placed to envelop C or C', or higher temperatures may be obtained by filling the surrounding vessel with vapour of water or other liquids. The gas volatilized in B is conveyed by a side tube E to be collected in a graduated receiver F over water, oil or other liquid. If liquid hydrogen is to be used as the calorimetric substance the instrument must be so modified as to prevent the ordinary atmosphere from entering G, and to that end a current of hydrogen supplied from a Kipp apparatus is arranged to flow continuously through D and E until the moment of making the experiment, when it is cut off by a suitable stop-cock. In this case the outer vessel must contain liquid hydrogen instead of liquid air.

Dewar used pure metallic lead for the purpose of conveying infinitesimal amounts of heat to liquid gas calorimeters of this kind, that metal being selected on the ground of the small variation in its specific heat at low temperatures. He was thus able to determine the latent heats of evaporation of liquid oxygen, nitrogen and hydrogen directly at their boiling points, and he also ascertained the specific heats of a large number of inorganic and organic bodies, and of some gases in the solid state, such as carbon dioxide, sulphurous acid and ammonia. Perhaps his most interesting results were those which showed the variation in the specific heats of diamond, graphite and ice as typical (table X.). With Professor Curie he used both the liquid oxygen and the liquid hydrogen calorimeter for preliminary measurements of the rate at which radium bromide gives out energy at low temperatures. The quantity of the salt available was 0.42 gram, and the thermal evolutions were as follows—

*This is from -18° to -78° in the ice experiment.

The apparent increase of heat evolution at the temperature of liquid hydrogen was probably due to the calorimeter being too small; hydrogen spray was thus carried away with the gas, making the volume of gas too great and inferentially also the heat evolved.

Liquid air and liquid hydrogen calorimeters open up an almost unlimited field of research in the determination of specific heats and other thermal constants, and are certain to become common laboratory instruments for such purposes.

Chemical Action.—By extreme cold chemical action is enormously reduced, though it may not in all cases be entirely abolished even at the lowest temperatures yet attained; one reason for this diminution of activity may doubtless be sought in the fact that in such conditions most substances are solid, that is, in the state least favourable to chemical combination. Thus an electric pile of sodium and carbon ceases to yield a current when immersed in liquid oxygen. Sulphur, iron and other substances can be made to burn under the surface of liquid oxygen if the combustion is properly established before the sample is immersed, and the same is true of a fragment of diamond. Nitric oxide in the gaseous condition combines instantly with free oxygen, producing the highly-coloured gas nitric peroxide, but in the solid condition it may be placed in contact with liquid oxygen without showing any signs of chemical action. If the combination of a portion of the mixture is started by elevation of temperature, then detonation may take place throughout the cooled mass. The stability of endothermic bodies like nitric oxide and ozone at low temperatures requires further investigation. The behaviour of fluorine, which may be regarded as the most active of the elements, is instructive in this respect. As a gas, cooled to -180° C. it loses the power of attacking glass; similarly silicon, borax, carbon, sulphur and phosphorus at the same temperature do not become incandescent in an atmosphere of the gas. Passed into liquid oxygen, the gas dissolves and imparts a yellowish tint to the liquid; if the oxygen has been exposed to the air for some hours, the fluorine produces a white flocculent precipitate, which if separated by filtering deflagrates with violence as the temperature rises. It appears to be a hydrate of fluorine. As a liquid at -210° fluorine attacks turpentine also cooled to that temperature with explosive force and the evolution of light, while the direction of a jet of hydrogen upon its surface is immediately followed by combination and a flash of flame. Even when the point of a tube containing solid fluorine is broken off under liquid hydrogen, a violent explosion ensues.

Photographic Action.—The action of light on photographic plates, though greatly diminished at -180°, is far from being in abeyance; an Eastman film, for instance, remains fairly sensitive at -210°. At the still lower temperature of liquid hydrogen the photographic activity is reduced to about half what it is at that of liquid air; in other words, about 10% of the original sensitivity remains. Experiments carried out with an incandescent lamp, a Röntgen bulb and the ultra-violet spark from magnesium and cadmium, to discover at what distances from the source of light the plates must be placed in order to receive an equal photographic impression, yielded the results shown in table XI.

It appears that the photographic action of both the incandescent lamp and the Röntgen rays is reduced by the temperature of liquid air to 17% of that exerted at ordinary temperatures, while ultra-violet radiation retains only 6%. It is possible that the greater dissipation of the latter by the photographic film at low temperatures than at ordinary ones is due to its
LIQUID GASES

absorption and subsequent emission as a phosphorescent glow, and that if the plate could be developed at a low temperature, it would show no effect, the photographic action taking place subsequently through an internal phosphorescence in the film during the time it is heating up. With regard to the transparency of bodies to the Röntgen radiation at low temperatures, small tubes of the same bore, filled with liquid argon and chlorine, potassium, phosphorus, aluminium, silicon and sulphur, were exposed at the temperature of liquid air (in order to keep the argon and chlorine solid), in front of a photographic plate shielded with a sheet of aluminium, to an X-ray bulb. The sequence of the elements as mentioned represents the order of increasing opacity observed in the shadows. Sodium and liquid oxygen and air, nitrous and nitric oxides, proved much more transparent than chlorine. Tubes of potassium, argon and liquid chlorine showed no very marked difference of density on the photographic plates. It appears that argon is relatively more opaque to the Röntgen radiation than either oxygen, nitrogen or sodium, and is on a level with potassium, chlorine, phosphorus, aluminium and sulphur. This fact may be regarded as supporting the view that the atomic weight of argon is twice its electronegative to hydrogen, since in general the opacity of elements in the solid state increases with the atomic weight.

Phosphorescence.—Phosphorescing sulphides of calcium, which are luminous at ordinary temperatures, and whose emission of light is increased by heating, cease to be luminous if cooled to −80°C. But their light energy is merely rendered latent, not destroyed, by such cold, and they still retain the capacity of taking in light energy at the low temperature, to be evolved again when they are warmed. At the temperature of liquid air many bodies become phosphorescent which do not exhibit the phenomenon at all, or only to a very slight extent, at ordinary temperatures, e.g. ivory, indiarubber, egg-shells, feathers, cotton-wool, paper, milk, gelatine, white of egg, &c. Of definite chemical compounds, the platinocyanides among the inorganic bodies seem to yield the most brilliant effects. Crystals of ammonium platinocyanide, if stimulated by exposure to the ultra-violet radiation of the electric arc—or better still of a mercury vapour lamp in quartz—while kept moistened with liquid air, may be seen in the dark to glow faintly so long as they are kept cold, but become exceedingly brilliant when the liquid air evaporates and the temperature rises. Among organic bodies the phenomenon is particularly well marked with the ketonic compounds and others of the same type. The chloro-, bromo-, iodo-, sulpho- and nitro-compounds show very little effect as a rule. The activity of the alcohols, which is usually considerable, is destroyed by the addition of a little iodine. Coloured salts, &c., are mostly inferior in activity to white ones. When the lower temperature of liquid hydrogen is employed there is a great increase in phosphorescence under light stimulation as compared with that observed with liquid air. The radio-active bodies, like radium, which exhibit self-luminosity in the dark, maintain that luminosity unimpaired when cooled in liquid hydrogen.

Some crystals become for a time self-luminous when placed in liquid hydrogen, because the high electric stimulation due to the cooling causes actual electric discharges between the crystal molecules. This phenomenon is very pronounced with nitrate of uranium and some platinocyanides, and cooling such crystals even to the temperature of liquid air is sufficient to develop marked electrical and luminous effects, which are again observed, when the crystal is taken out of the liquid, during its return to normal temperature. Since both liquid hydrogen and liquid air are good electrical insulators, the fact that electric discharges take place in them proves that the electric potential generated by the cooling must be very high. A crystal of nitrate of uranium indeed gets so highly charged electrically that it refuses to sink in liquid air, although its density is 2.8 times greater, but sticks to the side of the vacuum vessel, and requires for its displacement a distinct pull on the silk thread to which it is attached. Such a crystal quickly removes cloudiness from liquid air by attracting all the suspended particles to its surface, just as a fog is cleared out of air by electrification. It is interesting to observe that neither fused nitrate of uranium nor its solution in absolute alcohol shows any of the remarkable effects of the crystalline state on cooling.

Cohesion.—The physical force known as cohesion is greatly increased by low temperatures. This fact is of much interest in connection with two conflicting theories of matter. Lord Kelvin’s view was that the forces that hold together the ultimate particles of bodies may be accounted for without assuming any other forces than that of gravitation, or any other law than the Newtonian. An opposite view is that the phenomena of cohesion, chemical union, &c., or the general phenomena of the aggregation of molecules, depend on the molecular vibrations as a physical cause (Tolvern Preston, Physics of the Ether, p. 64). Hence at the zero of absolute temperature, this vibrating energy being in complete abeyance, the phenomena of cohesion should cease to exist and matter generally be reduced to an incoherent heap of “cosmic dust.” This second view receives no support from experiment. Atmospheric air, for instance, frozen at the temperature of liquid hydrogen, is a hard solid, the strength of which gives no hint that with a further cooling of some 20 degrees it would crumble into powder. On the contrary, the lower the scale of temperature is descended, the more powerful become the forces which hold together the particles of matter. A spiral of fusible metal, which at ordinary temperatures cannot support the weight of an ounce without being straightened out, will, when cooled to the temperature of liquid oxygen, and so long as it remains in that cooled condition, support several pounds and vibrate like a steel spring. Similarly a bell of fusible metal at −182°C. gives a distinct metallic ring when struck. Balls of iron, lead, tin, ivory, &c., thus cooled, exhibit an increased rebound when dropped from a height; an indiarubber ball, on the other hand, becomes brittle, and is smashed to atoms by a very moderate fall. Tables XII and XIII, which give the mean results of a large number of experiments, show the increased breaking stress gained by metals while they are cooled to the temperature of liquid oxygen.

In the second series of experiments the test-pieces were 2 in. long and were all cast in the same mould. It will be noticed that in the cases of zinc, bismuth and antimony the results appear to be abnormal, but it may be pointed out that it is difficult to get uniform castings of crystalline bodies, and it is probable that by cooling such stresses are set up in some set of cleavage planes as to render rupture comparatively easy. In the case of strong steel springs the rigidity modulus does not appear to be greatly affected by cold, for although a number were examined, no measurable differences could be detected in their elongation under repeated additions of the same load. No quantitative experiments have been made on the cohesive properties of the metals at the temperature of boiling hydrogen (−252°C.), owing to the serious cost that would be involved. A lead wire cooled in liquid hydrogen did not become brittle, as it could be bent backwards and forwards in the liquid.

### Electrical Resistivity.—The first experiments on the conductivity of metals at low temperatures appear to have been
made by Wroblewski (Comptes rendus, cl. 160), and by Cailletet and Bouy (Journ. de phys. 1883, p. 197). The former's experiments were undertaken to test the suggestion made by Clausius that the resistivity of pure metals is sensibly proportional to the absolute temperature; he worked with copper having a conductivity of 68%, and carried out measurements at various temperatures, the lowest of which was that given by liquid nitrogen boiling under reduced pressure. His general conclusion was that the resistivity decreases much more quickly than the absolute temperature, so as to approach zero at a point not far below the temperature of nitrogen evaporating in vacuo. Cailletet and Bouy, using ethylene as the refrigerant, and experimenting at temperatures ranging from 0° C. to -100° C. and -123° C., constructed formulæ intended to give the coefficients of variation in electrical resistance for mercury, tin, silver, magnesium, aluminium, copper, iron and platinum. Between 1892 and 1896 Dewar and Fleming carried out a large number of experiments to ascertain the changes of conductivity that occur in metals and alloys cooled in liquid air or oxygen to -200° C. The method employed was to obtain the material under investigation in the form of a fine regular wire and to wind it in a small coi; this was then plunged in the liquid and its resistance determined. The accompanying chart (fig. 14) gives the results in a compendious form, the temperatures being expressed not in degrees of the ordinary air-thermometer scale, but in platinum degrees as given by one particular platinum resistance thermometer which was used throughout the investigation. A table showing the value of these degrees in degrees centigrade according to Dickson will be found in the Phil. Mag. for June 1898, p. 527; to give some idea of the relationship, it may be stated here that -100° of the platinum thermometer = -94.2° C., -150° plat. = -140°-76° C., and -200° plat. = -185° 53° C. In general, the resistance of perfectly pure metals was greatly decreased by cold — so much so that, to judge by the course of the curves on the chart, it appeared probable that at the zero of absolute temperature resistance would vanish altogether and all pure metals become perfect conductors of electricity. This conclusion, however, has been rendered very doubtful by subsequent observations by Dewar, who found that with the still lower temperatures attainable with liquid hydrogen the increases of conductivity became less for each decrease of temperature, until a point was reached where the curves bent sharply round and any further diminution of resistance became very small; that is, the conductivity remained finite. The reduction in resistance of some of the metals at the boiling point of hydrogen is very remarkable. Thus copper has only 1+5th, gold 9+5th, platinum 3+th to 1+th, silver 2+th the resistance at melting ice, but iron is only reduced to 4th part of the same initial resistance. Table XIV. shows the progressive decrease of resistance for certain metals and one alloy as the temperature is lowered from that of boiling water down to that of liquid hydrogen boiling under reduced pressure: it also gives the "vanishing temperature," at which the conductivity would become perfect if the resistance continued to decrease in the same ratio with still lower temperatures, the values being derived from the extrapolation curves of the relation between resistance and temperature, according to Callendar and Dickson. It will be seen that many of the substances have actually been cooled to a lower temperature than that at which their resistance ought to vanish.

In the case of alloys and impure metals, cold brings about a much smaller decrease in resistivity, and the continuations of the curves at no time show any sign of passing through the zero point. The influence of the presence of impurities in minute quantity is strikingly shown in the case of bismuth. Various samples of the metal, prepared with great care by purely chemical methods, gave in the hands of Dewar and Fleming some very anomalous results, appearing to reach at -80° C. a maximum of conductivity, and thereafter to increase in resistivity with decrease of temperature. But when the determinations were carried out on a sample of really pure bismuth prepared electrolytically, a normal curve was obtained corresponding to that given by other pure metals. As to alloys, there is usually some definite mixture of two pure metals which has a maximum resistivity, often greater than that of either of the constituents. It appears too that high, if not the highest, resistivity corresponds to possible chemical compounds of the two metals employed, e.g. platinum 33 parts with silver 66 parts = PtAg; iron 80 with nickel 20 = FeNi; platinum 80 with iridium 20 = IrPt; and

---

**LIQUID GASES**

---

![Graph](image-url)
for their resistivity steadily increases with cold. The thermo-electric properties of metals at low temperatures are discussed in the article THERMOELECTRICITY.

**Magnetic Phenomena.**—Low temperatures have very marked effects upon the magnetic properties of various substances. Oxygen, long known to be slightly magnetic in the gaseous state, is powerfully attracted in the liquid condition by a magnet, and the same is true, though to a less extent, of liquid air, owing to the proportion of liquid oxygen it contains. A magnet of ordinary carbon steel has its magnetic moment temporarily increased by cooling, that is, after it has been brought to a permanent magnetic condition ("aged"). The effect of the first immersion of such a magnet in liquid air is a large diminution in its magnetic moment, which decreases still further when it is allowed to warm up to ordinary temperatures. A second cooling, however, increases the magnetic moment, which is again decreased by warming, and after a few repetitions of this cycle of cooling and heating the steel is brought into a condition such that its magnetic moment at the temperature of liquid air is greater by a constant percentage than it is at the ordinary temperature of the air. The increase of magnetic moment seems then to have reached a limit, because on further cooling to the temperature of liquid hydrogen hardly any further increase is observed. The percentage differs with the composition of the steel and with its physical condition. It is greater, for example, with a specimen tempered very soft than it is with another specimen of the same steel tempered glass hard. Aluminium steels show the same kind of phenomena as carbon ones, and the same may be said of chrome steels in the permanent condition, though the effect of the first cooling with them is a slight increase of magnetic moment. Nickel steels present some curious phenomena. When containing small percentages of nickel (e.g. 0.4 or 3-82%), they behave under changes of temperature much like carbon steel. With a sample containing 7.65% of the phenomena after the permanent state had been reached were similar, but the first cooling produced a slight increase in magnetic moment. But steels containing 18-64 and 29% of nickel behaved very differently. The result of the first cooling was a reduction of the magnetic moment, to the extent of nearly 50% in the case of the former. Warming again brought about an increase, and the final condition was that at the temperature of liquid air the magnetic moment was always less than at ordinary temperatures. This anomaly is all the more remarkable in that the behaviour of pure nickel is normal, as also appears to be generally the case with soft and hard iron. Silicon, tungsten and manganese steels are also substantially normal in their behaviour, although there are considerable differences in the magnitudes of the variations they display (Proc. Roy. Soc. 1x. 57 et seq.; also "The Effect of Liquid Air Temperatures on the Mechanical and Other Properties of Iron and its Alloys," by Sir James Dewar and Sir Robert Hadfield, Id. lxiv. 326-336).

Low temperatures also affect the permeability of iron, i.e. the degree of magnetization it is capable of acquiring under the influence of a certain magnetic force. With fine Swedish iron, carefully annealed, the permeability is slightly reduced by cooling to -185° C. Hard iron, however, in the same circumstances suffers a large increase of permeability. Unhardened steel pianoforte wire, again, behaves like soft annealed iron. As to hysteresis, low temperatures appear to produce no appreciable effect in soft iron; for hard iron the observations are indecisive.

**Biological Research.**—The effect of cold upon the life of living organisms is a matter of great intrinsic interest as well as of wide theoretical importance. Experiment indicates that moderately high temperatures are much more fatal, at least to the lower forms of life, than are exceedingly low ones. Professor M'Kendrick froze for an hour at a temperature of -182° C. samples of meat, milk, &c., in sealed tubes; when these were opened, after being kept at blood-heat for a few days, their contents were found to be quite putrid. More recently some more elaborate tests were carried out at the Jenner (now Lister) Institute of Preventive Medicine on a series of typical bacteria. These were exposed to the temperature of liquid air for twenty hours, but their vitality was not affected, their functional activities remained unimpaired and the cultures which they yielded were normal in every respect. The same result was obtained when liquid hydrogen was substituted for air. A similar persistence of life has been demonstrated in seeds, even at the lowest temperatures; they were frozen for over 100 hours in liquid air at the instance of Messrs Brown and Escombe, with no other effect than to afflect their protoplasm with a certain inertness, from which it recovered with warmth. Subsequently commercial samples of barley, peas and vegetable-marrow and mustard seeds were literally steeped for six hours in liquid hydrogen at the Royal Institution, yet when they were sown by Sir W. T. Hilsdon Dyer at Kew in the ordinary way, the proportion in which germination occurred was no smaller than with other batches of the same seeds which had suffered no abnormal treatment. Mr Harold Swinbank has found that exposure to liquid air has little or no effect on the vitality of the tubercle bacillus, although by very prolonged exposures its virulence is modified to some extent; but alternate exposures to normal and very cold temperatures do have a decided effect both upon its vitality and its virulence. The suggestion once put forward by Lord Kelvin, that life may in the first instance have been conveyed to this planet on a meteorite, has been objected to on the ground that any living organism would have been killed before reaching the earth by its passage through the intense cold of interstellar space; the above experiments on the resistance to cold offered by seeds and bacteria show that this objection at least is not fatal to Lord Kelvin's idea.

At the Lister Institute of Preventive Medicine liquid air has been brought into use as an agent in biological research. An inquiry into the intracellular constituents of the typhoid bacillus, initiated under the direction of Dr Allan Macfadyen, necessitated the separation of the cell-plasma of the organism. The method at first adopted for the disintegration of the bacteria was to mix them with silver-sand and churn the whole up in a closed vessel in which a series of horizontal vanes revolved at a high speed. But certain disadvantages attached to this procedure, and accordingly some means was sought to do away with the sand and triturate the bacillus per se. This was found in liquid air, which, as had long before been shown at the Royal Institution, has the power of reducing materials like grass or the leaves of plants to such a state of brittleness that they can easily be

powdered in a mortar. By its aid a complete trituration of the typhoid bacilli has been accomplished at the Jenner Institute, and the same process, already applied with success also to yeast cells and animal cells, is being extended in other directions.

**Industrial Applications.**—While liquid air and liquid hydrogen are being used in scientific research to an extent which increases every day, their applications to industrial purposes are not so numerous. The temperatures they give use as simple refrigerants are much lower than are generally required industrially, and such cooling as is needed can be obtained quite satisfactorily, and far more cheaply, by refrigerating machinery employing more easily condensable gases. Their use as a source of motive power, again, is impracticable for any ordinary purposes, on the score of inconvenience and expense. Cases may be conceived of in which, for special reasons, it might prove advantageous to use liquid air, vaporized by heat derived from the surrounding atmosphere, to drive compressed-air engines, but any advantage so gained would certainly not be one of cheapness. No doubt the power of a waterfall running to waste might be temporarily conserved in the shape of liquid air, and thereby turned to useful effect, but, in the direction of air to the liquid state, which involves the expenditure of a very large amount of energy, and it is not possible even to recover all that expended energy during the transition of the material back to the gaseous state. Hence to suggest that by using liquid air in a motor more power can be developed than is expended in producing the liquid air by which the motor is worked, is to propound a fallacy worse than perpetual motion, since such a process would have an efficiency of more than 100%. Still, in conditions where economy is of no account, liquid air might perhaps, with effectively isolated storage, be utilized as a motive power, e.g. to drive the engines of submarine boats and at the same time provide a supply of oxygen for the crew; even without being used in the engines, liquid air or oxygen might be found a convenient form in which to store the air necessary for respiration in such vessels. But a use to which liquid air machines have already been put to a large extent is for obtaining oxygen from the atmosphere. Although when air is liquefied the oxygen and nitrogen are condensed simultaneously, yet owing to its greater volatility the latter boils off the more quickly of the two, so that the remaining liquid becomes gradually richer and richer in oxygen. The fractional distillation of liquid air is the method now universally adopted for the preparation of oxygen on a commercial scale, while the nitrogen simultaneously obtained is used for the production of cyanamide, by its action on carbide of calcium. An interesting though minor application of liquid oxygen, or liquid air from which most of the nitrogen has evaporated, depends on the fact that if it be mixed with powdered charcoal, or finely divided organic bodies, it can be made by the aid of a detonator to explode with a violence comparable to that of dynamite. This explosive, which might properly be called an emergency one, has the disadvantage that it must be prepared on the spot where it is to be used and must be fired without delay, since the liquid evaporates in a short time and the explosive power is lost; but, on the other hand, if a charge fails to go off it has only to be left a few minutes when it can be withdrawn without any danger of accidental explosion.

For further information the reader may consult W. L. Haldin, *Rise and Development of the Alcoholic Liquors* (New York, 1890), and Lefèvre, *La Liquefaction des gas et ses applications*; also the article Asses* on Gases. But the literature of liquid gases is mostly contained in scientific periodicals and the proceedings of learned societies, e.g. by W. Ramsay and W. Whelpley, *Liquefaction of oxygen and nitrogen may be found in the Comptes rendus, vols. xcvii.-cxi., and there are important memoirs by the former on the relations between the gaseous and liquid states and on the electric processes taking place in liquid air, in the Journal de Physique, 1892, and xcvii.; his pamphlet *Comme l’air a été liquéfie* (Paris, 1885) should also be referred to. For Dewar’s work, see *Proc. Roy. Inst. from 1878 onwards, including “Solid Hydrogen,” (1900); “Liquid Hydrogen,” (1904); “New Low Temperature Phenomena” (1905); “Liquid Air and Charcoal at Low Temperatures” (1906); “Studies in High Vacuum and Helium at Low Temperatures” (1907); also “The Nadi of Temperature and Allied Problems” (Bakerian Lecture), *Proc. Roy. Soc. (1901)and the Presidential Address to the British Association (1902). The researches of Fleming and Dewar on the electrical and magnetic properties of substances at low temperatures are described in *Proc. Roy. Soc. vol. lxix., and Proc. Roy. Inst. (1896); see also “Electrical Resistance of Pure Metals, Alloys and Non-Metals, and the Liquefaction of Oxygen,” *Phil. Mag. vol. xxxiv. (1892); “Electrical Resistance of Metals and Alloys at Temperatures approaching the Absolute Zero,” *ibid. vol. xxxvii. (1893); “Thermoelectric Forces of Metals and Alloys being thermal variations in the temperature of boiling-point of Liquid Air,” *ibid. vol. xl. (1895); and papers on the dielectric constants of various substances at low temperatures in *Proc. Roy. Soc. vol. lxxii. and lxiii.* Optical and spectroscopic work on liquid hydrogen by Dewar and the liquid gases is described in *Proc. Roy. Soc. vol. xxxiv. (1892), xxxvii. (1893), xxxviii. (1894) and xl. (1895); for papers by the same authors on the separation and spectroscopic examination of the most volatile and least volatile constituents of atmospheric air, see *Roy. Soc. Proc., 1894-1895.* The influence of very low temperatures on the germinative power of seeds is given by H. T. Brown and F. Escombe in *Proc. Roy. Soc. vol. lxii., and by Sir W. Thesiger Dyer, *ibid. vol. lxv., and their effect on bacteria is discussed by A. Macalduen, *ibid. vol. lxxii., and lxxxii.* (J. Dw.)

**Liquorice.** The hard and semi-vitreous sticks of paste, black in colour and possessed of a sweet somewhat aromatic taste, known as liquorice paste or black sugar, are the impissated juice of the roots of a leguminous plant, *Glycyrhiza glabra*, the *radix glycyrrhiza* of the pharmacopoeia. The plant is cultivated throughout the warmer parts of Europe, especially on the Mediterranean shores, and to some extent in Louisiana and California. The roots for use are obtained in lengths of 3 or 4 ft., varying in diameter from $\frac{1}{2}$ to 1 in.; they are soft, flexible and fibrous, and internally of a bright yellow colour, with a characteristic, sweet pleasant taste. To this sweet taste of its root the plant owes its generic name *Glycyrhiza* (γλυκ'ρης, the sweet-root), of which the word liquorice is a corruption. The roots contain grape-sugar, starch, resin, asparagine, malic acid and the glucoside glycyrrhizin, $C_4\_H_8\_O_3$, a yellow amorphous powder with an acid reaction and a distinctive bitter-sweet taste. On hydrolysis, glycyrrhizin yields glucose and glycyrrhetin.

Stick liquorice is made by crushing and grinding the roots to a pulp, which is boiled in water over an open fire, and the decoction separated from the solid residue of the root is evaporated till a sufficient degree of concentration is attained, after which, on cooling, it is rolled into the form of sticks or other shapes for the market. The preparation of the juice is a widely extended industry along the Mediterranean coasts; but the quality best appreciated in the United Kingdom is made in Calabria, and sold under the names of Solazzi and Corigliano juice. Liquorice enters into the composition of many elixirs and liqueurs, and is used in counter-irritant preparations; and in the form of aromatic syrups and elixirs it has a remarkable effect in masking the taste of nauseous medicines.

**Liquor Laws.** In most Western countries the sale of alcoholic liquor is regulated by law. The original and principal object is to check the evils arising from the immoderate use of such liquor, in the interest of public order, morality and health; a secondary object is to raise revenue from the traffic. The form and the stringency of the laws passed for these purposes vary very widely in different countries according to the habits of the people and the state of public opinion. The evils which it is sought to check are of course far greater than in others. Generally speaking they are greater in northern countries and cold and damp climates than in southern and more sunny ones. Climate has a marked influence on diet for physiological reasons over which we have no control. The fact is attested by universal experience and is perfectly natural and inevitable, though usually ignored in those international comparisons of economic conditions and popular customs which have become so common. It holds good both of food and drink. The inhabitants of south Europe are much less given to alcoholic excess than those of central Europe, who again are more temperate than those of the north. There is even a difference between localities so near together as the east and west of Scotland. The chairman of the Prison Commissioners pointed out before a British royal commission in the year 1897 the greater prevalence of drunkenness in the western half, and attributed it in part to the dampness of the climate on the western coast. But race also has an influence. The British carry the habit of drinking wherever they go, and their colonial
LIQUOR LAWS

[UNITED KINGDOM]

descendants retain it even in hot and dry climates. The Slav peoples and the Magyars in central Europe are much more intolerant than the Teutonic and Latin peoples living under similar climatic conditions. These natural differences lead, in accordance with the principle discerned and enunciated by Montesquieu, to the adoption of different laws, which vary with the local conditions. But social laws of this character also vary with the state of public opinion, not only in different countries but in the same country at different times. The result is that the subject is in a state of incessant flux. There are not only many varieties of liquor laws, but also frequent changes in them, and new experiments are constantly being tried. The general tendency is towards increased stringency, not so much because the evils increase, though that happens in particular places at particular times, as because public opinion moves broadly towards increasing condemnation of excess and increasing reliance on legislative interference. The first is due partly to a general process of refining manners, partly to medical influence and the growing attention paid to health; the second to a universal tendency which seems inherent in democracy.

Liquor laws may be classified in several ways, but the most useful way for the present purpose will be to take the principal methods of conducting the traffic as they exist, under four main headings, and after a brief explanation give some account of the laws in the principal countries which have adopted them. The four methods are: (1) licensing or commercial sale for private profit under a legal permit; (2) sale by authorized bodies not for private profit, commonly known as the Scandinavian or company system; (3) state monopoly; (4) prohibition. It is not a scientific classification, because the company system is a form of licensing and prohibition is no sale at all; but it follows the lines of popular discussion and is more intelligible than one of a more technical character would be. All forms of liquor legislation deal mainly with retail sale, and particularly with the ale-houses which also capture "disinterested management," is adopted in Sweden and Norway; and the principle has been applied in a modified form in England and Finland by the operation of philanthropic societies which, however, have no monopoly but are on the same legal footing as ordinary traders.

1. Licensing.—This is by far the oldest and the most widely adopted method; it is the one which first suggests itself in the natural course of things. Men begin by making and selling a thing without let or hindrance to please themselves. Then objections are raised, and when they are strong or general enough the law interferes in the public interest, at first mildly; it says in effect—"This must not go on in this way or to this extent; there must be some control, and permission will only be given to duly authorized persons. Such persons are licensed or permitted to carry on the traffic under conditions, and there is obviously room for infinite gradations of strictness in granting permission and infinite variety in the conditions imposed. The procedure may vary from mere notification of the intention to open an establishment up to a rigid and minutely detailed system of annual licensing laid down by the law. But in all cases, even when mere notification is required, the governing authority has the right to refuse permission or to withdraw it for reasons given, and so it retains the power of control. At the same time holders of the permission may be compelled to pay for the privilege and so contribute to the public revenue. The great merit of the licensing system is its perfect elasticity, which permits adjustment to all sorts of conditions and to the varying demands of public opinion. It is in force in the United Kingdom, which first adopted it, in most European countries, in the greater part of North America, including both the United States and Canada, in the other British dominions and elsewhere.

2. The Scandinavian or Company System.—The principle of this method is the elimination of private profit on the ground that it removes an incentive to the encouragement of excessive drinking. A monopoly of the sale of liquor is entrusted to a body of citizens who have, or are supposed to have, no personal interest in it, and the profits are applied to public purposes. The system is also called "disinterested management," is adopted in Sweden and Norway; and the principle has been applied in a modified form in England and Finland by the operation of philanthropic societies which, however, have no monopoly but are on the same legal footing as ordinary traders.

3. State Monopoly.—As the name implies, this system consists in retaining the liquor trade in the hands of the state, which thus secures all the profit and is at the same time able to exercise complete control. It is adopted in Russia, in certain parts of the United States and, in regard to the wholesale trade, in Switzerland.

4. Prohibition.—This may be general or local; in the latter case it is called "local option" or "local veto." The sale of liquor is made illegal in the hope of preventing drinking altogether or of diminishing it by making it more difficult. General prohibition has been tried in some American states, and is still in force in a few; it is also applied to native races, under civilized rule, both in Africa and North America. Local prohibition is widely in force in the United States, Canada and Australasia, Sweden and Norway. In certain areas in other countries, including the United Kingdom, the sale of liquor is in a sense prohibited, not by the law, but by the owners of the property who refuse to allow any public-houses. Such cases have nothing to do with the law, but they are mentioned here because reference is often made to them by advocates of legal prohibition.

THE UNITED KINGDOM

England has had a very much longer experience of liquor legislation than any other country, and the story forms an introduction necessary to the intelligent comprehension of liquor legislation in general. England adopted a licensing system in 1551, and has retained it, with innumerable modifications, ever since. The English were notorious for hard drinking for centuries before licensing was adopted, and from time to time sundry efforts had been made to check it, but what eventually compelled the interference of the law was the growth of crime and disorder associated with the public-houses towards the end of the 15th century. Numbers of men who had previously been engaged in the civil wars or on the establishment of feudal houses were thrown out of their occupations and took themselves to the towns, particularly London, where they frequented the ale-houses, "dicing and drinking," and lived largely on violence and crime. An act was passed in 1495 against vagabonds and unlawful games, whereby justices of the peace were empowered to "put away common ale-selling in towns and places where they should think convenient and to take sureties of keepers of ale-houses in their good behaviour." That was the beginning of statutory control of the trade. The act clearly recognized a connexion between public disorder and public-houses. The latter were ale-houses, for at that time ale was the drink of the people; spirits had not yet come into common use, and wine, the consumption of which on the premises was prohibited in 1552, was only drunk by the wealthier classes.

Early History of Licensing.—The act of 1551-1552, which introduced licensing, was on the same lines but went further. It conferred the power of suppressing common ale-selling, and enacted that no one should be allowed to keep a common ale-house or "tippling" house without obtaining the permission of the justices in open session or of two of their number. It further "directed that the justices should take from the persons whom they licensed such bond and surety by recognisance as they should think convenient, and empowered them in quarter session to inquire into and try breaches by licensed persons of the conditions of their recognisances and cases of persons keeping ale-houses without licences and to punish the offenders" (Bonham Carter, Royal Commission on Liquor Licensing Laws, vol. iii.). This act embodied the whole principle of licensing, and the object was clearly stated in the preamble: "For as much as intolerable harms and troubles to the commonwealth of this realm doth daily grow and increase through such abuses and disorders as are had and used in common ale-houses and other places called tippling houses." The evil was not due entirely to the use of alcoholic liquor but to the fact that these houses, being public-houses, were the resort of idle and disorderly characters. The distinction should be borne in mind.

The act seems to have been of some effect, for no further legislation was attempted for half a century, though there is
abundant evidence of the imtemperate habits of all classes. Mr Bonham Carter (loc. cit.) observes:—

"The recognisances referred to in the act were valuable instruments for controlling the conduct of ale-house keepers. The justices, in exercise of their discretion, required the recognisances to contain such conditions for the management and good order of houses as they thought fit. In this way, set regulars came into existence, many of which were subsequently embodied in acts of Parliament. In some counties general rules were drawn up, which every ale-house keeper was bound to observe."

It is interesting to note that among the conditions laid down about this time were the following: Closing at 9 P.M. and during divine service on Sunday; in some cases complete closing on Sunday except to travellers; the licence-holder to notify to the constable all strangers staying for more than a night and not to permit persons to continue drinking or tippling; prohibition of unlawful games, receiving stolen goods and harbouring bad characters; the use of standard measures and prices fixed by law. There was, however, no uniformity of practice in these respects until the 17th century, when an attempt was made to establish stricter and more uniform control by a whole series of acts passed between 1663 and 1627. The evils which it was sought to remedy by these measures were the existence of unlicensed houses, the use of ale-houses for mere drinking and the prevalence of disorder. It was declared that the ancient and proper use of inns and ale-houses was the refreshment and lodging of travellers, and that they were not meant for "entertainment and harbouring of lewd and idle people to spend and consume their money and their time in lewd and drunken manner." Regulations were strengthened for the suppression of unlicensed houses, licences were made annual, and the justices were directed to hold a special licensing meeting once a year (1618). Penalties were imposed on innkeepers for permitting tippling, and also on tipplers and drunkards (1625). In 1634 licensing was first applied to Ireland. Later in the century heavy penalties were imposed for adulteration.

The next chapter in the history of licensing has to do with spirits, and is very instructive. Spirits were not a native product like beer; brandy was introduced from France, gin from the Netherlands and whisky from Ireland; but down to the year 1690 the consumption was small. The home manufacture was strictly limited, and high duties on imported spirits rendered them too dear for the general public unless smuggled. Consequently the people had not acquired the taste for them. But in 1690 distilling was thrown open to any one on the payment of very trifling duties, spirits became extremely cheap and the consumption increased with great rapidity. Regulation of the retail traffic was soon found to be necessary, and by an act passed in 1700-1701, the licensing requirements already existing for ale-house keepers were extended to persons selling distilled liquors for consumption on the premises. A new class of public-houses in the shape of spirit bars grew up. In the year 1732 a complete and detailed survey of all the streets and houses in London was carried out by William Maitland, F.R.S. Out of a total of 95,658 houses he found the following: brew-houses 171, inns 971, taverns 447, ale-houses 5975, brandy-shops 8659, total number of licensed houses for the retail sale of liquor 15,388, of which considerably more than one-half were spirit bars. The population was about three-quarters of a million. About one house in every six was licensed at this time, and that in spite of attempts made to check the traffic by restrictive acts passed in 1728-1729. The physical and moral evils caused by the excessive consumption of spirits were fully recognized; an additional duty of 5s. a gallon was placed on the distiller, and retailers were compelled to take out an excise licence of £29 per annum. The object was to make spirits dearer and therefore less accessible. At the same time, with a view to lessening the number of houses, the licensing procedure of the justices was amended by the provision that licences should only be granted at a general meeting of the justices acting in the division where the applicant resided, thus abolishing the power conferred by the original licensing act, of any two justices to grant a licence. This change, effected in 1729, was a permanent improvement, though it did not prevent the existence of the prodigious numbers of houses recorded by Maitland in 1732. The attempt to make spirits dearer by high excises duties, on the other hand, was adjudged a failure because it led to illicit trade, and the act of 1728 was repealed in 1732. But the evil was so glaring that another and more drastic attempt in the same direction was made in 1736, when the famous Gin Act was passed in response to a petition presented to parliament by the Middlesex magistrates, declaring "that the drinking of geneva and other distilled waters had for some years past greatly increased; that the constant and excessive use thereof had destroyed thousands of His Majesty's subjects; that great numbers of others were by its use rendered unfit for useful labour, debauched in morals and drawn into all manner of vice and wickedness."

The retailing of spirits in quantities of less than 2 gallons was made subject to a licence costing £50 and the retailer had also to pay a duty of 20s. on every gallon sold. This experiment in "high licensing" was a disastrous failure, though energetic attempts were made to enforce it by wholesale prosecutions and by strengthening the regulations against evasion. Public opinion was inflamed against it, and the attempt was abandoned by the executive and an enormous increase of consumption through illicit channels. The consumption of spirits in England and Wales nearly doubled between 1733 and 1742, and the state of things was so intolerable that after much controversy the high duties were repealed in 1742 with the object of bringing the trade back into authorized channels; the cost of a licence was reduced from £50 to £1 and the retail duty from 20s. to 1d. a gallon.

This period witnessed the high-water mark of intemperance in England. From various contemporary descriptions it is abundantly clear that the state of things was incomparably worse than anything in modern times, and that women, whose participation in the practice of drinking and frequenting public-houses is recorded by writers in the previous century, were affected as well as men. The experience is particularly instructive because it includes examples of excess and deficiency of opportunities and the ill effects of both on a people naturally inclined to indulgence in drink. It was followed by more judicious action, which showed the adaptability of the licensing system and the advantages of a mean between laxity and severity. Between 1743 and 1753 acts were passed which increased control in a moderate way and proved much more successful than the previous measures. The retail licence duty was moderately raised and the regulations were amended and made stricter. The class of houses eligible for licensing was for the first time taken into account, and the retailling of spirits was only permitted on premises assessed for rates and, in London, of the annual value of £10; justices having an interest in the trade were excluded from licensing functions. Another measure which had an excellent effect made "tippling" debts—that is, small public-houses debts incurred for spirits—irrecoverable at law. The result of these measures was that consumption diminished and the class of houses improved. At the same time (1753) the general licensing provisions were strengthened and extended. The distinction between new licences and the renewal of old ones was for the first time recognized; applicants for new licences in country districts were required to produce a certificate of character from the clergy, overseers and church-wardens or from three or four householders. The annual licensing sessions were made statutory, and the consent of a justice was required for the transfer of a licence from one person to another during the term for which it was granted. Penalties for infringing the law were increased, and the licensing system was extended to Scotland (1755-1756). With regard to wine, it has already been stated that consumption on the premises was forbidden in 1552, and at the same time the retail sale was restricted to towns of some importance and the number of retailers, who had to obtain an appointment from the corporation or the justices, was strictly limited. In 1660 consumption on the premises was permitted under a Crown (excise) licence, good for a variable term of years; in 1756 this was changed to an annual excise licence of fixed
LIQUOR LAWS [UNITED KINGDOM]

amount, and in 1792 wine was brought under the same jurisdiction of the justices as other liquors.

It is clear from the foregoing that a great deal of legislation occurred during the 18th century, and that by successive enactments, particularly about the middle of the century, the licensing system gradually became adjusted to the requirements of the time and took a settled shape. The acts then passed still form the basis of the law. In the early part of the 19th century another period of legislative activity set in. A parliamentary inquiry into illicit trade in spirits took place in 1821, and in 1828 important acts were passed amending and consolidating the laws for England and for Scotland; in 1833 a general Licensing Act was passed for Ireland. These are still the principal acts, though they have undergone innumerable amendments and additions. The English act of 1828 introduced certain important changes. A licence from the justices was no longer required for the sale of liquor for consumption off the premises, and the power of the justices to suppress public-houses at their discretion (apart from the annual licensing), which they had possessed since 1795, was taken away. The removal of this power, which had long been obsolete, was the natural corollary of the development of the licensing system, its greater stringency and efficiency and the increase of duties imposed on the trade. Men on whom these obligations were laid, and who were freshly authorized to carry on the business every year, could not remain liable to summary deprivation of the privileges thus granted and paid for.

The justices had absolute discretion to withhold licences from an applicant whether new or old; but an appeal was allowed to quarter sessions against refusal and also against conviction for offences under the act. The main points in the law at this time were the following. The sale of alcoholic liquors for consumption on the premises was forbidden under penalties except to persons authorized according to law by the justices. Licences were granted for one year and had to be renewed annually. The justices held a general meeting each year at a specified time for the purpose of granting licences; those peculiarly interested in the liquor trade were disqualified. The licence contained various provisions for regulating the conduct of the house and maintaining order, but closing was only required during the hours of divine service on Sunday. Applicants for new licences and for the transfer of old ones (granted at a special sessions of the justices) were required to give notice to the local authorities and to post up notices at the parish church and on the house concerned.

Excise Licences.—It will be convenient at this point to explain the relation between that part of the licensing system which is concerned with the conduct of the traffic and lies in the jurisdiction of the justices and that part which has to do with taxation or revenue. The former is the earlier and more important branch of legislative interference; we have traced its history from 1495 down to 1828. Its object from the beginning was the maintenance of public order and good conduct, which were impaired by the misuse of public-houses; and all the successive enactments were directed to that end. They were attempts to suppress or moderate the evils arising from the traffic by regulating it. The excise licensing system has nothing to do with public order or the conduct of the traffic; its object is simply to obtain revenue, and for a long time the two systems were quite independent. But time and change gradually brought them into contact and eventually they came to form two aspects of one unified system. Licensing for revenue was first introduced in 1660 at the same time as duties on the manufacture of beer and spirits: but it was of an irregular character and was only applied to wine, which was not then under the jurisdiction of the justices (as above). In 1710 a special licence was imposed on the retailers of beer and ale and collected by means of a stamp on the justices' licence. In 1728 an annual excise licence of £20 was imposed on retailers of spirits, and in 1736 this was raised to £50 (see above). The object of these particular imposts, however, was rather to check the sale, as previously explained, than to secure revenue. In 1756 the previous tax on the retail sale of wine for consumption on the premises was changed to an annual excise licence, which was in the next year extended to "made wines" and "sweets" (British wines). Similar licences, in place of the previous stamps, were temporarily required for beer and ale between 1725 and 1742 and permanently imposed in 1868. Thus the system of annual excise licences became gradually applied to all kinds of liquor. In 1825 the laws relating to them were consolidated and brought into direct relation with the other licensing laws. It was enacted that excise licences for the retail of liquor should only be granted to persons holding a justices' licence or—to use the more correct term—certificate. The actual permission to sell was obtained on payment of the proper dues from the excise authorities, but they had no power to withhold it from persons authorized by the justices. And that was still the system in 1910.

Licensing since 1828.—There was no change in the form of the British licensing system between the consolidation of the law in 1825-1838 and the time (1910) at which we write; but there were a great many changes in administrative detail and some changes in principle. Only the most important can be mentioned. In 1830 a bold experiment was tried in exempting the sale of beer from the requirement of a justice's licence. Any householder rated to the parish was entitled, under a bond with sureties, to take out an excise licence for the sale of beer for consumption on or off the premises. This measure, which applied to England and was commonly known as the Duke of Wellington's Act, had two objects; one was to encourage the consumption of beer in the hope of weaning the people from spirits; the other was to counteract the practice of "tied" public-houses to breweries by creating free ones. With regard to the first, it was believed that spirit-drinking was increasing again at the time and was doing a great deal of harm. The reason appears to have been a great rise in the returns of consumption, which followed a lowering of the duty on spirits from 11s. 4d. to 7s. a gallon in 1825. The latter step was taken because of the prevalence of illicit distillation. In 1823 the duty had been lowered for the same reason in Scotland from 6s. 2d. and in Ireland from 5s. 7d. to a uniform rate of 2s. 4d. a gallon, with so much success in turning the trade from illegal to legal channels that a similar change was thought advisable in England, as stated. The legal or apparent consumption rose at once from 7 to nearly 13 million gallons; but it is doubtful if there was much or any real increase. According to an official statement, more than half the spirits consumed in 1825 were illicit. The facts are of much interest in showing what had already been shown in the 18th century, that the liquor trade will not bear unlimited taxation; the traffic is driven underground. It is highly probable that this accounts for part of the great fall in consumption which followed the raising of the spirit duty from 11s. 4d. to 14s. 9d. under Mr Lloyd George's Budget in 1909. With regard to "tied" houses, this is the original form of public-house. When beer was first brewed for sale a "tap" for retail purposes was attached to the brewery, and public-houses may still be found bearing the name "The Brewery Tap." At the beginning of the 19th century complaints were made of the increasing number of houses owned or controlled by breweries and of the dependence of the licence-holders, and in 1817 a Select Committee inquired into the subject. The Beerhouse Act does not appear to have checked the practice or to have diminished the consumption of spirits; but it led to a great increase in the number of beer-houses. It was modified in 1834 and 1840, but not repealed until 1869, when beer-houses were again brought under the justices.

Most of the other very numerous changes in the law were connected with conditions imposed on licence-holders. The hours of closing are the most important of these. Apart from the ancient regulations of closing during divine service on Sunday, there were no restrictions in 1828; but after that at least a dozen successive acts dealt with the point. The first important measure was applied in London under a Police Act in 1839; it ordered licensed houses to be closed from midnight on Saturday to mid-day on Sunday, and produced a wonderful effect on public order. In 1853 a very important act (Forbes Mackenzie)
was passed for Scotland, by which sale on Sunday was wholly forbidden, except to travellers and lodgers, and was restricted on week days to the hours between 8 A.M. and 11 P.M. This act also introduced a distinction between hotels, public-houses and grocers licensed to sell liquor, and forbade the sale to children under 14 years, except as messengers, and to intoxicated persons. In England, after a series of enactments in the direction of progressive restriction, uniform regulations as to the hours of opening and closing for licensed premises were applied in 1874, and are still in force (see below). In 1878 complete Sunday closing, as in Scotland, was applied in Ireland, with the exception of the five largest towns, Dublin, Belfast, Cork, Limerick and Waterford; and in 1881 the same provision was extended to Wales.

Other changes worthy of note are the following. In 1860 the free sale of wine for consumption off the premises was introduced by the Wine and Refreshment Houses Act, which authorized any shopkeeper to take out an excise licence for this purpose; the licences so created were subsequently known as grocers' licences. By the same act refreshment houses were placed under certain restrictions, but were permitted to sell wine for consumption on the premises under an excise licence. In 1861 spirit dealers were similarly authorized to sell spirits by the bottle. The effect of these measures was to exempt a good deal of the wine and spirit trade from the control of the justices, and the idea was to wean people from public-house drinking by encouraging them to take what they wanted at home and in eating-houses.

In 1869 this policy of directing the habits of the people into channels thought to be preferable, which had been inaugurated in 1830, was abandoned for one of greater stringency all round, which has since been maintained. All the beer and wine retail licences were brought under the discretion of the justices, but they might only refuse “off” licences and the renewal of previously existing beer-house “on” licences upon specified grounds, namely (1) unsatisfactory character, (2) disorder, (3) previous misconduct, (4) insufficient qualification of applicant or premises. In 1872 an important extension of the policy of restriction; new licences had to be confirmed, and the right of appeal in case of refusal was taken away; penalties for offences were increased and extended, particularly for public drunkenness, and for permitting drunkenness; the sale of spirits to persons under 16 was prohibited. In 1876 many of these provisions were extended to Scotland. In 1886 the sale of liquor for consumption on the premises was forbidden to persons under 13 years. In 1901 the sale for “off” consumption was prohibited to persons under 14, except in sealed vessels; this is known as the Child Messenger Act. These measures for the protection of children were extended in 1908 by an act which came into operation in April 1909, excluding children under 14 from the public-house bars altogether. The progressive protection of children by the law well illustrates the influence of changing public opinion. The successive measures enumerated were not due to increasing contamination of children caused by frequenting the public-house, but to recognition of the harm they came to from excessive drinking, and to the practice of sending children to the public-house, and of serving them with drink, is an old one in England. A great deal of evidence on the subject was given before a Select Committee of the House of Commons in 1834; but it is only in recent years, when the general concern for children has undergone a remarkable development in all directions, that attempts have been made to stop it. In 1902 clubs, which had been increasing, and habitual drunkards, were brought under the law.

In 1904 a new principle was introduced into the licensing system in England, and this, too, was due to change in public opinion. Between 1850 and 1860, under the influence of the legislation described above, a continuous increase in the number of public-houses took place in England; but after 1869 they began to diminish through stricter control, and this process has gone on continuously ever since. Reduction of numbers became a prime object with many licensing benches; they were reluctant to grant new licences, and made a point of extinguishing old ones year by year. At first this was easily effected under the new and stringent provisions of the legislation of 1869-1872, but it gradually became more difficult as the worst houses disappeared and the remaining ones were better conducted, and gave less and less excuse for interference. But the desire for reduction still gained ground, and a new principle was adopted. Houses against which no ill-conduct was alleged were said to be “superfluous,” and on that ground licences were taken away. But this, again, offended the general sense of justice; it was felt that to take away a man’s living or a valuable property for no fault of his own was to inflict a great hardship. To meet the difficulty the principle of compensation was introduced by the act of 1904. It provides that compensation shall be paid to a licence-holder (also to the owner of the premises) whose licence is withdrawn on grounds other than misconduct of the house or unsuitability of premises or of character. The compensation is paid out of a fund raised by an annual charge on the remaining licensed houses. This act has been followed by a large reduction of licences.

State of the Law in 1910.—In consequence of the long history and evolution of legislation in the United Kingdom and of the innumerable minor changes introduced, only a few of which have been mentioned above, the law has become excessively complicated. The differences between the English, Scottish and Irish codes, the distinction between the several kinds of liquor, between consumption on and off the premises, between new licences and the renewal of old ones, between licences licensed before 1869 and those licensed since, between excise and justices' licences—all these and many other points make the subject exceedingly intricate; and it is further complicated by the uncertainty of the courts and a vast body of case-made law. Only a summary of the chief provisions can be given here.

1. The open sale of intoxicating liquor (spirits, wine, beer, cider) by retail is confined to persons holding an excise licence, with a few unimportant exceptions, including medicine.

2. A condition precedent to obtaining such a licence is permission granted by the justices who are the licensing authority and called a justices' licence or certificate. Theatres, passenger boats, and canteens are exempted from this condition; also certain dealers in spirits and wine.

3. Justices' licences are granted at special annual meetings of the local justices, called Brewster Sessions. Justices having a pecuniary interest in the liquor trade of the district, except as railway shareholders, are disqualified from acting; “bns” due to other interests may also be a disqualification.

4. Justices' licences are only granted for one year and must be renewed annually, with the exception of a particular class, created by the act of 1904 and valid for a term of years. Distinctions are made between granting a new licence and renewing an old one. The proceedings are stricter and more summary in the case of a new licence; notice of application must be given to the local authorities; the premises must be of a certain annual value; a plan of the premises must be deposited beforehand in the case of an “on” licence; the justices may impose conditions and have full discretion to refuse without any right of appeal; the licence, if granted, must be confirmed by a higher authority. In the case of old licences on the other hand, no notice is required; they are renewed to the former holders on application, as a matter of right; unless there is opposition or objection, which may come from the police or from outside parties or from the justices themselves. If there is objection the renewal may be refused, but only on specified grounds—namely misconduct, unfitness of premises or character, disqualification; otherwise compensation is payable on the plan explained above. There is a right of appeal to a higher court against refusal. In all cases, whether the justices have full discretion or not, they must exercise their discretion in a judicial manner and not arbitrarily.

5. Licences may be transferred from one person to another in case of death, sickness, bankruptcy, change of tenancy, wilful omission to apply for renewal, forfeiture or disqualification. Licences may also be transferred from one house to another in certain circumstances.

6. A licence may be forfeited through the conviction of the holder of certain specified serious offences.
7. Persons may similarly be disqualified from holding a licence.

8. Liquor may only be sold on the premises specified in the licence and during the following hours:—week-days; London, 5 A.M. to 12.30 P.M. (Saturday, midnight); large towns 6 A.M. to 11 p.m.; other places 6 a.m. to 10 p.m.; Sundays, London, 1 P.M. to 3 P.M., 6 P.M. to 11 P.M.; other places 12.30 P.M. (or 1 P.M.) to 2.30 P.M. (or 3 P.M.), 6 P.M. to 10 P.M.; Christmas Day and Good Friday are counted as Sunday. In Scotland, Wales and Ireland (except the five chief towns) no sale is permitted on Sunday. Licence holders may sell during prohibited hours to lodgers staying in the house and to bona-fide travellers, who must not be less than 3 m. from the place they slept in on the previous night. Extension of hours of sale may be granted for special occasions and for special localities (e.g. early markets).

9. The following proceedings are prohibited in licensed premises: permitting children under 14 to be in a bar, selling any liquor to children under 14 for consumption on the premises, selling liquor to children under 14 as messengers in corked and sealed vessels, selling spirits for consumption on the premises to persons under 16; selling to drunken persons and to habitual drunks; permitting drunkenness, permitting disorders, harbouring prostitutes, harbouring constables, supplying liquor to constables on duty, bribing constables, permitting betting (persistent) or gaming, permitting premises to be used as a brothel. harbouring thieves, permitting seditious meetings; permitting the payment of wages on premises; permitting premises to be used for election committee rooms. In and within 20 m. of London music and dancing are prohibited on licensed premises except under special licences.

10. The police have the right of entry to licensed premises at any time for the purpose of preventing or detecting offences.

11. The injurious adulteration of any liquor is prohibited; also the dilution of beer; but dilution of spirits is not unlawful if the customer's attention is drawn to the fact.

12. All clubs in which intoxicating liquor is sold must be registered. If the liquor is the collective property of the members no licence is required for retail sale, but no liquor can be sold for consumption off the premises. Clubs run for profit, known as proprietary clubs, are on the same legal footing as public-houses.

13. Penalties incurred by licence-holders for offences under the foregoing provisions. For selling any other kind of liquor than that authorized—first offence, fine not exceeding £50 or one month's imprisonment; second offence, fine not exceeding £100 or 3 months' imprisonment with forfeiture of licence and, if ordered, confiscation of liquor and disqualification for five years; third offence, fine not exceeding £100 or six months' imprisonment with forfeiture of licence and, if ordered, confiscation of liquor and unlimited disqualification. Under the Excise Acts the penalty for selling without a licence is—first offence, a fine of £100; upon conviction of liquor, forfeiture of licence and perpetual disqualification; for wine, a fine of £20; for beer or cider "on" consumption £20, "off" consumption £10. For sale to children; first offence, fine up to £2, second offence, fine up to £5. Permitting premises to be used as a brothel, fine of £20, forfeiture of licence and perpetual disqualification. Other offences, fine up to £50 for first conviction, up to £20 for second.

14. The following are offences on the part of the public. Being found drunk on any highway or other public place or on licensed premises; penalty, fine up to 10s. for first conviction, up to 20s. for second, and up to 40s. for third. Riotous or disorderly conduct while drunk; fine up to 40s. Falsely pretending to be a traveller or lodger; fine up to £5. Causing children to be in a bar or sending them for liquor contrary to the law; fine up to £2 for first and up to £5 for second offence. Attempt to obtain liquor by a person notified to the police as an habitual drunkard; fine up to 20s. for first offence, up to 40s. for subsequent ones. Giving drunk persons liquor or helping them to get it on licensed premises; fine up to 40s. or imprisonment for a month. Causing children under 11 to sing or otherwise perform on licensed premises, and causing boys under 14 or girls under 16 to do so between 9 P.M. and 6 A.M.; fine up to £25 or three months' imprisonment.

The foregoing statement of the law does not in all respects apply to Scotland and Ireland, where the administration differs somewhat from that of England. In Scotland the provost and bailies are the licensing authority in royal and parliamentary burghs, and elsewhere the justices. They hold two sessions annually for granting licences and have considerably more power in some respects than in England. The hours of opening are from 8 A.M. to 11 P.M. (week days only), but there is a discretionary power to close at 10 P.M. In Ireland the licensing authority is divided between quarter sessions and petty sessions. Public-house licences are granted and transferred at quarter sessions; renewals and other licences are dealt with at petty sessions. In Dublin, Belfast, Cork, Londonderry and Galway the licensing jurisdiction of quarter sessions is exercised by the recorder, elsewhere by the justices assembled and presided over by the county court judge. The licensing jurisdiction of petty sessions is exercised by two or more justices, but in Dublin by one divisional justice.

Excise Licences and Taxation.—The excise licences may be divided into four classes, (1) manufacturers', (2) wholesale dealers', (3) retail dealers' for "on" consumption, (4) retail dealers' for "off" consumption. Only the two last classes come under the jurisdiction of the justices, as explained above. The total number of different excise licences is between 30 and 40, but

several of them are subvarieties and unimportant or are peculiar to Scotland or Ireland. The duties charged on them were greatly changed and increased by the Finance Act of 1909–10, and it seems desirable to state the changes thus introduced. The table on the previous page gives the principal kinds of licence with the old and the new duties.

There are in addition "occasional" licences valid for one or more days, which come under the jurisdiction of the justices; the duty is 2s. 6d. a day for the full licence (raised to 10s.) and 1s. for beer or wine only (raised to 5s.).

The total amount raised by the excise licences in the United Kingdom for the financial year ending 31st March 1909 was £2,290,028. Of this amount £1,712,160, or nearly four-fifths, was derived from the full or publicans' licence, £26,053 from the wholesale spirit licence and £88,167 from the beer-house licence; the rest are comparatively unimportant. But the licences only represent a small part of the revenue derived from liquor. The great bulk of it is collected by means of duties on manufacture and importation. The total amount for the year ending March 1909 was £17,428,189, or nearly 39% of the total taxation revenue of the country. The excise duties on the manufacture of spirits yielded £17,456,666 and those on beer £12,601,333; customs duties on importation yielded £5,046,949. The excise duty on spirits was at the rate of 11s. 8d. a gallon, raised at the end of April 1909 to 14s. 9d.; the corresponding duty on beer is 7s. 9d. a barrel (36 gallons). The relative taxation of the liquor trade in the United States, which has become important as a political argument, is discussed below.

Effects of Legislation.—The only effects which can be stated with precision and ascribed with certainty to legislation are the increase or diminution of the number of licences or licensed premises; secondary effects, such as increase or diminution of consumption and of drunkenness, are affected by so many causes that only by a very careful, well-informed and dispassionate examination of the facts can positive conclusions be drawn with regard to the influence of legislation (see Temperance). There is no more prolific ground for fallacious statements and arguments, whether unconscious or deliberate. The course of legislation traced above, however, does permit the broad conclusion that great laxity and the multiplication of facilities tend to increase drinking and disorder in a country like the United Kingdom, and that extreme severity produces the same or worse effects by driving the trade into illicit channels, which escape control, and thus really increasing facilities while apparently diminishing them. The most successful course has always been a mean between these extremes in the form of restraint judiciously applied and adjusted to circumstances. The most salient feature of the situation as influenced by the law in recent years is the progressive reduction in the number of licensed houses since 1869. Previously they had been increasing in England.

The number of public-houses, including beer-houses for "on" consumption, in 1831 was 82,466; in 1869 it had risen to 118,602; in 1909 it had fallen again to 94,794. But if the proportion of public-houses to population has been a continuous fall since 1831, as the following table shows—

<table>
<thead>
<tr>

</tbody>
</table>

The change may be put in another way. In 1831 there was one public-house to 168 persons; in 1909 the proportion was 1 to 375. The proportional reduction goes back to the 18th century. In 1732 there was in London one public-house to every 50 persons (see above).

In Scotland the number of public-houses has been diminishing since 1829, when there were 17,713; in 1909 there were only 7,965, while the population had more than doubled. The number in proportion to population has therefore fallen far more rapidly than in England, thus 1831, 1 to 134 persons; 1909, 1 to 60 persons. In Ireland the story is different. There has been a fall in the number of public-houses since 1820, when there were 20,548; but it has not been large or continuous and the population has been steadily diminishing during the time, so that the proportion to population has actually increased, thus 1831, 1 to 305 persons; 1909, 1 to 240 persons. As a whole, however, the United Kingdom shows a large and progressive diminution of public-houses to population; nor is this counterbalanced by an increase of "off" licences. If we take the whole number of licences we get the following movement in recent years—

| No. of Retail Licences ("on" and "off") per 10,000 of Population. |
|---------------------|---------------------|---------------------|
|                     | 1893                | 1903                | 1909                |
| England and Wales   | 46                  | 42                  | 37                  |
| Scotland            | 37                  | 33                  | 30                  |
| Ireland             | 41                  | 46                  | 45                  |
| United Kingdom      | 45                  | 42                  | 37                  |

The diminution in the number of public-houses in England was markedly accelerated by the act of 1904, which introduced the principle of compensation. The average annual rate of reduction in the ten years 1894–1904 before the act was 559; in the four years 1904–1908 after the act it rose to 1,388. The average annual number of licences suppressed with compensation was 1,006,946, contributed by the trade as explained above.

The reduction of public-houses has been accompanied in recent years by a constant increase in the number of clubs. By the act of 1902, which imposed registration, they were brought under some control and the number of legal clubs was accurately ascertained. Previously the number was only estimated from certain data with approximate accuracy. The following table gives the official figures—

<table>
<thead>
<tr>
<th>Clubs: England and Wales.</th>

<tbody>
<tr>
<td>Number of Licences per 10,000</td>
</tr>
<tr>
<td>Proportion</td>
</tr>
</tbody>
</table>

Clubs represent alternative channels to the licensed trade and they are under much less stringent control; they have no prohibited hours and the police have not the same right of entry. In so far, therefore, as clubs replace public-houses the reduction of the latter does not mean diminished facilities for drinking, but the contrary. In the years 1903–1908 the average number of clubs proceeded against for offences was 74 and the average number struck off the register was 52. The increase of clubs and the large proportion struck off the register suggest the need of caution in dealing with the licensed trade; over-stringent measures defeat their own end.

Persistent attempts have for many years been made to effect radical changes in the British system of licensing by the introduction of some of the methods adopted in other countries, and particularly those in the United States. But it is difficult to engrave new and alien methods, involving violent change, upon an ancient system consolidated by successive statutory enactments and confirmed by time and usage. The course of the law and administration since 1869 has made it particularly difficult. The stringent conditions imposed on licence-holders have given those who fulfil them a claim to consideration, and the reduction of licences, by limiting the market, has enhanced their value. An expectation of renewal, in the absence of misconduct, has grown up by usage and been confirmed by the law, which recognizes the distinction between granting a new licence and renewing an old one, by the treasury which levies death duties on the assumption that a licence is an enduring property, by local authorities which assess upon the same assumption, and by the High Courts of Justice, whose decisions have repeatedly turned on this point. The consequence of all this is that very large sums
have been invested in licensed property, which has become part of the settled order of society; and to destroy it by some sudden innovation would cause a great shock. The position is entirely different in other countries where no such control has ever been exercised. It is possible to impose a new system where previously there was none, but not to replace suddenly an old and settled one for something entirely different. Only the most convincing proof of the need and the advantages of the change would justify it; and such proof has not been forthcoming. The British system has the great merit of combining adaptability to different circumstances and to changing customs with continuity and steadiness of administration. The advantages of abandoning it for some other are more than doubtful, the difficulties are real and serious. Over a very long period it has been repeatedly readjusted in conformity with the movement of public opinion and of national habits; while under it the executive have gradually got the traffic well in hand, and a great and progressive improvement in order and conduct has taken place. The process is gradual but sure, and the record will compare favourably with that of any other comparable country. Further readjustment will follow and is desirable. The great defect of the law is its extreme complexity; it needs recasting and simplification.

There are too many kinds of licence, and the classification does not correspond with the actual conditions of the traffic. Some licences are obsolete and superfluous; others make no distinction between branches of the trade which fulfil entirely different functions and require different treatment. The full or publican's licence, which is incomparably the most important, places on the same footing hotels, restaurants, village inns and mere drinking bars, and the lack of distinction is a great stumbling-block. In the attempt made in 1908 to introduce new legislation it was found necessary to incorporate distinctions between different classes of establishment, although that was not contemplated in the original bill. It will always be found necessary whenever the subject is seriously approached, because the law has to deal with things as they actually are. It does not fall within the scope of this article to discuss the numerous controversial questions which arise in connexion with various legislative proposals for dealing with the liquor traffic; but an account of the methods which it has been proposed to adopt from other countries will be found below.

The United States

The liquor legislation of the United States presents a great contrast to that of the United Kingdom, but it is not less interesting in an entirely different way. In place of a single homogeneous system gradually evolved in the course of centuries it embraces a whole series of different ones based on the most diverse principles and subject to sudden changes and frequent experiments. It is not sufficiently understood in Europe that the legislatures of the several states are sovereign in regard to internal affairs and make what laws they please subject to the proviso that they cannot over-ride the Federal law. There is therefore no uniformity in regard to such matters as liquor legislation, and it is a mistake to speak of any particular system as representing the whole country. The United States government only interferes with the traffic to tax it for revenue, and to regulate the sale of liquor to Indians, to soldiers, etc. The liquor traffic is subject—whether in the form of manufacture, wholesale or retail trade—to a uniform tax of 25 dollars (£5) per annum imposed on every one engaged in it. Congress, under the constitution, controls interstate commerce, and the Supreme Court has decided that without its consent no state can prevent a railway or other carrying agency from bringing liquor to any point within its borders from outside. Thus no state can keep out liquor or prevent its consumption, but any state legislature may make what internal regulations it pleases and may prohibit the manufacture and sale altogether within its own borders. It may go further. In 1887 a judgment was delivered by the Supreme Court of the United States that it is within the discretionary power of a state to protect public health, safety and morals even by the destruction of property without compensation, and that the constitution of the United States is not thereby violated. Use has been made of this power in Kansas, and it appears therefore that persons who engage in the liquor trade do so at their own risk. There is in fact no stability at all except in a few states which have incorporated some principle in their constitutions, and even that does not ensure continuity of practice, as means are easily found for evading the law or substituting some other system which amounts to the same thing. As a whole the control of the liquor traffic oscillates violently between attempted suppression and great freedom combined with heavy taxation of licensed houses.

In the great majority of the states some form of licensing exists; it is the prevailing system and was adopted, no doubt from England, at an early period. It is exercised in various ways. The licensing authority may be the municipality or a specially constituted body or the police or a judicial body. The last, which is the method in Pennsylvania, seems to be exceptional. According to Mr Fanshawe there is a general tendency, due to the prevailing corruption, to withdraw from municipal authorities power over the licensing, and to place this function in the hands of of the legislatures, which may be elected or nominated. In New York state the licensing commissioners used to be nominated in cities by the mayors and elected elsewhere; but by the Raines law of 1896 the whole administration was placed under a state commissioner appointed by the governor with the consent of the Senate. A similar plan is in force in some important cities in other states. In Boston the licensing is in the hands of a police board appointed by the governor; in Baltimore and St Louis the authority is vested in commissioners similarly appointed; and in Washington the licensing commissioners are appointed by the president. In Pennsylvania, where the court of quarter sessions is the authority, the vesting of licensing in a judicial body dates back to 1766 and bears the stamp of English influence. It is noteworthy that in Philadelphia and Pittsburg (Allegheny county) the judicial court was for a time given up in favour of commissioners, but the change was a great failure and abandoned in 1888. The powers of the licensing authority vary widely; in some cases the grounds of refusal are conduct and character, and licences are virtually granted to every applicant; in others the discretion to refuse is absolute. In Massachusetts the number of licences allowed bears a fixed ratio to the population, namely 1 to 1000, except in Boston, where it is 1 to 500, but as a rule where licences are given they are given freely. They are valid for a year and granted on conditions. The first and most general condition is the payment of a fee or tax, which varies in amount in different states. Under the high licence system (see below) it generally varies according to the size of the locality and the class of licence where different classes are recognized. In Massachusetts there are six licences; three for consumption on the premises—namely (1) full licence for all liquors, (2) beer, cider, and light wine, (3) beer and cider; two for consumption off the premises—namely (1) spirits, (2) other liquors; the sixth is for druggists. In New York state also there are six classes of licence, though they are not quite the same; but in many states there appears to be only one licence, and no distinction between on and off sale, wholesale or retail. Another condition generally imposed in addition to the tax is a heavy bond with sureties; it varies in amount but is usually not less than 2000 dollars (£400) and may be as high as 6000 dollars (£1200). A condition precedent to the granting of a licence imposed in some states is the deposit of a petition or application some time beforehand, which may have to be backed by a certain number of local residents or taxpayers. In Pennsylvania the required number is 12, and this is the common practice elsewhere; in Missouri a majority of taxpayers is required, and the licence may even be refused, but if the petition is signed by two-thirds of the tax-payers the licensing authority is bound to grant it. This seems to be a sort of genuine local option. Provision is also generally made for hearing objects. Another condition sometimes required (Massachusetts and Iowa) is the consent of owners of adjoining property. In some states no licences are permitted within a

UNITED STATES]

and periodical oscillations of a general character occur in favour of the plan or against it as the result of organized agitation followed by reaction. The wide discrepancies between the practice of different states are shown by some statistics collected in 1907, when the movement was running favourably to the adoption of no licence. In Tennessee the whole state was under prohibition with the exception of 5 municipalities; Arkansas, 56 out of 75 counties; Florida, 35 out of 46 counties; Mississippi, 56 out of 77 counties; North Carolina, 70 out of 97 counties; Vermont, 3 out of 6 cities and 208 out of 241 towns. These appear to be the most prohibitive states, and they are all of a rural character. At the other end of the scale were Pennsylvania with 1 county and a few towns ("town" in America is generally equivalent to "village" in England); Michigan, 1 county and a few towns; California, parts of 8 or 10 counties. New York had 308 out of 933 towns, Ohio, 480 out of 768 towns, Massachusetts, 19 out of 33 cities and 249 out of 321 towns. At the end of 1909 a strong reaction against the prohibition policy set in, notably in Massachusetts.

There is no more uniformity in the mode of procedure than in the results. At least five methods are distinguished. In the most complete and regular form a vote is taken every year in all localities whether there shall be licences or not in the ensuing year and is decided by a bare majority. A second method of applying the general vote is to take it at any time, but not oftener than once in four years, on the demand of one-tenth of the electorate. A third plan is to apply this principle locally and put the question to the vote, when demanded, in any locality. A fourth and entirely different system is to invest the local authority with powers to decide whether there shall be licences or not; and a fifth is to give residents power to prevent licences by means of protest or petition. The first two methods are those most widely in force; but the third plan of taking a local vote by itself is adopted in some important states, including New York, Ohio and Illinois. Opinions differ widely with regard to the success of local veto, but all independent observers agree that it is more successful than state prohibition, and the preference accorded to it by so many states after prolonged experience proves that public opinion broadly endorses that view. Its advantage lies in its adaptability to local circumstances and local opinion. It prevails mainly in rural districts and small towns; in the larger towns it is best tolerated where they are in close proximity to "safety valves" or licensed areas in which liquor can be obtained; the large cities do not adopt it. On the other hand, it has some serious disadvantages. The perpetually renewed struggle between the advocates and opponents of prohibition is a constant cause of social and political strife; and the alternate shutting up and opening of public houses in many places makes continuity of administration impossible, prevents the executive from getting the traffic properly in hand, upsets the habits of the people, demoralizes the trade and stands in the way of steady improvement.

Public Dispensaries.—This entirely different system of controlling the traffic has been in general operation in one state only, South Carolina; but it was also applied to certain areas in the neighbouring states of North Carolina, Georgia and Alabama. The coloured element is very strong in these states, especially in South Carolina, where the coloured far exceeds the white population. The dispensary system was inaugurated there in 1893. It had been preceded by a licensing system with local veto (adopted in 1882), but a strong agitation for state prohibition brought matters to a crisis in 1891. The usual violent political struggle, which is the only constant feature of liquor legislation in the United States, took place, partly on temperance and partly on economic grounds; and a way out was found by adopting an idea from the town of Athens in Georgia, where the liquor trade was run by the municipality through a public dispensary. A law was passed in 1892 embodying this principle but applying it to the whole state. The measure was fiercely contested in the courts and the legislature for years and it underwent numerous amendments, but it survived. Under it the state became the sole purveyor of liquor, buying wholesale from the manufacturers

1 In 1908 local option was adopted in Ohio.
and selling retail through dispensaries under public management and only for consumption off the premises. Many changes were introduced from time to time without abandoning the principle, but in 1907 the system of state control was replaced by one of county administration. Local veto is also in force, and thus the localities have the choice of a dispensary or no sale at all. The regulations are very strict. The dispensaries are few and only open on week-days and during the day-time; they close at sunset. Liquor is only sold in bottles and in not less quantities than half a pint of spirits and a pint of beer, and it must be taken away; bars are abolished. There is a general consensus of testimony to the effect that the system is improving public order especially among the coloured population, who are very susceptible to drink. The law seems to be well carried out in general, but Charleston and Columbia, the only two considerable towns, are honeycombed with illicit drink-shops, as the writer has proved by personal experience. Columbia is the capital and the seat of cotton manufactures, as are all the larger towns, with the exception of Charleston, which is the port and business centre. The population of the state is predominantly rural, and local prohibition obtains in 18 out of 41 counties.

The following comparative compendium extracted from the United States Census of 1900 and the Inland Revenue Returns by Mr W. O. Tatum (New Encyclopedia of Social Reform) and here presented in tabular form, is highly instructive. It shows the population and number of liquor dealers paying the United States tax in prohibition states, one state under what is considered the best licensing system, and South Carolina.

This table may be said to epitomize the results of the United States restrictive liquor laws. It presents examples of three different systems; the proportion of retail liquor sellers to population is—under complete prohibition, 1 to 508 and 1 to 475; under licence and local prohibition, 1 to 530; and under general prohibition, 1 to 2,590. But the remarkable thing is the enormous amount of illicit traffic existing under all three systems. It is incomparably greatest under complete prohibition because the whole of the traffic in these states is illicit. In South Carolina one of the wholesale liquor dealers in that state, where the law is in full force, makes a large part of the state, probably more than half, is under local prohibition, so that the majority of the 5,000 retail dealers must be illicit. These facts, which are typical and not exceptional, reveal the failure of the laws to control the traffic for which the latter varies greatly, even in those states which have adopted the "high licence." This system is intended to fulfill two purposes; to act as an automatic check on the number of licences and to produce a revenue. The licence tax in Massachusetts, where the high licence was adopted in 1874 when the state returned to licensing after a trial of prohibition, the fees are exceptionally high, the minimum for a fully licensed on and off house being $1,500 ($200); in Boston the average tax is $3,400. In New York the average state licence fee on sparsely populated districts to $200 ($240), and in Pennsylvania it is much the same. In New Jersey, on the other hand, it ranges from $20 to $80; in Connecticut from $50 to $100; in Rhode Island from $50 to $200. In Missouri, which has a special system of its own and a sort of sliding scale, great variations occur and in some states the tax exceeds $500. The mean for the large cities is $153. The revenue derived from this source is distributed in many ways, but is generally divided in varying proportions between the state, the county and the municipality; sometimes a proportion goes to the relief of the poor, to road-making or some other public purpose. The amount levied in the great cities is very large. It will be seen from the foregoing that the taxation of licences is much heavier in the United States than in the United Kingdom. The total yield was ascertained by a special inquiry in 1896 and found to be rather less than 12 millions and about the same as the licence revenue in the United Kingdom was just under 2 millions. Allowing for difference of population the American rate of taxation was 3½ times as great as the British. It has been inferred that the liquor trade is much more highly taxed in the United States and that it would bear a much heavier tax than is the United Kingdom, if the same amount was brought forward in support of Mr Lloyd George's budget of 1909. But it only takes account of the tax on licences and leaves out of account the tax on liquor which is the great source of revenue. In the United States licences are much more heavily taxed than in the United Kingdom, so that the total revenue is much lower in the United States, especially on spirits, which are only taxed at the average rate of 5s. 8d. a gallon against 11s. (raised to 14s. at £1 in 1909) in the United Kingdom. Mr Frederic Thompson calculated out the effect of the two sets of rates and showed that if British rates were applied to the United States the average yield in the three years ending 1908 would be raised from 44 millions to 76 millions; and conversely if American rates were applied to the United Kingdom the average yield would be lowered from 36 millions to 23 millions. Taking licences and liquor taxation together he finds that the application of the British standards for both would still raise the total yield in the United States by 3½; and that the taxation of illicit traffic in the United States is the most outstanding feature of the traffic in the United States, and combined with the extreme insecurity of tenure involved in local option it gives licences-holders additional inducements to make as much money as they possibly can. The opportunity, for no compensation is ever paid for sudden dispossession. The notion that the trade will stand an indefinite amount of taxation is a dangerous and oft-proved fallacy.

European Countries.

With the exception of Sweden, Norway and Russia, which have special systems of their own, the continental countries of Europe have as yet paid comparatively little legislative attention to the subject of the liquor traffic, which is recognized by the law but for the most part freely permitted with a minimum of interference. Differences exist, but generally speaking, establishments may be opened under a very simple procedure, which amounts to an elementary form of licensing, and the permission is only withdrawn for some definite and serious offence. Regulations and conditions are for the most part left to the discretion of the local authority and the police and are not burdensome. The reason for such freedom as compared with the elaborate and stringent codes of the United Kingdom and the United States is not less concern for public welfare but the simple fact that the traffic gives less trouble and causes less harm through the abuse of drink; the habits of the people are different and their ideas in regard to temperance have been more or less shaped by the circumstances in which they have found themselves. The usual mode of establishment is the coffee-house, the tavern, the public-house, the beer-garden, and the restaurant, all of which are more or less under license. But the example of the United States is not followed, and the sale of liquor is not distributed among so many dealers, though the present licensing system, which is a compromise between the free trade of the Americans and the prohibitory law of the English, has been found highly unsatisfactory. The sale of liquor is regulated by the local authorities, and in France the right to sell it is an exclusively municipal privilege. The tax on liquor is in some countries very heavy, but in others it is negligible. The revenue obtained from it is used for various public purposes, especially education and the encouragement of agriculture.
France.—The present law governing the licensing of establishments where liquor is sold for consumption on the premises was passed in 1880; it abrogated the previous decree of 1851, by which full discretion was vested in the local authorities, and freed the trade from all omissions, except those relating to premises that, desiring to open a café, cabaret or other place for retailing liquor must give notice to the authorities, with details concerning himself, the establishment and the proprietor, at least 15 days beforehand; he is not to be allowed to open the doors before 10 a.m. nor after 11 p.m., nor is he to commix its premises with sordid or immoral. Transfers of proprietorship or management must be notified within 15 days, and intended transference of location 8 days beforehand. The penalty for infraction is a fine of 16 francs to 100 francs. Legal maxims have been laid down by the courts: the law is not to be invoked to the detriment of the local authority. The local authority has full power to regulate the distance of such establishments from churches, cemeteries, schools and colleges, etc. But persons engaged in the trade, who are in violation of the law, are subject to the fines or fines on the premises mentioned above and of the suppression of public drunkenness, are disabled, as above. The law practically amounts to free trade and the number of houses has increased; in 1900 there was one to every 81 persons. This proportion is only exceeded by Belgium. Under the Local Government Act of 1884 municipal authorities are empowered, for the maintenance of public order, to fix hours of closing, regulate dances and similar entertainment. The law also provides that prostitutes and make other regulations. The hours of closing differ considerably but usually they are 11 p.m., midnight or 1 a.m. The trade is lightly taxed; retailers pay from 15 to 50 francs a year for each licence he holds, whereas the same in most municipalities, distilleries 25 francs. The excise revenue from liquor amounted to £20,000,000 in 1900.

Germany.—The German law and practice are broadly similar to those of France. German law has not been under the influence of the English law, and the German law did not require the granting of a licence for retailing spirits on or off the premises. The plan of the German empire, however, can only be described as a more or less complete system of keeping records of the capital and the sale of spirits. The general law of the empire; but the state governments are empowered to make the granting of a licence for retailing spirits dependent on proof that it is locally required, and also to impose the fee required by the latter. The fees payable for the sale of spirits are limited in places with less than 15,000 inhabitants and in larger which obtain a local statute to that effect. Before a licence is granted the opinion of the police and other executive officers is to be taken. The trade is not regulated by the municipal authorities, but by the district council in rural areas. The provisions with regard to the dependence of a licence on local requirements have not been adopted by Prussia and other states, but apparently little or no use is made of them. Permits are very freely granted, and the number of licensed houses, though not so great as in France, is very high in proportion to population. Three classes of establishment are recognized, (1) Gast-wirtschaft, (2) Schank-wirtschaft, (3) Kleinhandel. The Gast-wirtschaft is an open house for profit, and includes "pensions" of a public character; the imperial law provides that a licence may be granted to any kind of business, but it is not required under the local law, and need not include the retailing of liquor. Schank- wirtschafts are licensed to sell only spirits and beer, and are subject to a tax of 6d. per gallon, and no coffee or mineral waters; it corresponds to café in France and refreshment houses in England; but the mere serving of food does not come under the law with which we are here concerned. Kleinhandel is a retail sale either for or on off-consumption, and the licence, for which a licence is required in this connexion is described as brantwein or spiritus, and is defined as distilled alcoholic liquor, whether by still or in combination. A licence for Schank- wirtschaft is sometimes given to vendors engaged in the wine trade, but a licence is not required for the retail sale of wine which is the seller's own produce. Licences may be withdrawn for offences against the law. Licensed houses are subject to a number of restrictions, in respect of the time of keeping open, and the number of new licences which may be granted in a certain period. The law is generally in force; it is usually 10 p.m., but is commonly extended to 11 p.m. or midnight in the larger towns and still later in the case of particular establishments. Some cafes in Berlin do not close till 3 a.m. and some never shut up. They may be closed for a period of 24 hours after being ordered to leave by the landlord are liable to punishment. Serving drunkards and persons of school age is forbidden. Drunkards, in addition to fines or imprisonment for disorderly conduct, are liable to a fine of £5 and placed under guardianship. For music and dancing special permits are required. With regard to taxation, in Prussia all business establishments beyond a certain value pay an annual tax and there is a tax on the sale of spirits. These taxes, producing less than £5 a year or of less than £150 capital value are free; the rest are arranged in four classes on a rising scale. In the three lower classes the tax ranges from a minimum of 4s. to a maximum of £250; in the highest class, which represents businesses producing £2,500 and upwards (or a capital value of £50,000 and upwards) the tax is 1% of the profits. There is also a stamp duty on the licence ranging from 1s. 6d. to 5s. The latter goes to the local revenue, the business tax to the government. Beer and spirits are also subject to an excise tax, from which the imperial revenue derived £7,200,000 in 1901; but the total taxation of the liquor trade could only be calculated from the returns of all the federated states.

The laws of France and Germany are fairly representative of the European states, with some minor variations. In Holland the number of licensed spirit retailers is limited in proportion to population. The law, which was passed in 1881, allows both national and local, ranges from 10 to 25% of the annual value. In Austria-Hungary and Rumania the licence duty is paid according to the population of the place, as was used as a tax on the sale of spirits in Prussia. In 1874 a purely local law was applied in Galicia in order to check the excesses of spirit-drinking. The Poles, it may be observed, are spirit-drinkers, and the exceptional treatment of this part of the empire is partly explained by the fact that spirit-drinking is arising from that habit, which forces special attempts to restrain it. The law, just mentioned, in Holland is another instance; and the particular cases of Russia and Scandinavia, described below, enforce the same principle, but they are less severe. There are no other taxes on wine and beer there is comparatively little trouble. In Switzerland the manufacture and wholesale sale of spirits has been a federal monopoly since 1887, but the retailing is a licensed trade, as elsewhere, and is less restricted than formerly. Before federation in 1854 the cantons used to direct local authorities to restrict the number of licences in proportion to population; but under the new constitution the general principle of free trade was laid down, and the Federal Council is forbidden to make rules which would restrict the importation of wine or beer. France was in the same situation as Austria, when it was able to refuse a licence on the ground that it was not needed.

Russia.—In 1895 Russia entered upon an experiment in regard to the spirit traffic and began to convert the previously existing license into one that was more comprehensive in form and more serviceable and was gradually extended to the whole country. Under this system, which to some extent resembles that of South Carolina but is much less rigid, the distilleries remain in private hands, and the government acquires the right to buy the spirit at half the market price in sealed bottles for consumption off the premises, and to commercial establishments which sell on commission for the government. Spirit bars are permitted, and the purchase of spirit is made by the glass; in ordinary eating-houses and at railway refreshment rooms they are sold in sealed government bottles but may be consumed on the premises. The private object was to check the spread of spirit-drinking which was very prevalent among the mass of the people. The effect has been a very large reduction in the number of liquor shops, which has extended also to the licensed beer-houses though they are not directly affected as such. In addition to the purchase for government the state longer sells spirits it did not pay them to take out a licence for beer.

Sweden and Norway.—In these countries the celebrated "Gothenburg" or company system is in force, with the licensing and control of the manufacture and sale of spirituous liquors. It is of an entirely different character, and applies only to spirits, and for the same reason; spirits are or were the common drink of the people and excessive facilities in the early part of the 19th century produced the usual result. The story is one of the most interesting of its kind. In 1774 to 1788 distilling in Sweden was a crown monopoly, but popular opposition and illicit trade compelled the abandonment of this plan in favour of general permission granted to farmers, inn-keepers and the like to keep shops and the right to sell spirits, the right to distil belonged to every owner and cultivator of land on payment of a trifling licence duty, and it was further extended to occupiers. In 1829 the number of stills paying licence duty was 173,124 or 1 to every 16 persons; the practice was in fact universal and the whole population was debauched with spirits. The physical and moral results were the same as those recorded in England a hundred years before. The supply was somewhat restricted by royal orders in 1797, and the commercial monopoly was restored in 1816, but was gradually relaxed until 1855, when a law was passed which practically abolished domestic distilling by fixing a minimum daily output of 200 gallons, and which turned the business into a manufacture and specifically reduced the quantities sold. At the same time the retail sale was subjected to drastic regulations. A licensing system was introduced which gave the local authority power to revoke or suspend a licence on the ground that it was not applied by the towns until 1865, when Gothenburg was adopted it.

In Norway the course of events was very similar. There, too, distilling and spirit-drinking were practically universal in the early part of the century under the laws of 1816, but were checked by legislation a few years sooner than in Sweden. In 1845 a special licensing system was introduced, giving the local authority power to fix the number of licences, and in 1848 the small and domestic
The Gothenburg system was adopted in Sweden in 1871 and then with some modification. The essence of this method of conducting the retail traffic is that the element of private gain is eliminated. A monopoly is granted to a company consisting of two or more persons. It is established out of the capital, and they manage the sale both for "on" and "off" consumption in the public interest. The profits, after payment of 5% on the capital, originally went in Sweden mainly to the municipality in relief of the direct taxation of the town. The intention to obtain a monopoly to eliminate delict was considered preferable because it offers less temptation to make the profits as high as possible. Fault has, however, been found with both methods, and payment of profits to the state is now preferred. In 1913 the net profits of the companies exceeded half a million sterling in Sweden and reached £1,175,000.

The company system had in 1910 had more than half a century's trial through some vicissitudes to the best advantage, a test much criticized, which was balanced by at least as much utility. It had held its own in Sweden, where 101 towns had adopted it in 1906. In Norway at the same date it was in force in 32 towns while 20 had adopted local veto, which was extended from the country districts, where it had previously been optional, to the towns by the law of 1894.

As we have already said, it only applies to spirits. In both countries the on-sale duty is paid on the sale of spirits, the local option being in the ordinary way under a licensing system; the sale of beer in bottles for consumption off the premises is practically free. The beer trade is regulated by some as a "safety valve" and by others as an "essential right." The consumption is usually 6% in Sweden; in Norway it increased up to 1900 and has since declined. But other more deleterious substitutes for spirits have come into use in the shape of concentrated wines and methylated spirits. The Norwegian liquor commission has "decreed" that the local option has greatly reduced the number of spirit bars, improved their character and conduct, added eating-rooms, where good and cheap meals are served, stopped drinking on credit and by persons under 18 years of age, shortened the hours of sale, raised the selling strength of spirits. But the restrictions placed on the sale for consumption on the premises has stimulated the retail bottle trade and home drinking.

**British Dominions.**

**Canada.**—Liquor legislation in Canada has been much influenced by the British example. In the United States, licensing, modified by local veto, prevails throughout the Dominion except in the Indian settlements; but the several provinces have their own laws, which vary in stringency. As a whole the licensing system rather favors the American than the British type. The licensing authority is either a board of commissioners or the municipality, and there has been the same tendency as in the United States to substitute the latter for the former. In British Columbia no local board of directors has been, however, replaced by original municipalities. The power of sale is generally limited to the owners and occupiers of the adjoining property, but their consent is not necessary for renewal. In other provinces the municipal licensing authority has power to limit as well as to regulate the licensed trade. In all of them the hours of sale vary. The closing hour in the large towns is 11 p.m. The power of locally prohibiting licensed houses by vote was introduced by the Canadian Temperance Act, a federal law passed in 1873 and commonly known as the Scott Act. Extensive use has been made of it, especially in the most infertile provinces, where the temperance sentiment is very strong, but in recent years it has rather lost ground. In 1908 it was in force in 22 counties or cities, of which ten were in Nova Scotia, ten in New Brunswick and two in Alberta, in that province which was the last to prohibit the licence.

**LIRA—Liroconite.**

The total revenue derived by the Dominion government in 1908 from taxation of the liquor trade, including duties and licence fees, was £1,880,000.

**Australia.**—The licensing laws of Australia are less repressive and, a wide territorial system. Some parts are under New South Wales, with the same together with a provision for the introduction of retail licences; in other the commercial licence is to be abolished and replaced by a system of option both ways, for reducing or increasing the licences; in Tasmania all retail licences are abolished. In Western Australia and Queensland it will be good against new licences. In New South Wales, the maximum number of licences granted is 1906, and the number of renewals may be made after amendments and transfers also, but the decision lies with the licensing authority. There is practically no prohibition in the Commonwealth.

As in any licensing system with local option provisions of its own. The licensing authority is a local committee, and there are seven kinds of licence, of which two are for consumption on the premises. The fees range from £1 for a wine licence to £40 for a full publican's licence in towns, or £1,800 for permits, an additional hour's sale at night; the fees go to the revenue of the local authority. In 1907 the total number of licences granted was 1,279 and the fees paid amounted to £4,863. Of the whole number, 339, or 27%, have been granted for the purpose of the House of Representatives, except that the cities of Auckland, Wellington, Christchurch and Dunedin each form a single district for the licensing poll. It is found that the licensing authority has grappled with the problem of the House of Representatives, and three questions are proposed: (1) continuance of existing licences, (2) reduction, (3) no licences. A voter may vote for two proposals but not more. An absolute majority is required for the adoption of any proposal, and two-thirds of the votes recorded carries (2), whereupon the licensing committee reduces the licences by any number from 5 to 25% of the total. But if three-fifths of all the votes cast are in favour of no licence at all, the panel and the election of members of the House of Representatives are subject to the vote on the three proposals. The following results: of the 68 districts 40 carried no proposal (which is equivalent to continuance of existing licences), 18 carried continuance, 4 reduction, 6 no licence, including 3 which carried continuance and reduction. The aggregate vote in favour of no licence shows a large proportional increase since the first poll in the present system in 1866.

**LIRA,** the Italian term (Lat. *libra*, pound) for a silver coin, the Italian unit of value in the Latin Monetary Union, corresponding to the French, Swiss and Belgian franc (q.v.), and the drachma of Greece, &c. The name is sometimes used of the Turkish pound, *mehdiye.*

**LIRI,** or GAGLIONI (anc. *Liris*), a river of central Italy, which rises at Cappadocia, 7 m. W. of Avezzano, and traverses a beautiful valley between lofty mountains, running S.S.E. as far as Arce. This valley is followed by the railway from Avezzano to Roccasucco. At Isola del Liri there are two fine waterfalls. Below Cepano, the ancient Fregellae, after it has issued from the mountains, the Liri enters a large plain formed by the union of several torrents between Palestrina and Segni, and the Mela from the mountains N.E. of Atina, and runs E. through a broader valley. It then turns S. again through the mountains S.W. of the Via Latina (the line of which is followed by the modern railway to Naples), keeping W. of Rocca Monfina, and falls into the sea just below Minturnae, after a course of 104 m. It is not navigable at any point.

**LIROCONITE**, a rare mineral consisting of hydrous basic copper and aluminium arsenate, with the probable formula
LISBON, the capital of the kingdom of Portugal and of the department of Lisbon; on the right bank of the river Tagus, near its entrance into the Atlantic Ocean, in 38° 42′ 24″ N. and 9° 11′ 10″ W. Pop. (1900) 335,009. Lisbon, the westernmost of European capitals, is built in a succession of terraces up the sides of a range of low hills, backed by the granite mountains of the Serra de Penha. It fronts the Tagus, and the view from the river of its white houses, and its numerous parks and gardens, is comparable in beauty with the approach to Naples or Constantinople by sea. The lower reaches of the estuary form a channel (Entrada do Tejo) about 2 m. wide and 8 m. long, which is partially closed at its mouth by a bar of silt. Owing to the reclamation of the foreshore on the right, and the consequent narrowing of the waterway, the current flows very swiftly down this channel, which is the sole outlet for the immense volume of water accumulated in the Rada de Lisboa—a tidal lake formed by the broadening of the estuary in its upper part to fill a basin 11 m. long with an average breadth of nearly 7 m. The southern or left shore of the channel rises sharply from the water’s edge in a line of almost unbroken though not lofty cliffs; the margin of the lake is flat, marshy and irregular. Lisbon extends for more than 5 m. along the shores of both channel and lake, and more than 0.33 m. along the Tagus. Its suburbs, which generally terminate in a belt of vineyards, parks or gardens, interspersed with villas and farms, stretch in some cases beyond the Estrada Militar, or Estrada da Nova Circumvallação, an inner line of defence 25 m. long, supplementary to the forts and other military works at the mouth of the Tagus, on the heights of Cintra and Alverca, and at Caxias, Sacavém, Monsanto and Ameixoeira. The climate of Lisbon is mild and equable, though somewhat oppressive in summer. Extreme cold is so rare that in twenty years 1856–1876 snow fell only thrice; and in the 15th and 16th centuries Lisbon was justly esteemed as a winter health-resort. The mean annual temperature is 69° F., the mean for winter 59°, the average rainfall 29.45 in. As in 1606, when no rain fell between April and September, long periods of drought are not uncommon, although the proximity of the Atlantic and the frequency of sea-fogs keep the atmosphere almost humid; the mean atmospheric moisture is nearly 71% (100% saturation). There is a good water supply, conveyed to the city by two vast aqueducts. The oldest of these is the Aqueduto das Águas Livres, which was built in the first half of the 18th century and starts from a point near Belas, 15 m. W.N.W. Its conduits, which are partly underground, are conveyed across the Alcântara valley through a magnificent viaduct of thirty-five arches, exceeding 200 ft. in height. At the Lisbon end of the aqueduct is the Mae d’Água (i.e. “Mother of Water”), containing a huge stone hall in the midst of which is the reservoir. The Alviella aqueduct, opened in 1850, brings water from Alviella near Penafiel, 70 m. N.N.E. Numerous fountains are among the means of distribution. Sewage is discharged into the Tagus, and the sanitation of the city is good, except in the older quarters.

Divisions of the City. — The four municipal districts (bairros) into which Lisbon is divided are the Alfama, or old town, in the east; the Cidade Baixa, or lower town, which extends inland from the naval arsenal and custom house; the Bairro Alto, comprising all the high ground west of the Cidade Baixa; and the Alcântara, or westernmost district, named after the small river Alcântara, which flows down into the Tagus. Other names commonly used, though unofficial, are “Lisboa Oriental” as an alternative for Alfama; “Lisboa Occidental” for the slopes which lead from the Cidade Baixa to the Bairro Alto; “Buenos Ayres” (originally so named from the number of its South American residents) for the Bairro Alto S.W. of the Estrela Gardens and E. of the Necessidades Park; “Campo de Ourique” and “Rato” for the suburbs respectively N.W. and N.E. of Buenos Ayres.

The Alfama. — The Alfama, which represents Roman and Moorish Lisbon, is less rich in archaeological interest than its grandeur might suggest, although parts of a Roman temple, baths, &c., have been disinterred. But as the earthquake of 1755 did comparatively little damage to this quarter, many of its narrow, steep and winding alleys retain the medieval aspect which all other parts of the city have lost; and almost rival the slums of Oporto in picturesque squalor. The most conspicuous feature of the Alfama is the rocky hill surmounted by the Castello de São Jorge, a Moorish citadel which has been converted into a fort and barracks. The Sé Patriarchal, a cathedral founded in 1139 by Alphonso I., is said by tradition to have been a Moorish mosque. It was wrecked by an earthquake in 1344 and rebuilt in 1380, but the earthquake of 1755 shattered the dome, the roof and belfry were subsequently burned, and after the work of restoration was completed the choir and façade were the only parts of the 14th-century Gothic church unspoiled. In one of the side chapels is the tomb of St Vincent (d. 304), patron saint of Lisbon; a pair of ravens kept within the cathedral precincts are popularly believed to be the same birds which, according to the legend, miraculously guided the saint’s vessel to the city. The armorial bearings of Lisbon, representing a ship and two ravens, commemorate the legend. Other noteworthy buildings in the Alfama are the 12th-century church of São Vicente de Fora, originally, as its name implies, “outside” the city; the 13th-century chapel of Nossa Senhora do Monte; and the 15th-century church of Nossa Senhora da Graça, which contains a robed wooden image of Christ and the tomb of Alphonso d’Albuquerque (1453–1515) and an Augustinian monastery, used as the archbishop’s palace.

Modern Lisbon. — West of the Alfama the city dates chiefly from the period after the great earthquake. Its lofty houses, arranged in long straight streets, its gardens and open spaces, a few of its public buildings, and almost all its numerous statues and fountains, will bear comparison with those of any European capital. The centre of social and commercial activity is the district which comprises the Praça do Comércio, Rua Augusta, Rocio, and Avenida da Liberdade, streets and squares occupying the valley of a vanished tributary of the Tagus. The Praça do Comércio is a spacious square, one side of which faces the river, while the other three sides are occupied by the arcaded buildings of the custom house, post office and other government property. In the midst is a bronze equestrian statue of Joseph I., with a statue of Vicente de Castro, which was erected in 1775 and gives point to the name of “Black Horse Square.” The Praça do Comércio is connected with the Praça by the British. A triumphal arch on the north side leads to Rua Augusta, originally intended to be the cloth-merchants’ street; for the plan upon which Lisbon was rebuilt after 1755 involved the restriction of each industry to a specified area. This plan succeeded in the neighbouring Rua Aurea and Rua da Prata, still, as their names indicate, famous for goldsmiths’ and silversmiths’ shops. Rua Augusta terminates on the north in the Rocio or Praça do Dom Pedro Quarto, a square paved with mosaic of a curious undulatory pattern and containing two bronze fountains, a lofty pillar surmounted by a statue of Pedro IV., and the royal national theatre (Teatro de Dona Maria Segunda), erected on the site which the Inquisition buildings occupied from 1320 to 1836. The narrow Rua do Principe, leading past the central railway station, a handsome Mauresque building, connects the Rocio with the Avenida da Liberdade, one of the finest avenues in Europe. The central part of the Avenida, a favourite open-air resort of Lisbon society, is used for riding and driving; on each side of it are paved double avenues of trees, with flower-beds, statues, ponds, fountains, &c., and
between these and the broad pavements are two roadways for trains and heavy traffic. Thus the Avenida has the appearance of three parallel streets, separated by avenues of trees instead of houses. Its width exceeds 300 ft. It owes its name to an obelisk 82 ft. high, erected in 1882 at its southern end, to commemorate the liberation of Portugal from Spanish rule (December, 1910). North and north-east of the Avenida are the Avenida Park, the Edward VII. Park (so named in memory of a visit paid to Lisbon by the king of England in 1903), Campo Grande, with its finely wooded walks, and Campo Pequeno, with the bull-ring. Other noteworthy public gardens are the Passeio da Estrela, commanding magnificent views of the city and river, the Largo do Principe Real, planted with bananas and other tropical trees, the Tapada das Necessidades, originally the park of one of the residences of the Portuguese royal family, and the Botanical Gardens, an old technic school, with a fine avenue of palms and collections of tropical and subtropical flora hardly surpassed in Europe. There are large Portuguese cemeteries east and west of Lisbon, a German cemetery, and an English cemetery, known also as Os Cyprestes from the number of its cypresses. This was laid out in 1717 at the cost of the British and Dutch residents and contains the graves of Henry Fielding (1712-1754), the novelist, and Dr Philip Doddridge (1702-1751), the Non-conformist divine.

Lisbon is the seat of an archbishop who since 1716 has borne ex officio the honorary title of patriarch; he presides over the House of Peers and is usually appointed a cardinal. The churches of modern Lisbon are generally built in the Italian style of the 18th century; the interiors are overlaid with heavy ornament. Perhaps the finest is the Estrela church, with its marble dome and twin towers visible for many miles above the city. The late Renaissance church of São Roque contains two beautiful chapels dating from the 18th century, one of which is inlaid with painted tiles, while the other was constructed in Rome of coloured marbles, and consecrated by the pope before being shipped to Lisbon. Its mosaics and lapis lazuli pillars are exceptionally fine. The 14th-century Gothic Igreja do Carmo was shattered by the great earthquake. Only the apse, pillared aisles and outer walls remain standing, and the interior has been converted into an archaeological museum. The church of Nossa Senhora da Conceição has a magnificent Manoeline façade.

The palace of Castilho, in which both lines of Parliament sit, is a 16th-century Benedictine convent, used for its present purpose since 1814. It contains the national archives, better known as the Torre do Tombo collection, because in 1375 the archives were first stored in a tower of that name. The royal palace, or Paço das Necessidades, west of Buenos Ayres, is a vast 18th-century mansion occupying the site of a chapel dedicated to Nossa Senhora das Necessidades (i.e. "Our Lady who helps at need").

The Suburbs of Ajuda and Belém.—In the extreme west of Lisbon, beyond the Alcântara valley, are Belém (i.e. "Bethlehem"), beside the Tagus, and Ajuda, on the heights above. The Paço de Belém, built in 1790 for the counts of Aveiro, became the chief royal palace under John V. (1756-1777). The Torre do Belém, on the foreshore, is a small tower of beautiful design, built in 1520 for the protection of the Tagus navigation. The church, however, is the more important of the two. The sable façade and bell-tower are of the same period as the Torre do Tombo, and the interior contains many royal tombs, including that of Catherine of Braganza (d. 1705), the wife of Charles II, of England. The tower of the Casa dos Camões and Vasco da Gama was intended for William III, Prince of Orange, by João de Castilho (d. 1581), perhaps the greatest of Manoeline architects.

This loses its form to a square blunt corner, surrounded by a two-storied arcade, every available portion of which is covered with carved stonework. Parts of the buildings have been restored, but the cloisters and the beautiful central gateway remain unspoilt. The interior contains many royal tombs, including that of Catherine of Braganza (d. 1705), the wife of Charles II, of England. The church, also referred to above, was consecrated by the archbishop here in 1880. In 1834, when the convent was secularized, its buildings were assigned to the Casa Pia, an orphanage founded by Maria I. Since 1902 they have contained the archaeological collections of the University of Lisbon. The palace of Belém was begun (1821-1826) by John VI, but left unfinished, derives its name from the chapel of N. S. de Ajuda ("Our Lady of Aid"). It contains some fine pictures and historical trophies. In the coach-house there is an unssparred collection of state coaches, the cars upon which figures of saints are borne in procession, sedan chairs, old cabiriobots and other curious vehicles.

The Environs of Lisbon.—The administrative district of Lisbon has an area of 3065 sq. m., with a population of 760,500 in 1900. It comprises the lower parts of the Tagus and Sado and Setúbal, the coast from 5 m. S. of Cape Carvoeiro to within 3 m. of the bluff called the Escarpa do Rojo; and a strip of territory extending inland for a distance of 30 m. This region corresponds with the southern part of Estremadura and the Portuguese counties of Alentejo, Beira, Coimbra, and Estremadura. The coast consists of sandy shores, with the hamlet of Trafañia, inhabited by fishermen. The beautiful strip of coast west of Oeiras and south of Cape Roca is often called the "Portuguese Riviera." Its fine climate, mineral springs and sea-bathing facilities make it a popular resort for visitors from all parts of the world. The modern towns consisting chiefly of villas, hotels and gardens. The village of Cascaes, or to Estoril, Mont' Estoril and São João do Estoril, were formerly the residences of the Portuguese nobility. Other villages of interest are Cascaes, or to Estoril, Mont' Estoril and São João do Estoril, the villages of Cascaes, Bucellas, Luniar and Collares produce excellent wines; at Carcavelos the receiving station for cables, with a large British staff, and a club and grounds where social and athletic meetings are held by the British colony. Albandra, on the right bank of the Tagus, above Lisbon, was the birthplace of Albuquerque; fighting bulls for the Lisbon arena are bred in the adjacent pastures.

Railways, Shipping and Commerce.—Lisbon has five railway stations—the central (Lisboa-Rodo), for the lines to Cintra, northern and central Portugal, and Madrid via Valencia de Alcântara; the Santa Apolonia or Caes dos Saldados, at the eastern extremity of the quays, for the same lines; the Estrela, for lines to the interior of Portugal; the Castilho (i.e. Castelo Branco) and the Saldados, farther west along the lines, for the interior; and the Barreiro, on the left bank of the Tagus, for southern Portugal. In 1902 the railways north and south of the Tagus were connected near Lisbon by a bridge. In the previous year an extensive system of electric tramways replaced the old-fashioned cable cars and mule trains. Electric and hydraulic lifts are used where the streets are too steep for trams. Lisbon is lighted by both electricity and gas; it has an admirable telephone service, and is connected by the Carcavelos cable-station with Cornwall (England), Vigo in Galicia, Gibraltar, the Azores and Madeira.

Ships of the largest size can enter the Tagus, and the Barreiro inlet is navigable at low water by vessels drawing 16 ft. There are extensive quays along the Tagus bank, with hills ideal for athletic events, two graving docks, a slipway, warehouses and lines of railway. The government and private docks are on the left bank. Loading and discharging are principally effected by means of lighters. The imports are wines, oil, fruit, tinned fish, salt, colonial produce, cork, pitwood, leather and wool. The imports include cotton and woolen goods, linen, ale and porter, butter, tea, hardware, tin plates, coal, iron, machinery, chemical manure, &c., from Great Britain; grain and petroleum from the United States; dried codfish from Norway and Newfoundland; silks, perfumery and fancy goods from France; hemp, flax, grain, petroleum and cloth from Russia; linen, machinery, hardware, sugar, &c., from Germany and Holland; iron, steel, timber, pitch and salt fish from the Baltic; cocoa, coffee, wax and rubber from the Portuguese colony of Angola; and the sea-coast of Aldeia do Caborão. The tourist traffic from Great Britain and Germany attained considerable importance, and Lisbon has long been one of the principal ports of debarkation for passengers from Brazil and of embarkation for emigrants to South America. Shipbuilding, including the construction of vessels for the national navy, is a growing industry. The fisheries have always been important, and in no European fishmarket is the produce more varied. Sardines and tunny are cured and tinned for export. In addition to a fleet of about 600 sailing boats, the Tagus is the headquarters of a small fleet of steam trawlers. The industries of Lisbon include dyeing, distillation of spirits and manufactures of woollen, cotton, silk and linen fabrics, of pottery, soap, paper, chemicals, cement, coals, tobacco, preserved foods and biscuits.

Education and Charity.—Although the seat of the only university in Portugal was fixed at Coimbra in 1537, Lisbon is the educational centre of the Portuguese world, including Brazil.
LISBURN

its chief learned societies are the Society of Medical Sciences, the Geographical Society, the Royal Academy of Sciences, the Academy of Fine Arts, the Royal Conservatory of Music and the Pombeiro de Portugal. The museum of the Academy of Fine Arts contains the largest collection of pictures and statues by native and foreign artists in Portugal. The Geographical Society has gained an international reputation; it possesses a valuable library and museum. The National Library, founded in 1706, contains 400,000 printed books, and upwards of 1000 MSS. There are also colonial, naval, artillerie, natural history and commercial museums, meteorological and astronomical observatories, zoological gardens and an aquarium. Purely educational institutions include the medical, polytechnic, military and naval schools, commercial, agricultural and industrial institutes, a school of art, a central lyceum, a school for teachers, &c. The English college for British Roman Catholics dates from 1628. The Irish Dominicans have a seminary, and Portuguese ecclesiastical schools are numerous. There are hospitals for women, and for contagious diseases, almshouses, orphanages, a foundling hospital and a very large quarantine station on the south bank of the Tagus, founded in 1857 after an outbreak of yellow fever had devastated the city. Foremost among the theatres, circuses and other places of amusement is the royal opera-house of São Carlos, built in 1792-1793 on the model of the Scala at Milan.

Population.—The population of Lisbon, 187,494, in 1789, rose to 301,206 in 1890 and 356,009 in 1900. It includes a large foreign colony, composed chiefly of Spaniards, British, Germans, French, Belgians and immigrants from the Portuguese colonies, among whom are many half-castes. The majority of the Spaniards are domestic servants and labourers from Galicia, whose industrious and easily gained knowledge of the kindred Portuguese language enables them to earn a better livelihood here than in their own homes. The British, German and French communities control a large share of the foreign trade. The Brazilians and colonial immigrants are often merchants and landowners who come to the mother-country to spend their fortunes in a congenial social environment.

The street life of the city is full of interest. The bare-footed, uncleanly fishwives, dressed in black and bearing flat trays of fish on their heads; the Galician water-carriers, with their casks; the bakers, bending beneath a hundredweight of bread slung in a huge basket from their shoulders; the countrymen, with their sombreros, sashes and hard wood quarter-staves, give colour and animation to their surroundings; while the bag-pipes played by peasants from the ends of the streets, the whistles of the knife-grinders, and the distinctive calls of the vendors of fruit, lottery tickets, or oil and vinegar, contribute a babel of sound. For church festivals and holidays the country-folk come to town, the women riding on pinnions behind the men, dressed in shawls, aprons and handkerchiefs of scarlet or other vivid hues, and wearing the strings of coins and ornaments of exquisite gold and silver filigree which represent their savings or dowries. The costumes and manners of all classes may be seen at their best in the great bull-ring of Campo Pequeno, a Mauresque building which holds many thousands of spectators. A Lisbon bull-fight is a really brilliant exhibition of athletic skill and horsemanship, in which amateurs often take part, and neither horses nor bulls are killed. There is a Tauromachie Club solely for amateurs.

For Lisbon is a modification of the ancient name Olissipo, also written Ulissipó. According to the mythological story of a city founded by Odysseus (Ulysses) in Iberia, which, however, according to Strabo, was placed by ancient tradition rather in the mountains of Turdetania (the extreme south of Spain). Under the Romans Olissipo became a municipium with the epithet of Felicitas Julia, but was inferior in importance to the less ancient Emerita Augusta (Mérida). From 497 to 585 it was occupied by Alaric, and thenceforward by the Visigoths until 711, when it was taken by the Moors. Under the Moors the town bore in Arabic the name of Al Oshkha or Lashbûna. It was the first point of Moslem Spain attacked by the Normans in 844. When Alphonso I. of Portugal took advantage of the decline and fall of the Almoravid dynasty to incorporate the provinces of Estremadura and Alentejo in his new kingdom, Lisbon was the last city of Portugal to fall into his hands, and yielded only after a siege of several months (21st October 1147), in which he was aided by English and Flemish crusaders on their way to Syria. In 1184 the city was again attacked by the Moslems under the powerful caliph Abu Yakhub, but the enterprise failed. In the reign of Ferdinand I., the centre of the town was burned by the Castilian army under Henry II. (1273), and in 1384 the Castilians again besieged Lisbon, but without success. Lisbon became the seat of an archbishop in 1390, the seat of government in 1422. During the 16th century it gained much in wealth and splendour from the establishment of a Portuguese empire in India and Africa. From 1580 to 1640 Lisbon was a provincial town under Spanish rule, and it was from this port that the Spanish Armada sailed in 1588. In 1640 the town was captured by the duke of Braganza, and the independence of the kingdom restored.

For many centuries the city had suffered from earthquakes, and on the 1st of November 1755 the greater part of it was reduced almost in an instant to a heap of ruins. A tidal wave at the same time broke over the quays and wrecked the shipping in the Tagus; fire broke out to complete the work of destruction; between 30,000 and 40,000 persons lost their lives; and the value of the property destroyed was about £20,000,000. The shock was felt from Scotland to Asia Minor. Careful investigation by Daniel Sharpe, an English geologist, has delimited the area in and near Lisbon to which its full force was confined. Lisbon is built in a geological basin of Tertiary formation, the upper portion of which is loose sand and gravel destitute of organic remains, while below these are the so-called Almada beds of yellow sand, calcareous sandstone and blue clay rich in organic remains. The Tertiary deposits, which altogether cover an area of more than 200 sq. m., are separated near Lisbon from rocks of the Secondary epoch by a great sheet of basalt. The uppermost of these Secondary rocks is the hippurite limestone. It was found that no building on the blue clay escaped destruction, none on any of the Tertiary deposits escaped serious injury, and all on the hippurite limestone and basalt were undamaged. The line at which the earthquake ceased to be destructive thus corresponded exactly with the boundary of the Tertiary deposits.

At the beginning of the 19th century the French invasion, followed by the removal of the court to Rio de Janeiro, the Peninsular War, the loss of Brazil and a period of revolution and dynastic trouble, resulted in the utter decadence of Lisbon, from which the city only recovered after 1850 (see PORTUGAL: History).

Bibliography.—Every book which deals with the topography, trade or history of Portugal as a whole necessarily devotes a portion of its space to the capital; see PORTUGAL: Bibliography. The following treat more exclusively of Lisbon: A. Dayot, Lisbonne (No. ix. of the “Capitales du monde” series) (Paris, 1892); Freire de Oliveira, Elementos para la historia do municipio de Lisboa (9 vols., Lisbon, 1888-1908); J. de Castilho, Lisboa antiga (7 vols., Lisbon, 1890), and (by the same author) A Ribeira de Lisboa (Lisbon, 1893).

LISBURN, a market town, and cathedral city of Co. Antrim, Ireland, situated in a beautiful and fertile district on the Lagan, and on the Great Northern railway, 8 m. S.S.W. of Belfast. Pop. (1901) 11,461. Christ Church (1622) which possesses a fine octagonal spire, is the cathedral church of the united Protestant dioceses of Down, Connor and Dromore, and contains a monument to Jeremy Taylor, who was bishop of the see. The public park was presented to the town by Sir Richard Wallace (d. 1890), and after his death the castle gardens were also given to the town. The staple manufacture is linen, especially damasks and muslins, originally introduced by Hugenots. There are also bleaching and dyeing works, and a considerable agricultural trade. The town is governed by an urban district council. The ruins of Castle Robin, 2 m. N. of the town, stand on a summit of the White Mountains, and the building dates from the time of Queen Elizabeth. At Drumbo, 3½ m. E. of Lisburn, is one of the finest examples of early fortification in Ireland, known as the Giant’s Ring, with a cromlech in the centre. Here are also a round tower and the remains of a church ascribed to St. Patrick.
LISIEUX—LISLE

Lisieux, a town of north-western France, capital of an arrondissement in the department of Calvados, 30 m. E. of Caen by rail. Pop. (1906) 15,194. Lisieux is prettily situated in the valley of the Touques at its confluence with the Orbiqet. Towers of the 10th century, relics of the old fortifications, remain, and some of the streets, bordered throughout by houses of the 15th and 16th centuries, retain their medieval aspect. The church of St Peter, formerly a cathedral, is reputed to be the first Gothic church built in Normandy. Begun in the latter half of the 12th century it was completed in the 13th and 16th centuries. There is a lantern-tower over the crossing and two towers surmount the west façade, one only of which has a spire, added towards the end of the 16th century. In the interior there is a Lady-Chapel, restored in the 15th century by Bishop Pierre Cauchon, one of the judges of Joan of Arc. The church of St Jacques (late 15th century) contains beautiful glass of the Renaissance, some remarkable stalls and old frescoes, and a curious picture on wood, restored in 1681. The church of St Désir (18th century) once belonged to a Benedictine abbey. The old episcopal palace near the cathedral is now used as a court-house, museum, library and prison, and contains a beautiful hall called the salle dorée. Lisieux is the seat of a sub-prefect, and has tribunals of first instance and of commerce, a chamber of arts and manufactures, a board of trade arbitrators and a commercial college. Its manufactures of woollens are important, and bleaching, wool and flax-spinning, tanning, brewing, timber-sawing, metal-foundling, and the manufacture of machinery, hosiery and boots and shoes are carried on; there is trade in grain, cattle and cheese.

In the time of Caesar, Lisieux, under the name of Noviomagus, was the capital of the Lexovii. Though destroyed by the barbarians, by the 6th century it had become one of the most important towns of Neustria. Its bishopric, suppressed in 802, dates from that period. In 877 it was pillaged by the Normans; and in 911 was included in the duchy of Normandy by the treaty of St Clair-sur-Epte. Civil authority was exercised by the bishop as count of the town. In 1136 Geoffrey Plantagenet laid siege to Lisieux, which had taken the side of Stephen of Blois. The town was not reduced till 1141, by which time both it and the neighbourhood had been brought to the direst extremities of famine. In 1152 the marriage of Henry II. of England to Eleanor of Guînesse, which added so largely to his dominions, was celebrated in the cathedral. Thomas à Becket took refuge here, and some vestments used by him are preserved in the hospital chapel. Taken by Philip Augustus and reunited to France in 1203, the town was a frequent subject of dispute between the contending parties during the Hundred Years' War, the religious wars, and those of the League.

LISKEARD, a market town and municipal borough in the Bodmin parliamentary division of Cornwall, England, 15 m. W.N.W. of Plymouth, on the Great Western and the Liskeard and Looe railways. Pop. (1901) 4010. It lies high, above two small valleys opening to that of the Looe river, in a hilly, picturesque district. The Perpendicular church of St Martin, with a tower of earlier date, having a Norman arch, is one of the largest ecclesiastical buildings in the county. The site of a castle built by Richard, brother of Henry III. and earl of Cornwall, is occupied by public gardens. At the grammar school, which formerly occupied a building in those gardens, Dr John Wolcot, otherwise known as Peter Pindar, was educated. Liskeard was formerly an important mining centre. Its manufactures include leather and woolen goods, and there are iron foundries. The borough is under a mayor, 4 aldermen and 12 councillors. Area, 2704 acres.

Liskeard (Liscarret) was at the time of the Domesday Survey an important manor with a mill rendering 12d. yearly and a market rendering 4s. By the Conqueror it had been given to the count of Mortain by whom it was held in demesne. Ever since that time it has passed with the earldom or duchy of Cornwall. The fertility of its soil and the river Looe probably led to early settlement at Liskeard. Richard, King of the Romans, recognized its natural advantages and built the manor house or castle and resided there occasionally. In 1240 he constituted Liskeard a free borough and its burgesses freemen with all the liberties enjoyed by the burgesses of Launceston and Helston. In 1266 he granted fairs to the Feasts of the Assumption and St Matthew. His son Edmund earl of Cornwall in 1275 granted to the burgesses for a yearly rent of £18 (sold by William III. to Bodmin) the borough in fee farm with its mills, tolls, and pleas, pleas of the crown excepted. Liskeard which made a coinage town for tin in 1304 Edward the Black Prince secured to the burgesses in 1355 immunity from pleas outside their franchise for trespass done within the borough. Queen Elizabeth granted a charter of incorporation in 1580 under which there were to be a mayor, recorder and eight councillors. This charter was surrendered to Charles II. in 1680 and a new one granted by his brother under which the corporation became a self-elected body. From 1295 to 1832 Liskeard sent two members to the House of Commons. The parliamentary franchise, at first exercised by the burgesses, was vested by James' charter in the corporation and freemen. By determining to admit no new freemen the voters became reduced to between 30 and 60. Sir Edward Coke was returned for this borough in 1620, and Edward Gibbon the historian in 1774. In 1832 Liskeard was deprived of one of its members and in 1885 it became merged in the county.

Most of the fairs already mentioned a third was added by Elizabeth's charter to be held on Ascension Day. These are still among the most considerable cattle fairs in the county. The same charter ratified a market on Mondays and provided for another on Saturdays. The latter is now held weekly, the former twice a month. The fair mill at Lamerton mentioned in the charter of 1275, and probably identical with the mill of the Domesday Survey, is still driven by water.

Lisle, Alice (c. 1614-1683), commonly known as Lady Alice Lisle, was born about 1614. Her father, Sir White Beckenshaw, was descended from an old Hampshire family; her husband, John Lisle (d. 1664), had been one of the judges at the trial of Charles I., and was subsequently a member of Cromwell's House of Lords—hence his wife's courtesy title. Lady Lisle seems to have leaned to Royalism, but with this attitude she combined a decided sympathy with religious dissent. On the 20th of July 1685, a fortnight after the battle of Sedgemoor, the old lady consented to shelter John Hickes, a well-known Nonconformist minister, at her residence, Myoles Court, near Ringwood. Hickes, who was a fugitive from Monk's army, brought with him Richard Nethorpe, also a preacher. The two men passed the night at Myoles Court, and on the following morning were arrested, and their hostess, who had denied their presence in the house, was charged with harbouring traitors. Her case was tried by Judge Jeffreys at the opening of the "Bloody Assizes" at Winchester. She pleaded that she had no knowledge that Hickes's offence was anything more serious than religious preaching, that she had known nothing previously of Nethorpe (whose name was not included in the indictment, but was, nevertheless, mentioned to strengthen the case for the Crown), and that she had no sympathy with the rebellion. The jury reluctantly found her guilty, and, the law recognizing no distinction between principals and accessories in treason, she was sentenced to be burned. Jeffreys ordered that the sentence...
should be carried out that same afternoon, but a few days' respite was subsequently granted, and James II. allowed beheading to be substituted for burning. Lady Lisle was executed in Winchester market-place on the 2nd of September 1685. By many writers her death has been termed a judicial murder, and one of the first acts of parliament of William and Mary reversed the attainer on the ground that the prosecution was irregular and the verdict injuriously exerted "by the menaces and violence and other illegal practices" of Jeffrey. It is, however, extremely doubtful whether Jeffrey, for all his gross brutality, exceeded the strict letter of the existing law.

LISMORE, an island in the entrance to Loch Linne, Argyllshire, Scotland. 5° N.W. of Oban. Pop. (1901) 500. It lies S.W. and N.E., is 9½ m. long and 1¼ m. broad, and has an area of 6600 acres. It divides the lower end of the loch into two channels, the Lynn of Morvern on the W. and the Lynn of Lorne on the E. The name is derived from the Gaelic Lios Mor, "great garden." Several ruined castles stand on the coast, and the highest point of the island is 500 ft. above the sea. The soil is of such a nature as to raise various kinds of wheat and horned grasses, with dairy produce, form the bulk of the trade. Steamers call at Achnacrosan. A Columban monastery was founded in Lismore by St Moluag about 592. About 1200 the see of Argyll was separated from Dunkeld by Bishop John, "the Englishman," and Lismore soon afterwards became the seat of the bishop of Argyll, sometimes called "Episcopis Lismoriensis," quite distinct from the bishop of the Isles (Sudreys and Isle of Man), called "Episcopis Sodoriensis" or "Insularum," whose see was divided in the 14th century into the English bishopric of Sodor and Man and the Scottish bishopric of the Isles. The Rev. John Macaulay (d. 1786), grandfather of Lord Macaulay, the historian, and the Rev. Donald M'Nicol (1735-1802), who took up the defence of the Highlands against Dr Johnson, were ministers of Lismore.

For the Book of the Dean of Lismore see Celt: Scottish Gaelic Literature.

LISMORE, a town of Rous county, New South Wales, Australia, 320 m. direct N. by E. of Sydney. Pop. (1901) 4378. It is the principal town of the north coast district, and the seat of a Roman Catholic bishop. The surrounding country is partly pastoral, and partly agricultural, the soil being very fertile. The town has a cathedral, school of art, and other public buildings, while its industrial establishments include saw-mills, sugar-mills, butter factories and an iron foundry. Standing at the head of navigation of the Richmond river, Lismore has a large export trade in dairy produce, poultry, pigs, and pine and cedar timber.

LISMORE, a market town and seat of a diocese in Co. Waterford, Ireland, 43 m. W.S.W. of Waterford by the Waterford and Mallow branch of the Great Southern & Western Railway. Pop. (1901) 1538. It is beautifully situated on a steep eminence rising abruptly from the Blackwater. At the verge of the rock on the western side is the old baronial castle, erected by King John in 1185, which was the residence of the bishops till the 14th century. It was besieged in 1641 and 1643, and in 1645 it was partly destroyed by fire. The present building is largely modern, while the portico was designed by Inigo Jones. To the east, on the summit of the height, is the cathedral of St Carthagh, of various dates. There are portions probably of the 12th and 13th centuries, but the bulk of the building is of the 17th century, and considerable additions, including the tower and spire, were made in the 19th. There are a grammar school, a free school and a number of charities. Some trade is carried on by means of the river, and the town is the centre of a salmon fishery district.

The original name of Lismore was Maghscait. A monastery founded here by St Carthagh in 633 became so celebrated as a seat of learning that it is said no fewer than twenty churches were erected in its vicinity. The bishopric, which is said to have originated with this foundation, was united to that of Waterford in 1365. In the 9th and beginning of the 10th centuries the town was repeatedly plundered by the Danes, and in 978 the town and abbey were burned by the men of Osory. Henry II., after landing at Waterford, received in Lismore castle the allegiance of the archbishops and bishops of Ireland. In 1518 the manor was granted to Sir Walter Raleigh, from whom it passed to Sir Richard Boyle, afterwards earl of Cork. From the ears of Cork it descended by marriage to the dukes of Devonshire. It was incorporated as a municipal borough in the time of Charles II., when it also received the privilege of returning members to parliament, but at the Union in 1800 it was disfranchised and also ceased to exercise its municipal functions.

LISSA (Serbo-Croatian Vis; Lat. Issa), an island in the Adriatic sea, forming part of Dalmatia, Austria. Lissa lies 31 m. S. by W. of Spalato, and is the outermost island of the Dalmatian Archipelago. Its greatest length is 10½ m.; its greatest breadth 4½ m. In shape it is a long, roughly drawn parallelogram, surrounded by a wall of rock, which incloses the fertile central plain, and is broken, on the north, west and east by natural harbours. Its culminating point is Mount Hum (1942 ft.), on the south-west. The island, which belongs to the adminstration of the Adriatic, is divided between two communities: Lissa, named after the chief town, Lissa (Vis), on the north, and Comisa (Komiza), on the west. Lissa, the capital, has a strongly fortified harbour. It contains the palace of the old Venetian counts Gariboldi, the former residence of the English governor, the monastery of the Minorites and at a little distance to the west the ruins of the ancient city of Issa. The islanders gain their livelihood by viticulture, for which Issa was once famous, by sardine fishing and by the distillation of rosemary oil. Pop. (1900) 9218, of whom 3061 belonged to the town and commune of Lissa, and 4657 to Comisa.

Issa is said to have been settled by people from Lesbos, the Issa of the Aegan. The Parians, assisted by Dionysius the Elder of Syracuse, introduced a colony in the 4th century B.C. During the First Punic War (265-241 B.C.) the Issaees with their beaked ships helped the Roman Duilius; and the great republic, having defended their island against the attacks of Agnon of Ilyria and his queen Teuta, again found them serviceable allies in the war with Philip of Macedon (c. 215-211). As early as 296 the Venetians ruled the island, and, though they retired for a time before the Ragusans, their power was effectively established in 1278. Velo Selo, then the chief settlement, was destroyed by Ferdinand of Naples in 1483 and by the Turks in 1571. The present city arose shortly afterwards. During the Napoleonic wars, the French held Issa until 1811, and during this period the island prospered greatly, its population increasing from 4000 to 12,000 between 1808 and 1811. In the latter year the French squadron was defeated by the British (see below); though in the same year a French fleet, flying British colours, entered Lissa, and only retired after burning 64 merchantmen. Thenceforward the island gained a valuable trade in British goods, which, being excluded from every port under French control, were smuggled into Dalmatia. In 1812 the British established an administrative system, under native officials, in Lissa and the adjoining islands of Curzola and Lagosta. All three were ceded to Austria in 1815.

Battles of Issa—Two naval actions have been fought in modern times near this island. The first took place on the 13th of March 1811, and was fought between a Franco-Venetian squadron, under the command of an officer named Dubourdieu (of whom little or nothing else is known), and Captain (afterwards Sir) William Hoste with a small British force. The Franco-Venetian squadron (Venice was then part of the dominions of the emperor Napoleon) consisted of six frigates, of which four were of forty guns, and of five corvettes or small craft. The British squadron was composed of three frigates, the "Amphion," 32 (Captain William Hoste), the "Cerberus" (Captain Henry Whitty) and the "Active," 38 (Captain James A. Gordon). With them was the "Volage," 22 (Captain Phipps Hornby). The action has a peculiar interest because the French captain imitated the method of attack employed by Nelson at Trafalgar. He came down from windward in two lines parallel to one another.
and at an angle to the British squadron. Captain Hoste was not compelled to lie still as the allies did at Trafalgar. He stood on, and as the two French lines had to overtake him as he slipped away at an angle to their course, one of them got in the way of the other. Captain Hoste materially forwarded the success of his manoeuvre by leading the foremost French ship, the "Favorite," on to a reef, which was known to himself, but not to the enemy. Both squadrons then turned, and the Franco-Venetians falling into great confusion were defeated in spite of the gallant fighting of the individual ships. Two prizes were taken and Dubourdieu was killed.

The second naval battle of Lissa was fought between the Austrian and Italian navies on the 20th of July 1866. The island, then in possession of the Austrians, was attacked by an Italian squadron from Ancona of 12 ironclads and 21 wooden vessels. One of the ironclads was damaged in a bombardment of the forts, and two were detached on other service, when an Austrian squadron of 7 ironclads, one unarmoured warship the "Kaiser" and a number of small craft which had left Fasano under the command of Admiral Tegethoff came to interrupt their operations. The Italian admiral Persano arranged his ships in a single line ahead, which allowing for the necessary space between them meant that the Italian formation stretched for more than 2 m. Just before the action began Admiral Persano shifted his flag from the "Ré d'Italia," the fourth ship in order from the van, to the ram "Affondatore," the fifth. This made it necessary for the "Affondatore" and the ships astern to shorten speed, and, as the leading vessels stood on, a gap was created in the Italian line. Admiral Tegethoff, who was on the port bow of the Italians, attacked with his squadron in three divisions formed in obtuse angles. The Italians opened a very rapid and ill-directed fire at a distance of 1000 yds. The Austrians did not reply till they were at a distance of 300 yds. Under Tegethoff's vigorous leadership, and aided by the disorder in the Italian line, the Austrians brought on a brief, but to the Italians destructive, mêlée. They broke through an interval between the third and fourth Italian ships. The unarmored Austrian ships headed to attack the unarmed Italians in the rear. At this point an incident occurred to which an exaggerated importance was given. The Italian ironclad "Ré d'Algeria" of 5000 tons, in the rear of the line, stood out to cover the unarmored squadron by ramming the Austrians. She was herself rammed by the wooden "Kaiser" (5000 tons), but received little injury. The Italian "Ré d'Algeria" was much injured. The "Kaiser" and the wooden vessels then made for the protection of fort San Giorgio on Lissa unpursued. In the centre, where the action was hottest, the Austrian flagship "Ferdinand Max" of 500 tons rammed and sank the "Ré d'Italia." The Italian "Palestro" of 2000 tons was fired by a shell and blew up. By midday the Italians were in retreat, and Tegethoff anchored at San Giorgio. His squadron had suffered very little from the wild fire of the Italians. The battle of the 20th July was the first fought at sea by modern ironclad steam fleets, and therefore attracted a great deal of attention. The sinking of the "Ré d’Italia" and the ramming of the "Portogallo" by the "Kaiser" gave an immense impulse to the then popular theory that the ram would be a leading, if not the principal, weapon in modern sea warfare. This calculation has not been borne out by more recent experience, and indeed was not justified by the battle itself, in which the attempts to ram were many and the successes very few. The "Ré d’Italia" was struck only because she was suddenly and most injudiciously backed, so that she had no way on when charged by the "Ferdinand Max."

For the first battle of Lissa see James’s Naval History, vol. v. (1837). A clear account of the second battle will be found in Sir S. Eardley-Wilmot’s Development of Navies (London, 1892); see also H. W. Wilson’s Ironclads in Action (London, 1896).

LISSA—LIST, F.

Chiefly of shoes, machinery, liqueurs and tobacco; it also possesses a large steam flour-mill, and carries on brisk trade in grain and cattle.

Lissa owes its rise to a number of Moravian Brothers who were banished from Bohemia by the emperor Ferdinand I. in the 16th century and found a refuge in a village on the estate of the Polish family of Leszczyński. Their settlement received municipal rights in 1561. During the Thirty Years' War the population was reinforced by other refugees, and Lissa became an important commercial town and the chief seat of the Moravian Brothers in Poland. Johann Amos Comenius was long rector of the celebrated Moravian school here. In 1656 and 1707 Lissa was burned down.

LIST, FRIEDRICH (1789-1846), German economist, was born at Reutlingen, Württemberg, on the 6th of August 1869. Unwilling to follow the occupation of his father, who was a prosperous tanner, he became a clerk in the public service, and by 1816 had risen to the post of ministerial under-secretary. In 1817 he was appointed professor of administration and politics at the university of Tübingen, but the fall of the ministry in 1819 compelled him to resign. As a deputy to the Württemberg chamber, he was active in advocating administrative reforms. He was eventually expelled from the chamber and in April 1822 sentenced to ten months' imprisonment with hard labour in the fortress of Asperg. He escaped to Alsace, and after visiting France and England returned in 1824 to finish his sentence, but was released on appeal. There he remained, and in 1825 he resided from 1825 to 1832, first engaging in farming and afterwards in journalism. It was in America that he gathered from a study of Alexander Hamilton's work the inspiration which made him an economist of his pronounced "National" views. The discovery of coal on some land which he had acquired made him financially independent, and he became United States consul at Leipzig in 1832. He strongly advocated the extension of the railway system in Germany, and the establishment of the Zollverein was due largely to his enthusiasm and ardour. His latter days were darkened by many misfortunes; he lost much of his American property in a financial crisis, ill-health also overtook him, and he brought his life to an end by his own hand on the 30th of November 1846.

LIST, Johann Christian, first found the highest places in economic thought as applied to practical objects. His principal work is entitled Das Nationale System der Politischen Ökonomie (1841). Though his practical conclusions were different from those of Adam Müller (1779-1829), he was largely influenced not only by Hamilton but also by the general mode of thinking of that writer, and by his strictures on the doctrine of Adam Smith. It was particularly against the cosmopolitan principle in the modern economical system that he protested, and against the absolute doctrine of free trade, which was in harmony with that principle. He gave prominence to the national idea, and insisted on the special requirements of each nation according to its circumstances and especially to the degree of its development.

He refused to Smith's system the title of the industrial, which he held historically to the mercantilism age, and designated the former as the "exchange-value system." He denied the parallelism asserted by Smith between the economic conduct proper to an individual and to a nation, and held that the immediate private interest of the separate members of the community would not lead to the highest good of the whole. That the nation was an existence, standing between the individual and humanity, and formed into a unity by its language, manners, historical development, culture and existence, and that the unity must be the first condition of the security, wellbeing, progress and civilization of the individual; and private economic interests, like all others, must be subordinated to the maintenance, completion and strengthening of this nationality.

That the system, having a continuous life, its true wealth must consist—and this is List’s fundamental doctrine—not in the quantity of exchange-values which it possesses, but in the full and many-sided development of its productive powers. Its economic education should be more important than the immediate production of values, and it might be right that one generation should sacrifice its gain and enjoyment to secure the strength and skill of the future. In the sound and normal condition of a nation which has attained
economic maturity, the three productive powers of agriculture, manufactures and commerce should be alike developed. But the two latter factors are superior in importance, as exercising a more effective and fruitful influence on the whole culture of the nation, as well as on its independence. Navigation, railways, and technical arts, connect themselves specially with these factors; whilst in a purely agricultural state there is a tendency to stagnation. But for the growth of the higher forms of industry all countries are required. In the first place, the State must itself be open to the occupation of trade. Furthermore, the territorial states have a natural monopoly in the production of certain raw materials; and thus between these two groups of countries a division of labour and confederation of powers spontaneously takes place.

List then goes on to explain his theory of the stages of economic development through which the nations of the temperate zone, which are furnished with all the necessary conditions, naturally pass. These stages are: (1) pastoral, (2) agriculture, (3) industry united with manufactures; whilst in the final stage agriculture, manufactures and commerce are combined. The economic task of the state is to bring into existence through legislative and administrative action the conditions required for the progress of the nation through these stages. Out of this view arises List's scheme of industrial politics. Every nation, according to him, should begin with free trade, stimulating and improving its agriculture by intercourse with richer and more cultivated nations, importing foreign manufactures and exporting raw products. When it is economically so far advanced that it can manufacture for itself, then a system of protection should be established, which will lead to independent political development. But this must be done completely, and save them from being overpowered in their earlier efforts by the competition of more matured foreign industries in the home market. When the national industries have grown strong enough to look after themselves, then the industrial empire can be made self-sufficient and free trade should again become the rule, and the nation be thus thoroughly incorporated with the universal industrial union. What a nation loses for a time in exchange values during the transition to the next stage it gains in productive power—the temporary expenditure being strictly analogous, when we place ourselves at the point of view of the life of the nation, to the cost of the industrial education of the individual. The whole scheme of List's political economy was that for Germany she needed for her economic progress an extended and conveniently bounded territory reaching to the sea-coast both on north and south, and a vigorous expansion of manufactures and commerce, and that the latter must be fostered by the state, for a customs union comprising all German lands, and a German marine with a Navigation Act. The national German spirit, rising after independence and power through union, and the national industry, awakening from its lethargy, and eager to recover lost ground, were favourable to the success of List's book, and it produced a great sensation.

He ably represented the tendencies and demands of his time in his own country; his work had the effect of fixing the attention of the state on the localisation of industry, and of giving practical men generally, on questions of political economy; and his ideas were undoubtedly the economic foundation of modern Germany, as applied by the practical genius of Bismark.

LIST (O. E. list, a Teutonic word, cf. Dut. lijst, Ger. Leiste, adapted in Ital. lista and Fr. liste), properly a border or edging. The word was thus formerly used of a geographical or boundary or frontier and of the lobe of the ear. In current usage "list" is the term applied to the selvage of a piece of cloth, the edging. I.e. of a web left in an unfinished state or of different materials from the main body of the fabric. A list can be torn or wound up, as a roll, or it can be made up, or used for forming a seam. A similar edging prevents unravelling. The material, cut off and collected, is known as "list," and is used as a soft cheap material for making slippers, padding cushions, &c. Until the employment of rubber, list was used to stuff the cushions of billiard tables. The same word probably appears, in a plural form "lists," applied to the barriers or palisades enclosing a space of ground set apart for tilting (see TOURNAMENT). It is thus used of any place of contest, and the phrase "to enter the lists" is frequently used in the sense of "to challenge." The word in this application was taken directly from the O. Fr. lisse, modern lice, in Med. Lat. Liceae. This word is usually taken to be a Romanic adaptation of the Teutonic word. In medieval fortifications the lists were the palisades forming an outwork in front of the main walls of a castle or other fortified place, and the word was also used of the space enclosed between the palisades and the enceinte; this was used for exercising troops, &c. From a transference of "list," meaning edge or border, to a "strip" of paper, parchment, &c., containing a "list" of names, numbers, &c., comes the use of the word for an enumeration of a series of names of persons or things arranged in order for some specific purpose. It is the most general word for such an enumeration, other words, such as "register," "schedule," "inventory," "catalogue," having usually some particular connotation. The chief early use of list in this meaning was of the roll containing the names of soldiers; hence to "list a soldier" meant to enter a recruit's name for service, in modern usage "to enlist." There are numerous particular applications of "list," as in "civil list" (q.v.), "active or retired list" in the navy or army. The term "free list" is used of an enumeration of such commodities as may at a particular time be exempt from the revenue laws imposing an import duty.
